In the next series of experiments, some of the other solutions commonly used in the treatment of varicose veins were tested in a similar manner to the salicylate, particularly sodium morrhuate, quinine and urethane, and glucose. Animals injected with c.cm. of a 5 per cent. solution of sodium morrhuate showed changes in general similar to those following salicylate injection—i.e., a general dilatation of the vessels of the ear, the rapid formation of an intravenous clot, and subsequent œdema of the ear; and microscopically, degenerative changes in the vein wall (Fig. 5), and an acute inflammatory reaction the surrounding tissues (Fig. 6). Five per cent. sodium morrhuate differed from the 30 per cent. salicylate in that it was not such a certain thrombotic agent. The solution of quinine and urethane used was one containing 13 per cent. of quinine and 6½ per cent. urethane, the usual strength employed clinically. The difficulty in testing this solution was that in the rabbit the margin between a thrombotic dose and a lethal dose is small. But in the positive cases the changes produced in the ear were similar to those following injection of sodium salicylate and sodium morrhuate. The histological findings thus suggest that the general mechanism by which thrombosis produced by these three solutions is similar.

The other solution tested was glucose. A 60 per cent. solution, the strength used clinically, had no effect when injected into the marginal ear-vein of rabbits. A solution was therefore made up twice this strength, the result being a thick syrupy fluid that only passed through a hypodermic needle with difficulty. Even with a solution of this strength thrombosis rarely resulted, though there was often marked œdema of the ear. While conclusions derived from animal experiment do not necessarily apply to man, in the type of experiment here described glucose is certainly a much less efficient thrombosing agent than the other solutions.

MODE OF ACTION.

The next point for consideration is the means by which these solutions produce intravascular coagulation. The first thing to exclude experimentally was a purely traumatic effect from the introduction of the needle into the vein. This was done by injecting a series of control animals with dilute solutions of sodium salicylate and other substances under conditions similar to those of the main experiments, when it was found that any traumatic coagulum was strictly localised to the site of puncture. A simple traumatic effect having been excluded, there are four possible explanations of the thrombotic action of the solutions: (1) that they have a direct coagulating action on the blood; (2) that the coagulation results from the inflammatory reaction set up; (3) that it results from a physical action of the solutions on the vein wall; and (4) that it results from a chemical action on the vein wall.

(1) It was pointed out by Sicard, when he first began to use the method of intravenous injections for varicose veins, that the solutions he used had no direct coagulating action on the blood, and it is easy to carry out a simple series of experiments in a test-tube to confirm this.

Thus 30 per cent. sodium salicylate and freshly drawn rabbit's blood were mixed in a test-tube, and the rate of coagulation at room temperature compared with a similar mixture of normal saline and blood. With one part of sodium salicylate to one of blood, slow hæmolysis took place which was complete in about 12 minutes. When the concentration was reduced to one part sodium salicylate to two of blood, the mixture was still fluid at the end of 30 minutes, when a little hæmolysis was beginning to occur, though the control saline and blood mixture had completely clotted in 12 minutes.

The direct action of sodium salicylate is therefore that of an anticoagulant rather than a coagulant, and it is also a slow hæmolytic agent.

Similar experiments were performed with quinine and urethane and blood, again using saline as a control.

In order to dissolve the quinine and urethane, which tends to crystallise out at room temperature, it is necessary to warm it, so the saline was also warmed in the same water-bath. Heat accelerates the clotting process, and the control tube had firmly clotted in three minutes. Quinine and urethane and blood, on the other hand, mixed in equal parts, was still quite fluid and apparently unchanged at the end of half an hour, when the experiment was abandoned. A similar result was obtained with one part of quinine and urethane to two of blood.

Sodium morrhuate also has no direct coagulating action in vitro, but is a powerful hæmolytic agent, the addition of 1 c.cm. of a 5 per cent. solution to 1 c.cm. of blood resulting in almost immediate and complete hæmolysis. In all these solutions, therefore, a direct coagulating action on the blood can be excluded as the cause of the intravenous thrombosis.

(2) As for the second possible explanation, the clot has usually formed some time before the histological signs of acute inflammation appear; and, on the other hand, in some of the animals a well-marked inflammatory reaction was present without thrombosis. The actual inflammatory reaction can therefore be excluded as the cause of the thrombosis, though it probably plays an important part in securing the adhesion and rapid organisation of the clot.

(3) The theoretical objection to the third possibility—that the clotting depends on some physical phenomenon such as osmosis—is the fact that the solution is in gross contact with the vein wall for such a short time. But more positive evidence against osmosis is afforded by the fact that, in the experiments mentioned above, very strong solutions of glucose, which would have a high osmotic pressure, proved such unreliable thrombotic agents. Though osmosis might play a part under conditions of marked stasis, in the average case it is probably not the important factor.

(4) We are thus left with the explanation that the thrombosis is due to the chemical action of the injected fluids on the vein wall; a chemical process would more easily than a physical explain the damage to the vein wall resulting from the momentary contact of the solution. As a result of this damage, tissue juice is presumably liberated, which combines with the fibrinogen of the blood. While the general mode of action of the solutions is the same, it does not necessarily follow that the precise chemical changes are the same in all, but of this we have no knowledge.

FIGS. 1 2 3 4

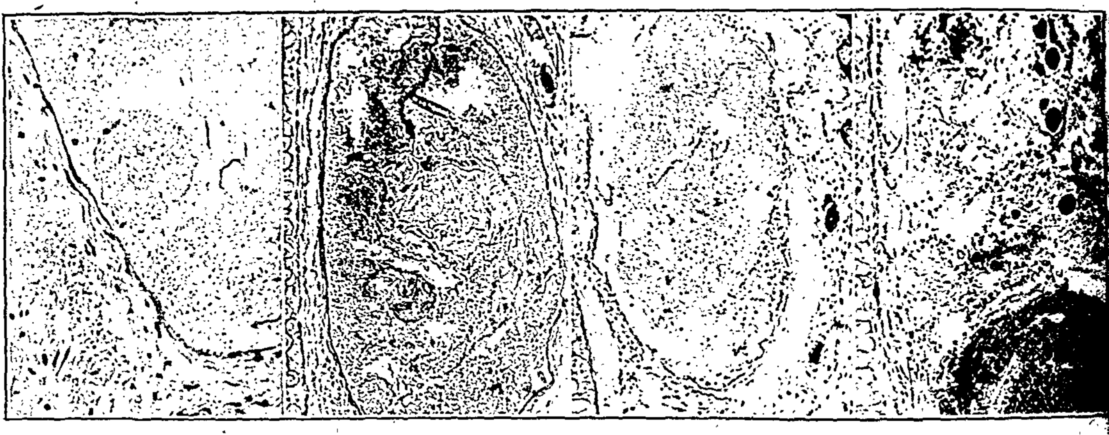

FIG. 1.—High-power view of wall of ear-vein half an hour after the injection of 30 per cent. sodium salicylate, showing in places apparently intact endothelium. (× 235.)

FIG. 2.—Low-power view of same vein as in Fig 1, showing intravascular clot and remains of valve with fibrin network springing from it. The surrounding tissues are unchanged. (× 60.)

FIG. 3.—Low-power view of ear-vein nine hours after the intravenous injection of 30 per cent. sodium salicylate, showing destructive changes in the vein wall and polymorphonuclear leucocytosis in the surrounding tissues. (× 60.)

FIG. 4.—Ear-vein 24 hours after the intravenous injection of 30 per cent. sodium salicylate, showing almost complete destruction of vein wall and intense polymorphonuclear leucocytosis in the surrounding tissues. (× 60.)

Generally speaking, the sequence of events after the injection of varicose veins in man seems similar to that in animals. As a rule, no pain is felt at the time of the injection, though sodium salicylate sometimes provides an exception to this rule. The precise time of occurrence of thrombosis in man is difficult to determine. As judged by the history, it seems to be present in many cases within eight hours or so of the injection. In most cases, a varying amount of discomfort, due to inflammation in and around the vein wall, is complained of some hours after the injection, which is usually worse the next day. There has been no opportunity in this inquiry to make histological observations on the early changes in man, but Hanschell has described a case in which portions of the vein were excised and microscoped 15 minutes, 24 hours, and seven days after the injection. In 15 minutes there was no change in the wall of the vein or its lumen; at 24 hours the vein was filled with clot, there were destructive chan in the intima, and small round-celled infiltration the tissues around the vein, while at seven days clot was undergoing organisation. So that clinically and pathologically the sequence of ev after injections into varicose veins in man wo appear to be generally similar to those already no in the experimental injections.

There is, however, one important difference bet the animal experiments and the thrombosis ind clinically in the treatment of varicose veins, and is the relatively large doses required in the ani experiments. The doses that have had to be gi to produce thrombosis, in spite of the fact that rabbit's vein is so much smaller and thinner, very similar to those employed clinically, and we solutions, such as 15 per cent. sodium salicyl usually have no effect. The explanation of difference probably lies in the rate of blood-flow.

FIGS. 5 6 7 8

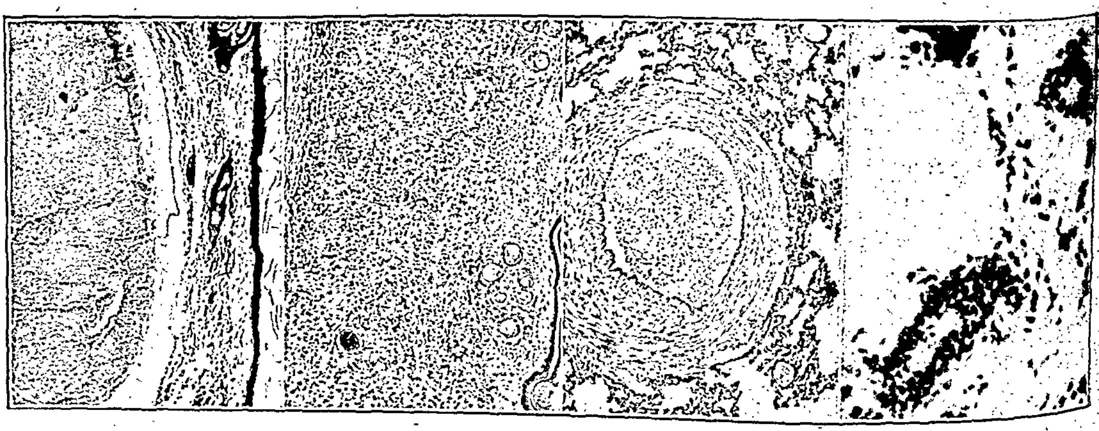

FIG. 5.—Ear-vein 48 hours after the intravenous injection of 5 per cent. sodium morrhuate, showing similar destructive and inflammatory changes. (× 50.)

FIG. 6.—To show the intense leucocytosis in the surrounding tissues 48 hours after the intravenous injection of 5 per cent. sodium morrhuate. (× 50.)

FIG. 7.—Lung artery of rabbit filled with hæmolytic debris and leucocytes after fatal dose of sodium morrhuate. (× 50.)

FIG. 8.—Lung capillaries choked with leucocytes after fatal dose of sodium oleate. (× 300.)

varicose veins we are dealing with a comparatively stagnant column of blood out of the main stream of venous return, whereas in the marginal ear-vein of the rabbit we are dealing with the main venous drainage of an organ with a free and active blood-supply. The practical significance of this difference is that it is probably this same factor—the rate of blood-flow—that in man protects the deep veins from thrombosis when varicose veins are injected, especially in the cases that are occasionally met of widespread superficial thrombosis following a single injection.

Relation between Thrombosis Produced by Injections and Spontaneous Thrombosis.

For comparison with the artificially produced thrombosis three typical and common forms of spontaneous thrombosis may be taken: (1) idiopathic thrombophlebitis arising in varicose and other superficial veins; femoral thrombosis such as is met with after operation; and (3) massive pulmonary embolism.

Thrombophlebitis, spontaneously arising in varicose and other superficial veins, and chemically produced thrombosis clinically indistinguishable. In both there hard tender lump with obvious inflammatory signs around, in both the contained clot is a typical thrombus. The presumption, therefore, is their pathology is similar, and that the spontaneous thrombus is due to some agent acting on the wall of vein. In some cases agent may be something obvious, such as septic process; in others it may be something obscure.

The thrombosis associated with massive pulmonary embolism, on the other hand, presents many differences. Local changes in and around the vein are little marked that in a large number of cases the source of the embolus cannot be found even at post-mortem, while the structure of such a thrombus shows typical architectural arrangement of platelet, leucocyte, and red clot.

A localised femoral thrombosis presents features intermediate between idiopathic thrombophlebitis and pulmonary embolism. Signs of inflammation in and around the vein wall are present, as in the former, but the clot has the same naked-eye and microscopical characteristics as the pulmonary embolus clot.

There are thus three gradations: a spontaneous thrombophlebitis that appears identical pathologically with the chemically produced thrombus, localised femoral thrombosis representing an intermediate stage, and, finally, the thrombosis associated with pulmonary embolism. The difficult thing to determine is whether these three gradations represent different pathological processes, or similar pathological processes of different degrees.

FIGS. 9 10 11

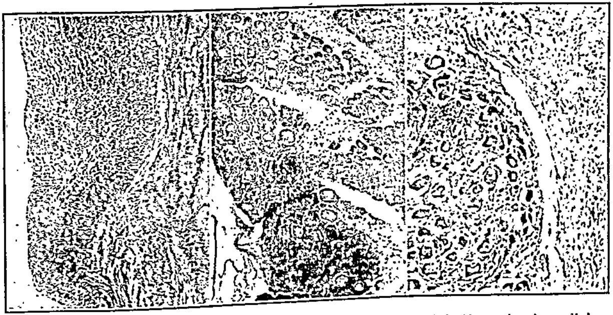

FIG. 9.—Lining of human varicose vein that failed to respond to injections, showing cellular fibrous tissue on fibrosed muscle. (× 35.)

FIG. 10.—Muscle of rabbit 24 hours after injection of sodium morrhuate, showing, from left to right, necrotic muscle remnants, dense aggregations of polymorphonuclear leucocytes, and normal muscle bundles separated by œdema and leucocytes. (× 50.)

FIG. 11.—Muscle of rabbit 21 days after injection of 30 per cent. sodium salicylate, showing dense cellular fibrous tissue intersecting muscle. (× 50.)

The causes of thrombosis are usually classified under three headings: (1) changes in the vessel wall; (2) changes in the blood flow; and (3) changes in the blood itself. Various changes in the blood have been described after operations and other conditions predisposing to thrombosis, such as changes in the coagulation time (Allen), the sedimentation time (Heusser), the leucocyte count (Dawson), and more recently the platelet count (Dawbarn, Earlam, and Evans). But no conclusive experimental proof has yet been brought forward that these changes are directly related to thrombosis. On the other hand, by a combination of the first two factors—stasis and an alteration of the vessel wall—thrombosis can be induced with ease, both clinically in the treatment of varicose veins and experimentally. The injection treatment of varicose veins thus introduces no new principle, but its pathological importance is that it concentrates attention anew on these two factors—stasis and changes in the vessel wall—to the relative overshadowing of changes in the blood.

The Possible Complications of Injection Treatment.

These may be conveniently considered under the following headings: (1) Pulmonary embolism. (2) General symptoms. (3) Failure of a vein to respond to injections. (4) Injection ulcers.

(1) *Pulmonary embolism.*—The theoretical danger of pulmonary embolism was the first and most obvious objection to the injection treatment of varicose veins. Time and experience have proved that it is an excessively rare complication of injection treatment, and the reasons for this are probably twofold. In the first place, varicose veins are a very rare source of emboli at any time. Thus, out of 24 consecutive cases in the post-mortem room of the Middlesex Hospital of pulmonary embolism in which the source of the embolus could be traced, in none was it a varicose vein; and other similar figures could be given. In other words, the stagnant condition in varicose veins that favours thrombosis renders embolism unlikely. The second reason can be found in the histology of injected veins. The thrombus itself after injections is an ordinary red thrombus similar

to other rapidly formed thrombi, but in and around the vein wall there is an inflammatory reaction that probably favours the early adhesion and organisation of the contained thrombus.

(2) *General symptoms.*—Patients after injections for varicose veins are not as a rule upset, and are able to continue their normal occupations; only rarely are the general symptoms severe. In man, therefore, the margin between a therapeutic and a toxic dose is a wide one. It was thought, nevertheless, that a study of the toxic effects of these solutions in animals would be of some interest in indicating the type of reaction that might follow excessive doses in man.

It has been seen that rabbits tolerated comparatively large doses of a strong solution of sodium salicylate. This is in accordance with clinical experience, which is that sodium salicylate is the solution that can be used in the highest concentration and dosage. In some of the animals, however, that received 2 c.cm. of a 30 per cent. solution intravenously, a bright red condition of the whole of both lungs was found, which was seen microscopically to be due to diffuse hæmorrhage and œdema of the lungs, presumably the result of damage to the endothelium of the lung capillaries.

It has been noted already that in vitro sodium morrhuate is a powerful hæmolytic agent, and when it is injected in large doses intravenously in animals a similar hæmolysis may take place in the circulation. This may be shown by the passage of hæmolysed blood in the urine, but more frequently sudden death results, owing to the blockage of the lung arterioles and capillaries with hæmolytic debris and leucocytes. Fig. 7 shows a lung artery from such a case. A similar blockage of the lung capillaries with hæmolytic debris and leucocytes is produced by other unsaturated fatty acids besides sodium morrhuate. The most striking appearances were seen with sodium oleate, which is not used in the treatment of varicose veins but was tested on account of its chemical and physical relationship to sodium morrhuate. Fig. 8 is a microphotograph of the lungs of a rabbit that died after the intravenous injection of 1 c.cm. of a 5 per cent. sodium oleate, showing the lung capillaries choked with leucocytes and debris. The leucocytes are much more marked than in the case of sodium morrhuate, and this may be due to the more marked irritant action of sodium oleate on the endothelium of the lung capillaries, whereby the leucocytes adhere more readily.

Quinine and urethane was the most toxic of the three solutions, 1 c.cm. as a rule killing a 2 kilo rabbit in a few seconds. Microscopically, no definite change can be detected in the lungs, and presumably the action is directly on the heart or central nervous system. These findings can be correlated with the fact that clinically, according to some authors, quinine solutions are the most likely to be associated with idiosyncrasy—i.e., an excessive general reaction from an ordinary therapeutic dose.

It should be emphasised that these toxic effects in animals are obtained with doses that, taking into account the weights of the animals as compared to man, are many times in excess of the ordinary clinical therapeutic dose.

(3) *Failure to respond.*—Fig. 9 is a microphotograph of the varicose vein of a patient who had had injections at weekly intervals for several months without success, so that eventually it was excised. Microscopical examination showed a thickened vein, the inner coat of which was composed of a thick mass of young cellular fibrous tissue, which presumably indicates an inflammatory reaction from the injections. There is clinical evidence to suggest that if for any reason the first few injections fail to act, a conditio of the vein refractory to thrombosis is produced, and it may be that some such anatomical alteration of the vein-lining as is shown by this case may be th cause.

(4) *Injection ulcers.*—This is usually an indication that the solution has been injected into or has leaked into the tissues around the vein. Occasionally, however, it occurs when the solution has been properly injected into the vein, from sloughing of the whole vein wall with the surrounding skin. These ulcers are painful and chronic, and often constitute a much greater nuisance to the patient than the original varicose veins. No solution is exempt from liability.

In animals, the effect of interstitial injection depends on the site injected. Thus, a few minims any of the solutions injected into the tense tissues the rabbit's ear causes inflammation with ulceratio and often sloughing of the whole thickness of th ear. On the other hand, the injection of 1 or 2 c.cm under the loose skin of the thigh sometimes causes similar inflammatory reaction with ulceration, sometimes has no gross effect. The ulceration d not depend on the solution used, since it occurs after the injection of each kind.

After intramuscular injections also, the effect all three solutions—sodium salicylate, sodium mor huate, and quinine and urethane—is essentially t same. Sometimes there was merely an inflammato œdema that gradually subsided, but more often th was an early stage of necrosis and acute inflammati and a late stage of fibrosis. Fig. 10 illustrates appearances in the early stages after injection. the centre is necrosed muscle surrounded by a d mass of acute inflammatory cells, while further the muscle bundles are being separated by œd and loosely arranged inflammatory cells. In late stage of fibrosis (Fig. 11) there was ma fibroblastic proliferation in which the cells of muscle sheaths appeared to be participating. may be presumed that injection ulcers of man sh similar changes.

In conclusion, injection treatment of vari veins has proved a valuable therapeutic mea but the object of this paper is to show that subject is worthy of study not only from this asp but also as a large-scale experiment in the pro tion of thrombosis and aseptic inflammation.

Summary.

(1) The injection of some of the solutions commonly used in the treatment of varicose veins into the marginal ear-vein of rabbits is followed by the early formation of an intravenous clot, destructive changes in the vein wall, and an acute inflammatory reaction in the surrounding tissues. The general mode of action of the different solutions is similar. The intravenous clot is formed when the vein wall is little altered and before inflammatory changes have occurred and is probably due to liberation of tissue juice from the chemical action of the solutions on the vein wall.

(2) After the injection of massive doses of these solutions intravenously in animals, death results in various ways, depending on the particular solution. Interstitial injection produces necrosis and an acute inflammatory reaction, often associated with ulceration, and later a dense fibrosis. In this respect the action of all the commonly used solutions is similar.

(3) The sequence of events after the injection of varicose veins in man seems generally comparable with the experimental findings. In addition, all gradations may be met with between thrombosis, indistinguishable clinically and pathologically from

chemical thrombosis, and a condition like pulmonary embolism with apparently quite different features.

I have pleasure in acknowledging my indebtedness to Prof. J. McIntosh for granting me facilities for carrying out these investigations, and for his kind interest.

A CASE OF ACUTE LYMPHATIC LEUKÆMIA.

BY HENRY MOORE, M.D., D.SC., N.U.I.,
PHYSICIAN TO THE MATER MISERICORDIÆ HOSPITAL, AND CONSULTING PHYSICIAN TO THE NATIONAL MATERNITY HOSPITAL, DUBLIN; PROFESSOR OF MEDICINE, UNIVERSITY COLLEGE, DUBLIN;

AND

W. R. O'FARRELL, L.R.C.P. & S.IREL.,
ATHOLOGIST TO THE MATER MISERICORDIÆ HOSPITAL AND TO ST. MICHAEL'S HOSPITAL, DUN LAOGHAIRE.

A MAN, aged 44, was admitted to the Mater Miseri- rdiæ Hospital on Nov. 19th, 1930. There was a rpuric rash on the front of the chest, on both fore- ons and on the right shin; on the dorsum of the ght foot there was a subcutaneous ecchymosis hich was evidently, from the colour changes, some ys old. The patient did not feel or look very appeared only slightly anæmic and came simply cause of the purpura, which had first appeared e days before admission. His previous history as unimportant except for typhoid fever in 1911. eneral physical examination revealed nothing normal except one abscess shown by X rays at e root of the upper left second molar tooth. he heart, lungs, abdomen, and urine were normal, he blood pressure 150/80, the pulse-rate 72, the ulse regular, and the spleen and liver were pparently not enlarged. The erythrocyte count was 940,000 and the leucocyte count 8600 per c.mm.; he hæmoglobin was 90 per cent. (Sahli), the colour- ndex 1·15, and the platelet count 100,000 per c.mm. The differential leucocyte count showed (per cent.) 13 small lymphocytes, 26 lymphoblast-like cells, 16 arge lymphocytes, 12 polymorphonuclear neutrophile leucocytes, and 3 large mononuclear cells (see Table). Reticulocytes were 0·8 per cent. and there was less than 0·1 mg. of bilirubin per 100 c.cm. of blood. The blood calcium was 9·4 mg. per cent., the clotting time four minutes, the bleeding time from a prick two and a half minutes, and the clot retraction poor. The Wassermann reaction was negative. A fractional test-meal analysis, done because of flatulence and slight glossitis, after the patient had been about three weeks in hospital, showed achlorhydria.

For the first two weeks of observation, purpura was a prominent feature, crops of purpuric spots appearing in some areas of skin while they were fading in others, and there were occasional subcutaneous extravasations of blood of moderate size; later the purpura became less prominent, and in the last two weeks it showed itself only as odd spots. A few days after admission oozing of blood from the gums became troublesome and remained so throughout, except when it disappeared for four or five days after transfusion of blood. There were occasional hæmorrhages from the gastro-intestinal tract (melæna), occasional attacks of hæmaturia and epistaxis, and submucous hæmorrhagic spots frequently appeared on the buccal mucous membrane and soft palate. Blood culture was negative and at no time was there pharyngitis or stomatitis. On Dec. 14th the patient complained of dimness of vision, and ophthalmoscopic examination showed rather extensive retinal hæmorrhages which were pronounced subhyaloid by Dr. D. O'Donoghue; later, retinal, vitreous, and subconjunctival hæmorrhages occurred.

The abscessed tooth was removed by Dr. Ryan a few days after admission and the resulting steady oozing of blood from the alveolus gave some trouble before it was controlled. In the latter half of the illness the temperature sometimes rose to about 100° or 101° F., for a few consecutive days; as time went on the respiratory rate gradually rose to 38 and the heart-rate to 140, and as the anæmia progressed "hæmic" murmurs became audible over the præcordium. The progress was downward, the patient becoming gradually weaker and more anæmic, with temporary partial improvement for some days after transfusion of blood. The spleen was never palpable and the liver edge was for the first time just felt below the costal margin two days before death.

The patient died 67 days after admission and a partial autopsy was permitted. The results of the chief laboratory examinations are recorded in the Table, and the post-mortem findings are discussed below.

The main treatment consisted of transfusion of whole (uncitrated) blood; five such transfusions were given of 320 to 1000 c.cm. each on Nov. 16th, 23rd, and 24th, and Dec. 6th and 18th. Adrephine and adrenalin were used for local treatment of the gums, and hæmoplatic serum for local treatment and by injection; adrenalin was also administered subcutaneously, by mouth and per rectum, and attention was directed to mouth hygiene. Whipple's new liver extract with iron for secondary anæmia, liver extract for pernicious anæmia and whole liver were, in turn, given by mouth, with no beneficial result. Radiostoleum was given by mouth, calcium was given intravenously and by mouth, and iron and hydrochloric acid were given by mouth. These and other drugs were often ordered in desperation and not necessarily because of any scientific basis for their use. The diagnosis of acute ("aleukæmic") lymphatic leukæmia was made after the first blood count, and, we believe, was verified by the subsequent events. Leucopenia appeared after some weeks and was replaced towards the end by lymphocytosis of considerable degree with almost complete agranulocytosis.

The first total leucocyte count immediately impressed the observer by the size of the white blood corpuscles. On examination of the stained films this feature was again prominent, as was also the immature type of many of the white cells. The cells which at once focused attention in the stained smear were of the large lymphocyte type, but these cells bore characteristics which placed them in a category of priority in hæmatopoietic origin to the mature large lymphocyte of the peripheral blood. Apart from the relatively large size of the cells in question—about 18 microns in diameter—even more striking and undoubtedly more cytologically important was their nuclear structure. The nuclei of these cells showed a coarse basi-chromatin stippling, which at the nuclear edge was collected into a fairly dense nuclear membrane. A varying number of nucleoli were present—2 to 3 per cell. The nuclei measured about 16 microns in diameter and showed a graceful, sinuous but comparatively rounded outline. The cytoplasm showed a clear non-granular rim of varying depth, at the widest about 2 microns in diameter. These characteristics enabled the cells to be classified as lymphoblasts. In contradistinction, the nucleus of the myeloblast presents a fine stippled structure and no nuclear membrane, while the nucleus of the pro-monocyte has a fine thread-like basi-chromatin arrangement; no such cells were seen in this patient's blood.

The oxidase reaction has fallen somewhat into disrepute of recent years, owing to its inability to distinguish between the early myeloblast and the early lymphoblast; however, its application failed to demonstrate any granules in the cells under examination. We are inclined, for various reasons, to lay special stress on the morphological characters of the lymphoblasts; they appeared in the blood at an early stage of the disease, they indicated a grave hæmatopoietic lesion, and they increased in numbers through the illness.

The number of lymphoblasts in the blood was considerable on the first examination, comprising 26 per cent. of the differential leucocyte count. The remainder of the differential count showed 43 per cent. of small lymphocytes, 16 per cent. of large lymphocytes, 3 per cent. of large mononuclears, and 12 per cent. of polymorphonuclear neutrophiles. The total leucocyte count only numbered 8600 per c.mm. In order to avoid a tedious repetition of figures the Table has been constructed to show the various important laboratory findings during life.

Through the whole series of observations there was a rapidly progressive anæmia which very soon assumed a "pernicious" type. There was no leucocytosis until near the end; indeed, although there was soon a leucopenia, it must be noted that the fall in leucocytic numbers ran almost parallel on its own level with the decreasing numbers of red blood corpuscles, until in the later examinations a leucocytosis became manifest. The relative lymphocytosis might, at first sight, be taken to be the result of a compensatory over-activity of a normal lymphocytic system. The lymphocytic system showed, however, grave departure from the normal, as evidenced by the occurrence, persistence, and increase of *immature elements—namely, the lymphoblastic* cells. It would seem as if the disease of the lymphocytic system was the basic lesion and that the myeloid disturbance, as evidenced by the decrease of granulocytes and blood platelets, and the megaloblastic anæmia, were secondary. The disease was, therefore, *considered to be a leucosis of the acute lymphatic* type, but exhibiting unusual characters. It was now considered necessary to correlate our findings with the known atypical leukæmias. To quote from Piney[1]:

> "It has long been recognised (Cohnheim) that all the anatomical changes characteristic of 'leukæmia' might occur without any increase in the number of circulating leucocytes, although there were grave alterations in the qualitative composition, as evidenced by the presence of immature cells of a character not found in the normal circulation; this is the 'pseudo-leukæmia' of Cohnheim and the 'aleukæmic leukæmia' of many authors. The essential changes in the hæmatopoietic tissue in these diseases are great cellular overgrowths together with alteration in the structure of the newly formed cells."

Reed,[2] in 1902, described a case of acute lymphatic leukæmia without enlargement of lymphatic glands.

In our case, in the early stages, the colour-index of 1·15 may, we think, fairly be taken as at an extreme maximal normal point. On one occasion (Dec. 9th) it rose to 1·36, but in two days' time it returned to 0·92; on Dec. 15th it rose to 1·25, but in three days' time it fell to 1·15, to reach unity four days later.

---

[1] Piney, A.: Recent Advances in Hæmatology, London, 1931.
[2] Reed, D. M.: Amer. Jour. Med. Sci., 1902, cxxiv., 653.

It is here interesting to cite a case of "aleukæmic" leukæmia reported by Brodribb and Lazarus-Barlow[3] with an erythrocyte count of 2,200,000 per c.cm., a total leucocyte count of 6600 per c.mm., and a colour-index of 1·4.

Divergent views exist as to the significance of megaloblasts in the peripheral blood. Naegeli and his followers contend that their presence is pathognomonic of pernicious anæmia. Their occurrence in other conditions has, however, been noted by various authorities. Piney[1] states that Ullman and Weiss recorded a case which in its early stages had all the characters of pernicious anæmia, but later became onverted into an equally typical case of acute eukæmic lymphadenosis.

Achlorhydria does not appear to have been recorded n the study of previous published cases of acute mphatic leukæmia.

The blood films showed an abnormal frangibility f the lymphoblastic cells, characterised by the esence of numerous so-called basket, shadow, or mudged cells; there were also present numerous ieder cells or binucleate lymphoblasts.

POST-MORTEM EXAMINATION.

Only a partial examination was permitted, and this was rformed on Jan. 25th, about three hours after death. Atten- n was directed to what were considered the most important gans. The abdomen was opened, and it was noted that e liver was slightly enlarged, pale in colour, firm in nsistency, with sharp edges, and that it bled freely on ision; the whole liver was not removed but a small slice s taken for examination. No enlarged lymphatic glands re felt on palpation in the abdominal cavity. The spleen s removed entire and was slightly enlarged, weighing g. The substance of the spleen was moderately soft, wing bright red points on a pinkish background. The kidney was removed, was of about normal size and was bedded in a large quantity of perirenal fat of a dead ite colour. It was smooth, showed slight persistence of al lobulations and was of a uniformly pale colour.

The thoracic cavity was not opened. The only palpable perficial gland, a small oval one about the size of a haricot an, was removed from the left inguinal region. The head the tibia was trephined and an attempt was made to tain a sample of the bone-marrow; this marrow was mpletely fluid, of a pale colour, showing a few red streaks, d was of about the consistency of cream. Even scraping th a Volkmann's spoon produced only a greasy fluid which mediately spread out, forming a scum, on the surface the fixing fluid. A portion of a rib was excised; marrow appeared normal to the naked eye. Smears were ade from the splenic pulp and from the tibial and rib arrow.

EXAMINATION OF FILM PREPARATIONS OF ORGANS.

Bone-marrow of tibia: Films stained with the greatest fficulty owing to their greasy nature. After treatment ith ether and alcohol, only a few scattered patches with llular content could be made out. These areas consisted artly of normal and megalocytic red blood corpuscles one megaloblast was seen), and partly of cells closely resembling the lymphoblastic cells found in the peripheral blood; nly one myelocyte was noted and no polymorphonuclear ells.

Bone-marrow of rib: The cells closely resembled lymphoblasts. No polymorphonuclear cells were seen.

Spleen smears: Besides showing a number of red blood corpuscles and a few large pigment-containing cells, the bulk of the cells seen were of lymphoblastic type.

In all the film preparations, other than those of the blood, the cells were almost devoid of cytoplasm, were distorted, stained indifferently, and were unsuitable for careful cytological study.

EXAMINATION OF SECTIONS.

Lymphatic gland: The architecture of the gland was moderately well preserved. The lymph follicles were intact, and, regarded as a whole, there was no germinal-centre proliferation. The sinuses and the pulp of the gland contained a greater number than normal of large cells of lymphocyte type. The impression conveyed was that the gland, acting, as it were, as a net, had caught up in its meshes numerous lymphoblastic cells.

Spleen: The malpighian corpuscles were in evidence but were not unduly prominent, nor were they increased in size. Their small cells stood out rather clearly in contrast to the larger cells packing the splenic pulp. Careful examination of the cells contained in the trabecular vessels and of those in the pulp showed them to be identical in appearance and of lymphoblastic type.

Kidney: No collections of lymphoblasts were seen in the kidney. A few were, however, present in the renal capillaries.

Bone-marrow of rib: The cells contained in the marrow spaces were almost entirely of the large lymphocyte type.

Liver: The liver cells in general showed a slight fatty infiltration and a considerable deposit of pigment. The most striking features were collections around the portal areas of lymphoblastic cells, and a subcapsular zone of considerable depth containing many of the same cells. These cells in the portal areas and subcapsular zone were identical with the cells contained in the portal vessels, and were morphologically lymphoblasts. Numbers of these lymphoblasts in the portal areas showed mitotic figures. This particular distribution of lymphocytic cells is very characteristic of lymphatic leukæmia (lymphadenosis).

As only a partial post-mortem examination was possible in this case it is useless to speculate as to the site of origin of the over-production of the lymphoblasts, but in this connexion it is interesting to note the mitoses in the periportal cellular collections.

Leishman's and Giemsa's stains were used for the study of the blood films, and hæmatoxylin and eosin for the paraffin sections. The oxydase reaction was done with hydrogen peroxide and benzidine. We are, of course, aware that it is by many observers considered impossible to distinguish between the lymphoblast and the early myeloblast, but we believe that we were dealing with a case of lymphatic leukæmia for the reasons already stated.

CALCIUM THERAPY AND THE TOXÆMIAS OF PREGNANCY.

By W. C. W. Nixon, F.R.C.S. Eng.,
LATE OBSTETRIC RESIDENT, QUEEN CHARLOTTE'S MATERNITY HOSPITAL.

Any means at our disposal to reduce maternal mortality must be exploited; and next to septicæmia, eclampsia is the most potent factor in the production of this mortality. A plethora of investigations have been undertaken, particularly on the biochemical aspect of this disease. This has emphasised the importance of calcium.

Calcium, we know, has an intimate relation to nervous sensitivity; this is shown by the increased excitability of nervous tissue on diminishing the calcium content of the solution which permeates it. Since tetany and uræmic twitchings are associated with a hypocalcæmia,[1] the convulsions of eclampsia might be attributed to a similar disturbance of the calcium content of the serum. A number of authorities have found a progressive lowering of the serum calcium in the latter months of pregnancy. Although there are only about 0·5 g. of calcium in the whole maternal blood stream, we know that the fœtus drains off as much as 8 g. for its own uses.[2] However, there is great difficulty in perfecting a correct technique of calcium estimation. One is, therefore, inclined to suggest that some of the results of the above workers are due to errors of technique. Actually, I always estimated the calcium of a normal blood with every batch of abnormal specimens. This showed the necessity of vigorous centrifugalisation and absolute freedom from hæmolysis. The results obtained are otherwise ridiculously low.

---

[3] Brodribb, A. W., and Lazarus-Barlow, P.: THE LANCET, 1931, i., 347.

Nevertheless, it is tempting to correlate, if possible, these three groups of phenomena—the convulsions of hypocalcæmia, the fœtal drain of calcium from the mother, and the convulsions of eclampsia.

Minot has produced in dogs a condition very similar to eclampsia.[3] By giving carbon tetrachloride to animals fed on lean meat he has induced convulsions. With the intravenous administration of calcium chloride, the dogs have recovered 30 minutes after the injection.

TRIAL OF CALCIUM.

During the months January to March of this year there were admitted to Queen Charlotte's Hospital two cases of eclampsia, eight of pre-eclampsia, and one of hyperemesis gravidarum. The serum calcium was estimated in all these cases by means of the Kramer and Tisdall method. Estimations were made in duplicate, and the normal value of serum calcium was taken as 9 to 11 mg. per 100 c.cm. of serum. In only one case—an eclampsia—was the serum calcium below 9 mg. The readings were as follows :—

	Per 100 c.cm serum.		Per 100 c.cm. serum.
Eclampsia	8·5 mg.	Pre-eclamptic toxæmia } ..	9·1 mg.
"	11·3 "	" ..	10·1 "
Pre-eclamptic toxæmia } ..	11·69 "	" ..	9·8 "
" ..	9·3 "	" ..	9·8 "
" ..	9·09 "	Hyperemesis gravidarum } ..	9·3 "
" ..	9·5 "		

In the hope of ameliorating the fits in eclampsia, calcium, in the form of calcium gluconate (10 c.cm. of 10 per cent. solution), was administered intravenously in the above two cases. These will be considered in detail.

CASE 1.—Primigravida, aged 27. Systolic blood pressure, 170. Patient drowsy, slight œdema of legs. Urine solid, with albumin. Three fits before admission. Serum calcium, 8·5 mg. One fit two hours after calcium injection. Serum calcium ten hours later, 10·5 mg. Delivery took place 33 hours after admission. The patient was discharged three weeks later. Serum calcium, 9·6 mg.

CASE 2.—Primigravida, aged 25. Slight œdema of legs. Blood pressure, 180. Urine solid, with albumin. Mentally dull. The first fit occurred during the withdrawal of blood for serum calcium estimation, which reading was 11·3 mg. Following the intravenous injection of calcium four fits occurred during the space of 15 hours, within which time the patient had been delivered. The serum calcium at the end of this period was 13·0 mg. There were three more fits, making a total of eight. Twenty-six days after delivery the serum calcium was 10·8 mg. Renal efficiency tests pointed to impaired function of the kidney (blood-urea—53 mg. per 100 c.cm. ; urea concentration, first hour, 0·8 per cent. ; second hour, 0·8 per cent. ; third hour, 0·8 per cent.).

It will be seen that in the first case there was a definite hypocalcæmia, and, notwithstanding the administration of calcium, one fit occurred. In the second case there was a marked hypercalcæmia, and still the fits persisted. The criticism might be made that the convulsions were maintained by the excessive calcium content of the serum. However, it has been shown experimentally in dogs that there are no ill effects until the serum calcium reaches 14 to 15 mg., when the predominating features are dullness, loss of appetite, atonia, and dehydration.

CONCLUSIONS.

(1) In pregnancy toxæmia there is little deviation from the normal value of serum calcium. (2) In eclampsia there may be fairly wide variations ; in the one case there was a slight hypocalcæmia, in the other definite hypercalcæmia (artificially produced). Calcium therapy in eclampsia is disappointing, and it would appear that the fits are not influenced by the calcium content of the serum.

I am indebted to the staff of Queen Charlotte's Hospital for allowing me to utilise their cases.

CLINICAL AND LABORATORY NOTES

A CASE OF CANCER OF THE BREAST

TREATED WITH RADIUM AND X RAYS.

BY S. GILBERT SCOTT, M.R.C.S. ENG., D.M.R. & E.,
CONSULTING RADIOLOGIST TO THE LONDON HOSPITAL.

THE following case possesses several features of technical interest.

A woman, aged 40, experienced pain in the right breast. A growth, evidently carcinomatous, about the size of a tangerine orange, was found under the nipple, which was retracted but otherwise normal. There was no discharge, nor was the skin involved. One enlarged gland could be felt in the supraclavicular fossa. A complete radiological examination demonstrated small metastases in the thorax. Further investigation disclosed a large tumour occupying the pelvis ; this proved to be a fibroid about the size of a six-months' pregnant uterus. The surgical removal of the breast—a complete Halsted operation—together with a dissection of the glands in the supraclavicular fossa and removal of the fibroid was considered. It was clear, however, that removal of the breast would have no influence on the thoracic metastases. Consequently, removal of the fibroid would benefit the patient but little and finally there was the doubt as to whether the patient would stand the strain of the double major operation.

The final decision was to implant radium needles under the growth in the breast and glands in the supraclavicular fossa ; to follow this up, as soon as possible, by X radiation—using the "saturation" technique for the destruction of the metastases. The large radiation field used in this method would at the same time include the uterine fibroid. Radium needles were inserted under the growth and glands by the surgeon, and the first saturation dose was administered on the tenth day after the insertion of the needles. At this period considerable local reaction was present, the breast being erythematous and painful, and there was slight sloughing of the skin towards the axilla.

Some workers state that radium and X rays should not be mixed ; in other words, X rays should not be used while radium reaction is still apparent. In this case, however, I decided otherwise, so included the breast in the radiation field, which covered the whole thorax. The immediate effect was a rapid clearing up of the sloughing, while certainly no ill-effects were noticeable.

The trunk was divided into two radiation fields, thoracic and abdominal, and the dose brought up to the point inducing slight nausea. The fibroid, of course, was included in the abdominal field. Without any undue disturbance the breast returned to its normal consistence, although the nipple is still slightly contracted. The glands in the supraclavicular fossa are not palpable, and the opacities previously seen in the thorax are no longer apparent, while the fibroid has shrunk to the size of a cricket-ball.

The saturation method is the utilisation of X rays of the medium wave length with light filtration, and has for its object the absorption of a large number of heterogeneous rays. By this method the dose can be administered over a large area without danger or severe constitutional disturbance of the patient—an important point in patients with malignant disease. It is only in this way that we can expect to influence, by direct and indirect means, these malignant cells that have got astray and are distributed throughout the body in unknown positions, eventually forming metastases.

I find the short wave or intensive radiation technique, whether by radium or X rays, not applicable in prophylaxis, for the essential feature of this method is the *local* delivery of a large quantity of *homogeneous* rays, calculated to deliver a certain dose at a pre-arranged depth.

The statistical tables of Portmann, Forssell, and others clearly indicate that the heavy homogeneous radiation should be avoided in prophylactic work. In fact, I think Béclère is probably correct when he states that this technique should be prohibited in these cases.

Pfahler suggested the saturation method some years ago, and with one important modification—namely, the use of a lower scale of wave length—the results without doubt are superior to the heavy radiation method, and to my mind it is the only logical way to radiate with the object of prophylaxis.

A CASE OF IMPENDING VOLKMANN'S ISCHÆMIC CONTRACTURE

TREATED BY INCISION OF THE DEEP FASCIA.

By C. W. Flemming, M.Ch. Oxf., F.R.C.S. Eng.,
SURGICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL.

The treatment of impending Volkmann's ischæmic contracture by free incision of the deep fascia over the antecubital fossa is a well-established procedure. Murphy, in an address which he gave before the American Medical Association in 1914 on the subject of ischæmic contractures,[1] stated that this method of prophylactic treatment should be adopted if removal of bandages and suspension of the arm have failed. Sir Robert Jones[2] referred to the method again in the opening address to the Orthopædic Section of the British Medical Association in 1928. But these and other references[3 4 5 6] to this operation do not give any detailed case reports. Two cases have been recorded in which an open reduction of a supracondylar fracture was performed owing to signs of impending contracture, and I have myself seen another. In the case reported here, incision of the deep fascia only was performed, the fracture remaining unreduced.

A boy, aged 10, was admitted to University College Hospital with a supracondylar fracture of his left humerus, about five hours after the accident. There was a considerable amount of swelling in the region of the elbow-joint; the radial pulse was fairly easily felt, though weaker than that at the opposite wrist. An immediate attempt was made to reduce the fracture. It was not found possible to flex the elbow without obliterating the pulse, and the arm was laid on a pillow in full extension. The next morning, 18 hours after the accident, the pulse was still palpable; a radiogram showed that the deformity had not been corrected. A second attempt, also unsuccessful, was made to manipulate the fragments into position. After this the radial pulse was no longer palpable, but the boy felt no pain in his forearm; repeated observations were made on his finger and wrist movements to make sure that there was no diminution in the activity of the flexor muscles. Forty-eight hours after the accident there was still no pulsation at the wrist, and he began to complain of pain in all his fingers. It was thereupon decided to operate.

A longitudinal incision was made in the middle line over the antecubital fossa, extending two inches up the arm and down the forearm. The subcutaneous tissues were infiltrated with blood; the superficial veins were much engorged. The deep fascia, when incised, split apart about three-quarters of an inch, and the muscles bulged into the gap. The muscle bellies were very pale, but there was no infiltration of blood into them. The wound was left open, and the arm was put on a pillow in a position of nearly full extension.

The next day the radial pulse was still impalpable, and pain and a sensation of pins and needles were still present, but there was a full range of movements of the fingers and wrist muscles. The pulse was first felt 24 hours after the operation, and thereafter gradually became stronger in volume; the sensation of pins and needles gradually diminished, but did not finally disappear until nine days after operation. The wound was sutured five days after the incision. A week later (and a fortnight after the accident) a Kirschner wire was inserted through the olecranon, and traction applied. The deformity was partially, but not wholly, corrected; callus was already visible in the radiogram. Had the wire been inserted at the same time as the incision over the antecubital fossa was made the deformity might have been fully corrected, as the fragment was then still mobile.

The range of movements at the elbow now, nine months after the accident, is: flexion to 90°, extension full. There is no limitation of pronation and supination, and no pain.

SCURVY FOLLOWING AN ULCER DIET.

By H. E. Martin, M.Sc., M.D. Manch.,
ASSISTANT MEDICAL OFFICER, WITHINGTON HOSPITAL, MANCHESTER.

An instance of severe scurvy in a patient under dietetic and alkaline treatment for duodenal ulcer has recently been under my care, and is of considerable interest.

Relatively few cases of this type have been reported. Davidson[1] describes three cases of deficiency disease in patients on an ulcer diet. The disease was characterised by spongy gums, purpura, dental caries, and intramuscular hæmatomata. Mettier, Minot, and Townsend[2] have reported eight cases of scurvy, two of which occurred in patients on special diet. One woman with gastric ulcer developed scurvy after seven years upon a cracker and milk diet. The other was a man who, owing to diarrhœa, was dieted exclusively upon boiled milk, flour, and biscuits. A month later he suffered from acute bronchitis, and this precipitated a mild attack of scurvy, which speedily cleared up when a more liberal diet was allowed. Immermann[3] describes a case of scurvy in a patient with colitis, whose diet had for 11 months been restricted to rice, milk, eggs, white meats, and broth.

A blacksmith, aged 27, was admitted to a general hospital in October, 1930, with a perforated duodenal ulcer which was sutured under spinal anæsthesia. After a rapid recovery, he was discharged about the middle of November, and advised to take a magnesia mixture before, and alkaline powders after, meals, and to adhere to the following diet:—

Breakfast: tea, and bread and milk with egg, or shredded wheat with milk, or Quaker oats with milk and sugar. Lunch: Madeira cake. Dinner: rice pudding, brown or white bread and butter, madeira cake. (Once a week, steamed white fish.) Tea: two boiled eggs, milk, bread and butter, cake, tea. Sometimes custard, or fish, or jelly.

From November, 1930, until his admission to the Withington Hospital at the end of May, 1931, he rigorously confined himself to this diet. In January, 1931, he was away from work two weeks with influenza, and on recovery he developed pains in the shoulders resembling rheumatism. The pains came and went, were not affected by weather, and when tension was placed upon the joints they became so severe that the patient was unable to move for some minutes afterwards. The ribs were very tender, and hurt when the patient breathed, or pressed upon them. In April the pain shifted from the shoulders to the lumbar region. The gums became swollen and dark, and bled when touched. There was complete loss of hair from the arms, legs, and axillæ; and the hair of the head came out in handfuls. The pain then moved into the thighs, and was so intense that the patient could not stand up straight, and had great difficulty in walking.

On May 20th he was admitted to Withington Hospital. He was then desperately ill. The gums were bluish-white in colour, spongy, and swollen, and bled on the slightest touch. There was a purpuric rash across the back of the shoulders. The petechiæ were raised, hard, and varied up to the size of a split pea. Both popliteal spaces were swollen up with intramuscular hæmatomata, the bluish colour spreading half way down the calf muscles. The knees were flexed, and could not be straightened. The patient was scarcely able to stand, and complained of a sense of tightness of the muscles of the thigh. The blood count was as follows:—

Red cells ..	5,200,000	Polymorphs.	60·2 %
White cells ..	4,600	Lymphocytes	28·2 %
Hb	94 %	Large mononucl. ..	9·0 %
Colour-index ..	0·90	Eosinophil.	2·0 %
		Basophil.	0·5 %

Slight anisocytosis was seen. Platelets were scanty.

He was prescribed a diet which included 4 lemons, 8 oz. green vegetables, 8 oz. potatoes daily, and an occasional grape fruit. Within ten days he was feeling perfectly normal and fit, and was able to walk. The only remaining evidences of the disease were slight yellowish staining behind the knees, and numerous small brownish blotches on the back, marking the site of the purpuric rash. He was then recommended to continue on diet rich in green vegetables, but from which the acid lemons and grape fruit were excluded.

For four months this patient had been treated as a case of rheumatism; later he had been diagnosed as a case of arthritis with pyorrhœa, and total extraction of the teeth had been recommended. Finally, he had been considered to be suffering from rheumatism with purpura, a course of salicylate baths and massage being prescribed. In view of the obscurity of the early symptoms, it seems probable that slight undiagnosed cases of this type are not uncommon.

Since Mettier, Minot and Townsend consider that the onset of the disease is often precipitated by a febrile infection, it is interesting to notice that in this case an attack of influenza heralded the onset of the scurvy.

LIBRARIES AND HOSPITALS.—Hampstead Public Library has arranged to supply the non-infectious wards of the local hospitals with books from its reserve stock.

SOUTHAMPTON FREE EYE HOSPITAL.—The Bishop of Southampton last week dedicated a new out-patients' department of this hospital, which has cost about £5000. The number of patients, the majority of whom are out-patients, rose from under 6000 in 1920 to 8421 in 1930.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

SECTION OF MEDICINE.

AT the third meeting of this Section the chair was taken by Dr. E. BOSDIN LEECH, Vice-President, and a discussion on

Toxic Goitre, its Course and Treatment,

was opened by Prof. F. R. FRASER. He said that the three lines along which conceptions of this disease had been altered in recent years were: (1) the correlation of the morbid anatomy of the thyroid with the clinical conditions; (2) the therapeutic use of iodine; and (3) the development of surgical treatment. The varying symptomatology of the disease could partially, though not wholly, be accounted for by variations in the strength of the stimulus, in the capacity of the thyroid to react, and in the state of the organs of the patient. In the elderly a moderate degree of intoxication would produce auricular fibrillation where in a young girl it would only produce a tachycardia. In the same way the vaso-motor system, digestive and excretory organs, and higher cortical functions were far more profoundly disturbed in the elderly.

Iodine reduced the thyrotoxicosis and—together with rest and other measures—brought the patient to an optimum condition for operation in a time that might be much longer than the ten days stated in the literature. When operation was unnecessary iodine was one of the most valuable methods of treatment available. It modified but could not prevent relapses. In fact, it did not reach the cause of the disease but merely altered its effects.

As a result of previous experience he had come to the conclusion that surgical treatment was indicated for patients with nodular goitres and for those who did not improve rapidly, became chronically ill, relapsed, or could not submit to adequate observation and treatment. In the quinquennium 1926–30 he had had 136 patients surgically and 64 patients medically treated. He had classed the results under four heads: good, poor, bad, and dead. Of the surgical cases 44 were good, 20 poor, 2 bad, and [illegible] dead; of the medical 23 were good, 15 poor, 3 bad, and 23 dead. Even when allowance was made for future improvement, the high proportion of poor results to good results in the surgical group was noticeable. The proportion of poor results increased with the age of the patient and with the duration of the disease. It was not always realised that the longer the thyroid intoxication continued, even if it was mild in degree and interrupted by numerous remissions, the less likely was the patient to be restored to health. In considering prognosis, ætiology must be taken into account. If the causal factor could be removed and the patient brought under early care, there seemed to be a possibility of recovery without operation in mild cases. In ten of the medical cases with good results there had been marked improvement after tonsillectomy; they had all been mild cases associated with attacks of tonsillitis, with an average age of 29 and average duration of two and a half years. The longer the duration the more difficult it was to discover the causal factor. Since the discoverable factors were such as must be experienced by most people in the course of their lives, there must be a constitutional factor as well, and this factor might be inherited and inborn. It could not, however, be recognised in the absence of the disease. In some patients it seemed to be so strong that no other factor was necessary. The stronger the constitutional element the worse the prognosis, even after thyroidectomy. In some of the "poor" results the patients had given histories of nervousness and excitability all their lives, and seemed to have been below the normal standard of physical efficiency before the onset of toxic symptoms.

Analysis of the results showed that surgery was indicated in most cases severe enough to be admitted to the wards of a general hospital. It was safer to operate at the earliest suitable opportunity than to hope for spontaneous recovery. Some method of reducing the amount of functioning thyroid tissue was essential to save life and restore efficiency. X rays and radium required long courses of treatment, and were uncertain in their results, and operation was preferable, to save time and avoid relapse. The surgeon must be one with special experience of this work. For patients still able to work, treatment by X rays and radium could be begun as soon as the diagnosis was made, and should be accompanied by removal of the causal factor and by iodine medication to reduce the intoxication.

Dr. JOHN EASON pointed out that many patients in alarming or strange circumstances showed a thyroid response which fell short of grave disease. The mobilising function of the gland was in control and the storing function in abeyance for the time being; consequently the gland had to overwork, but the formation of an abnormal secretion was not proved. Among exciting causes he had found emotion and worry in 62 per cent. of cases, though many of the patients at first denied worry because very often the trouble was related to sex. In 20 per cent. the disease had followed very soon after infection by tonsillitis or influenza. The clinical features and histo-pathology naturally varied with the ætiology. There was also a factor of predisposition. Certain endemic conditions, toxæmia, and long strains might predispose the gland to over-response. In the child the development of the autonomic system was inadequate for a response comparable to that known in exophthalmic goitre, but the seeds might be sown in childhood, moulding the active, slender type which resembled the frog produced by feeding tadpoles on thyroid. The female was predisposed by her specific endocrines.

The treatment was primarily medical, though the mortality-rate from operation was not really very high in the hands of an experienced surgeon. Indications for the use of iodine were given by the reaction of the morning and evening pulse-rate and respiration to small doses of potassium iodide. If the swing was flattened out the treatment was satisfactory. The effect of a single dose of grs. 4 of potassium iodide would last four or five days. Radium had produced marked improvement or cure in 24 out of 40 cases, and slight improvement in five more. The treatment only took one day in each two months. The results of medical treatment in Edinburgh were much better than those of Prof. Fraser, the mortality for the last three years being 3·9 per cent. They must refer to a much milder form of the disease.

DEEP X RAY THERAPY.

Dr. E. P. POULTON described the results of deep X ray therapy for toxic goitre. It was important to decide in advance on the line of treatment, as serious adhesions might be produced by deep X rays. Of 14 cases over a year in duration, 64·5 per cent. were able to do their former work and 28·5 per cent. were able to do light work. Similar results had been obtained in other cases not directly under his care. He asked, in view of these figures, why operate? The cases formed a representative series except that only two of them had had auricular fibrillation. The basal metabolism and pulse-rate had gradually fallen as the body-weight had gone up. He stressed the attacks of extreme muscular weakness associated with the disease. The test for it was to ask the patient to stand up on a chair, but many patients would relate that they had to pull themselves upstairs by the banisters.

Dr. W. L. WATT pointed out that the figures for deep X ray therapy compared favourably with the very best surgical results obtainable—those of the Mayo Clinic—and had no immediate mortality. Dr. Poulton's cases had all been treated with medium hard rays. Five cases with post-operative recurrence had shown marked improvement. A sarcoma dose of 80 per cent. was given, and its effect was, to all intents and purposes, a bloodless operation. In moderate cases one treatment was sufficient; in severe cases two were required. Milder cases would recover in two or three months; severe cases needed a year. In very grave cases the treatment was spread over five or six weeks. One case brought up in extremis, after influenza, had had five weekly treatments and had recovered completely. Relapses followed surgical treatment in a number of cases, and here a combination of surgery and X rays was of value.

PRE-OPERATIVE MEASURES.

Mr. JOHN MORLEY pleaded for a rational, carefully thought-out plan of campaign by the doctor in charge of the case. The disease could only be cured by subtotal thyroidectomy or X ray or radium treatment. If X ray therapy was to be safe it must show its effects in a reasonably short time. The milder primary cases should have a trial course, rigidly controlled, for three months. If the results were promising the treatment should continue; if not, the more rapid methods of surgery were the treatment of choice. Rather over one-third of the cases he operated on were X ray failures. The surgeon could promise a cure if the case was not seen too late. The operative risk could be reduced to a minimum by preparatory measures, chiefly the administration of iodine. The first iodine remission was usually the best, and should be the time of operation. Patients should not be put on iodine indiscriminately for several months; it should be held in reserve if there was any likelihood of operation. The next most important preparatory measure was digitalis in heroic doses for cases with auricular fibrillation. There must be an adequate period of physical and mental rest before operation. The diet should be rich in carbohydrates. Every surgeon had his own methods, but Mr. Morley preferred local infiltration anæsthesia for anxious cases, preceded by omnopon and scopolamine in carefully regulated dosage. He had found novocaine and adrenalin safe and efficient. Gas and oxygen must always be available in case local anæsthesia did not suffice. Ether and chloroform were dangerous. Nothing short of subtotal thyroidectomy was curative. The great thing was not to postpone operation so long that irreparable damage was done to the heart muscle.

Mr. W. H. C. ROMANIS declared that the term "toxic goitre" should not be applied to nervous patients with goitres and mild degrees of thyroid toxæmia. He required at least some detectable changes in the eyes and heart. A certain shininess of the cornea and some dilatation of the [illegible] were the earliest signs. In the "primary" of the disease was more severe and rapid; the "secondary" type was less severe, and the disease seemed to pick out the cardiac system as its main object of attack. These cases were very common among school-teachers and nurses. Medical treatment was chiefly valuable in preparation for operation. Radium applicators occasionally produced marked improvement, but both radium and X rays were notably uncertain. In the majority of cases operation gave the best, quickest, and most certain end-results, but many mild cases did not require it, and a few were too severe for it. The only cases definitely too bad for surgery were those with mental symptoms and intractable heart failure. Auricular fibrillation was not a contra-indication. Children should not be operated on until all other methods had failed. The operation should be early, and should be preceded by rest and iodine for 10–20 days. Thyroidectomy was the only reasonable operation, and the usual mistake was to remove too little tissue. Small isolated portions left might hypertrophy and cause recurrence. Local anæsthesia should be preceded by sedatives, preferably avertin. The mortality was about 3 per cent., and the great majority were greatly improved in the minimum of time. Patients should be warned that the exophthalmos would improve less than other symptoms, and that they must live an easy life for a few months after operation.

Mr. T. P. **Dunhill** emphasised the tragedy of the disease, and deprecated the tendency to say that operation was "safe" and "curative," which it was not. In the early stages the treatment should be medically controlled, but that did not mean that the best years of a woman's life should be wasted and operation never offered. He pleaded for earlier coöperation between physician and surgeon. X rays were good in some cases; others were not benefited, particularly very severe early cases and complicated cases. It was soon obvious whether the patient was improving. Operation in good time could send workers back to work and mothers back to their families before their organs were damaged and their capacity for work impaired. Operation should be done on cases with complications that could not be cured, provided the practitioner and patient realised the position. Operation was less crude a method than leaving patients to die or to live with ill-health. Children could not always be left safely; they sometimes died under medical treatment.

Colonel **Robert McCarrison** spoke of the malnutritional predisposing factor, and described experimental work on this subject. Hypertrophy and hyperplasia of the thyroid were most easily produced by feeding rabbits on cabbage; the metabolic-rate was not raised until iodine was added. A diet deficient in fat-soluble vitamin A produced a condition of depleted function of the thyroid cells, and the whole gland became flooded with lymphocytes (lymphadenoid goitre). Diet was very important in the treatment of Graves' disease, which was probably more a general disease than one localised to the thyroid. If the patient was going to utilise his carbohydrates, his diet must be balanced in vitamins and mineral salts.

Dr. J. O. **Summerhayes** spoke of the practitioner's difficulty in getting these nervous patients to go to hospital, and asked what was to be done for early cases by the family doctor.

Prof. **Rabinowitz** remarked on the rôle of the sympathetico-adrenal system in the production of this disease. The denervation of the adrenal medulla might play an important part in therapy. Two myasthenic cases had responded remarkably to ephedrine. Useful diagnostic features were the "scoop" nails, the warm, moist, tremulous hand, and the delicate skin—"the skin you love to touch." The nervous goitrous girl had a cold blue hand. Some of the worst cases were due to small nodules behind the sterno-clavicular junction. Bad cases should be treated surgically. Mild cases were best treated by arsenic, quinine, and luminal, and sometimes codeine, but he preferred surgery to radiation.

Dr. **Florence Stoney** suggested that in early and persistent cases the problem was to find what was irritating the gland: a source of focal sepsis, probably, or a fibroid condition of the uterus.

Prof. **Fraser**, in reply, summed up the agreed points: that a great deal of research was still required, particularly on the origin of the disease; that some means must be taken to reduce the amount of functioning gland tissue; that surgery was essential for urgent cases; and that radiation must be tried in the future for ambulant cases. He did not think that the use of iodine was limited to pre-operative cases and urged it in other circumstances.

SECTION OF SURGERY.

On July 23rd Mr. **R. Ogier Ward** opened the discussion on recent advances in

Diagnostic Methods in Renal Affections.

Mr. Ward paid tribute to Prof. von Lichtenberg who was responsible for the introduction of ascending pyelography, the method by which catheters were passed into the ureters from below, enabling opaque media to be introduced into the renal pelvis and calices. Instrumental pyelography needed care and practice, but given those conditions it was a safe and accurate method of examination and gave well-defined pictures. He pointed out that the radiograms obtained were of shadows and not of the actual objects, and the extreme accuracy obtained was the more satisfactory. Prof. von Lichtenberg was not only the inventor of instrumental pyelography but had been responsible for the development of excretion urography to its present high efficiency, thereby making a further and valued advance in the diagnostic method of renal affections. Several substances had been tried, but the most successful appeared to be D.40, now known as Uroselectan B. Mr. Ward showed a large number of radiograms which had been obtained during his own researches with this drug, and demonstrated its great superiority over its predecessors. Uroselectan B., he said, was introduced into the vein from the sealed ampoules in which it was supplied. Care had to be taken not to inject it outside the lumen of the vein, although no serious results from such an accident had been reported. None of his patients had experienced any untoward effects after the injection. Excretion urography could never replace ascending pyelography in the investigation of routine urological cases; it was an adjunct to this investigation, and only rarely did it supply information which could not have been obtained by other means.

One of the interesting results brought about by this new method of investigation was the fresh light shed upon the neuromuscular mechanism of the urinary tract; it would therefore be of assistance in the pathology and treatment of hydronephrosis, which disease was the result of a defect in the mechanism. A pyelogram clearly demonstrated a hydronephrosis; excretion urography sometimes showed the same hydronephrosis but of a considerably larger size. The reason for this discrepancy was that in excretion urography the kidney filled the pelvis at a rate to which it was accustomed, whereas in instrumental pyelography the opaque fluid had been forced through the ureteric catheter much more rapidly and the pelvis had resisted the process. This gave clear proof that the pelvic neuromuscular mechanism was not destroyed, though damaged, and was an encouragement to the surgeon who wished to perform a plastic operation.

The physiology of the pelvis and ureters in a normal subject, although perfectly demonstrated by the excretion of contrast media, required much study. It was easy to recognise obstruction because substances accumulated above it, but in health the drug was quickly swept along in the urine and the calices were not all filled at the same time. For this reason the shadows might be faint ones and were only apparent in first-class radiograms. The radiograms taken immediately after the injection should be studied with particular care, for later an accumulation of gas in the intestine might make interpretation difficult. Much further study was required, but it would not be long before further advances were made by means of serial and slow-motion cinema-radiography. Such processes ought to make clear the dynamics of the urinary tract in health and disease.

Mr. Ward showed radiograms of cases in which excretion urography had been of special value, since it was undesirable or impossible to pass the cystoscope. Such conditions obtained in the presence of urethral stricture, an enlarged prostate, or in severe cystitis. The passage of a ureteric catheter was not always possible or desirable in ureteric kinking, in urinary tuberculosis, and in the pyelitis of pregnancy. A striking example of its value in a case of ectopic kidney was demonstrated. Excretion urography should be regarded first and foremost as a means of studying the urinary tract as a whole, in a manner hitherto impossible. There was no need to claim that it had made standard methods of investigation of the urinary tract unnecessary; to these methods it should not be regarded as a rival but rather as a supremely valuable ally.

Dr. E. J. H. Roth emphasised the position of the radiologist in relationship to the urologist, and said that his importance rested on the fact that together with the pathologist he helped to form a urological unit. The apparatus now available had made a standard technique necessary. A good radiogram should not be a matter for congratulation, but an ordinary occurrence. The radiologist could never be a diagnostician, and a diagnosis founded on radiograms alone would be of little value and probably inaccurate. Mr. Roth described the technique of modern radiography in detail, and emphasised the modifications which were necessary in both ascending and descending pyelography. The shadows cast in descending pyelography were of such a nature as to demand the maximum radiographic contrast. He depicted and described a radiographic table designed for the new department of radiology at St. Peter's Hospital for Stone. It enabled radiograms to be obtained in the erect as well as in the more usual supine positions—a valuable factor in pyelography. The preparation of the patient for X ray examination of the urinary tract was described and its importance accentuated. Radiology offered valuable assistance in the diagnosis of lesions in the urinary tract. The patient might consider his renal pictures as the final word in the diagnosis of his condition; to the clinician, however, they must remain no more than aids to his own observation.

Mr. R. J. Willan showed radiograms obtained in a series of eight cases in which both ascending and descending pyelography had been carried out. In some of the cases a final diagnosis had been made, and the conclusions had been based upon the results of ascending pyelography; in others the descending method had carried weight in the final diagnosis. Descending pyelography was in its infancy, and much work would have to be done before confidence in its use could be assured. He also had no experience of ill-effects from the use of uroselectan, but he had always been very careful to obtain preliminary information about renal function; to this end he used the pheno-sulphonal dye and the salivary-blood-urea test.

Mr. K. Heritage showed a large number of films illustrating the value of descending pyelography in cases of renal tuberculosis. In his opinion the absence of shadow indicated that the patient had been insufficiently prepared, and a subsequent examination should be carried out.

Mr. J. F. Dobson thought that at first sight the pictures obtained might seem disappointing, but this was only if they were regarded as supplanting those obtained in ascending pyelography. The greatest value of this new method of investigation at present lay in connexion with renal tuberculosis, but it would not be long before descending pyelography became a routine accessory measure in all cases.

Mr. John Hunter said that he had noticed a general dilatation of the ureter in tuberculous cases investigated by means of descending pyelography, and asked whether this might be considered a diagnostic sign. He had seen no ill-effects in cases of deficient renal function investigated by the intravenous method.

Dr. E. W. M. H. Phillips reported the value of descending pyelography in a case of hydronephrosis.

Mr. A. H. Burgess made a plea for the adoption of the terms "ascending" and "descending" pyelography to describe the two methods. He pointed out that ascending pyelography was mechanical and not strictly anatomical in its distension of the pelvis and calices, whilst descending pyelography constituted a physiological process. He emphasised the value of negative results.

Dr. R. V. Hudson referred to a case of Dietl's crisis where no shadow had been seen during the examination shortly after the attack had occurred, but later a well-marked condition of hydronephrosis had become apparent.

Mr. C. A. Joll commented on the great degree of accuracy now obtained in modern urological surgery. He thought that the future of descending pyelography was assured, especially as a method of estimating renal function, and in very early cases of hydronephrosis.

REPLY.

Mr. Ward, in reply to questions, thought that the absence of shadow in apparently normal cases was due to rapidly functioning kidneys. He did not entirely accept the term "descending" pyelography, since the intravenous injection of the contrast medium enabled the observer to obtain an idea of the condition of the ureter and the bladder as well as of the kidney.

SECTION OF DISEASES OF CHILDREN.

On July 22nd the section discussed

Jaundice in Childhood.

The opening paper was read by Dr. A. C. Hampson, the President, Dr. H. C. Cameron being in the chair.

After briefly classifying jaundice on the basis of the anatomical lesion present in different types, Dr. Hampson emphasised the fact that age exerts an influence on the susceptibility to liver toxins; the child's liver is more susceptible than that of the adult, though it also shows a greater tendency to repair, and the liver of an infant shows maximal susceptibility.

JAUNDICE IN THE NEW-BORN.

He said that probably all infants at birth showed an excess of bilirubin in the blood. He had found an average concentration of 1 : 75,000, the normal in the adult being 1 : 1,000,000. In a case of "physiological jaundice," if death due to some other cause should occur, post-mortem examination showed staining of cartilage, of cerebro-spinal fluid, and of the nuclei of the brain, parts which are not stained in other forms of jaundice occurring in older patients. After birth there was a considerable amount of hæmolysis and a sharp rise in the amount of bilirubin in the blood up to the third or fourth day, and then a gradual decline. Before birth the fœtus has two possible methods of excretion of bilirubin, through its own liver and alimentary tract, or through the placenta into the mother's circulation. At birth the infant's liver must take on the whole work, and it might be some time before it was able to assume its full functions; this would afford an explanation of the presence of bile salts in the body fluids. Dr. Hampson's observations suggested that hæmolysis leading to "physiological jaundice" might be associated with a difference in acidity between red cells and plasma, such as he and M. Maizels had found in hæmolytic anæmias.

Icterus gravis neonatorum was similar in various respects to benign icterus neonatorum, but was almost invariably fatal if untreated. In this familial disease jaundice might be present at birth or appear within about 24 hours, and would rapidly deepen. The sequence of events was drowsiness, loss of weight, increasing anæmia, often hæmorrhages with bruising and convulsions, and death usually in coma within three weeks. The stools were normal in colour and liver and spleen were not usually enlarged. If in simple jaundice of the new-born there was delayed assumption of hepatic function, then a lesser competency on the part of the liver or an increased hæmolysis in icterus gravis might result in a fatal toxæmia. With a view to decreasing hæmolysis, Dr. Hampson had given human serum intramuscularly, 15 c.cm. daily for three or four days, with the remarkable result that 23 out of 24 cases made complete recoveries. He believed that cases with enlargement of the liver and spleen and pyrexia belonged to another group, and in such cases results had not been as good. He suggested trying mercury inunctions as well as serum in these cases. Jaundice in congenital obliteration of the bile-ducts usually appeared on the second day; meconium was usually passed, followed by pale stools; the liver was large and very hard and the spleen enlarged, and the infant often surprisingly fit till late in the disease; in the terminal stage hæmorrhages usually occurred and sometimes convulsions. Unlike Dr. Parkes Weber, he had found the cerebro-spinal fluid stained in some of these cases. The lesion was undoubtedly progressive, and the speaker favoured the theory that it was due to maternal toxins circulating through the fœtal liver and excreted into the bile-ducts. Though there was no evidence of the existence of syphilis in these cases, he had had results suggesting that mercury inunctions and serum injections might be beneficial also in this form of jaundice.

EPIDEMIC INFECTIVE JAUNDICE (CATARRHAL JAUNDICE).

Catarrhal jaundice occurred usually in epidemics or sporadically, but pandemics had been noted. The virus was so far unknown. One attack appeared to confer lasting immunity, the maximal incidence of infection being between five and ten years in children. The majority of the cases were observed in autumn. It was possible for the disease to occur in association with enlargement of the liver, but no jaundice; the essential lesion was a hepatitis. The duration of the disease was variable, and the liver might remain enlarged for weeks after all jaundice has disappeared. Occasionally cases suddenly took on grave characters and pursued the course of acute necrosis. Cases of catarrhal jaundice must be regarded as infectious, both before the jaundice had appeared and for some while after it had subsided. A running ear appeared to have been the source of infection in some cases. During epidemics the incubation period was usually 21 to 28 days. Dr. Hampson condemned the use of atophan for this condition. Where commencing cholæmia with necrosis of the liver was suspected he suggested the administration of intravenous glucose and insulin, and perhaps calcium gluconate.

Dr. J. C. **SPENCE** pointed out that epidemic jaundice in England was not due to the leptospira-icterohæmorrhagiæ. The infective agent was probably ultra-microscopic, and the usual incubation period perhaps four weeks. He described the development of the disease in a laboratory worker in whom the incubation period appeared to be five weeks. In the epidemics of so-called "camp jaundice," which he had seen in Gallipoli during the war, just as in the epidemic among the civil population in a part of Sweden in 1924–26, there were occasional cases of necrosis of the liver. In a recent small epidemic which he had been able to observe there were 19 cases of ordinary "catarrhal jaundice" and one fatal case of necrosis of the liver. Tests devised to estimate hepatic function in catarrhal jaundice gave variable results; but probably some of the normal results were due to the tests being carried out during the stage of recovery. In his view it was very important not to overtax liver function in this disease, but to feed the patient on easily assimilable carbohydrates. The symptoms of cholæmia should be more widely known, and Dr. Spence described the case of a boy of nine who showed restlessness, "cholæmic" wailing and shrieking, and nervous symptoms, including changes in reflexes and convulsions, characteristic of such cases. The association between jaundice and signs of derangement of the nervous system was of great interest. As Dr. Hampson had said, diplegia and other evidence of lesion of the nervous system might follow severe types of jaundice in the new-born, and the mental depression occurring with jaundice had had such wide recongition that it had even originated the word "melancholia."

LABORATORY TESTS.

Dr. W. W. **PAYNE** described the results of fragility tests for the red blood corpuscles in hypotonic saline, pointing out a very slight tendency to resist laking found in some cases of jaundice in childhood. The test had, of course, its chief use in the diagnosis of acholuric familial jaundice, but it must be remembered that the cells in this disease did not always show increased fragility, and that laking might occur within so-called normal limits. In doubtful cases the test should be repeated several times, and the result of the van den Bergh reaction taken into consideration. In none of his cases did the van den Bergh test yield normal results. As to liver function tests, he held that these gave little help in diagnosis, but might be of much value in the study of a disease; he had employed them in the study of asthma. In this disease, according to the lævulose test and the adrenalin test, liver function was not infrequently deranged.

The pathogenesis of

CONGENITAL ATRESIA OF THE BILE-DUCTS

was discussed by Dr. H. CHODAK GREGORY. She described the case of a premature infant with the symptoms of this disease. It died when about five weeks old; the liver showed no cirrhosis, and had scarcely any periportal bile-ducts, though bile capillaries were present and were gorged with bile and the extra-hepatic bile-ducts were patent. She believed that in this case the obstructive jaundice was due to a developmental failure of these periportal ducts, and suggested that the cirrhosis usually found post mortem might well be the result of the obstruction to the flow of bile. The known facts concerning the complicated development of the biliary system, and the occasional occurrence of other congenital abnormalities with atresia of the bile-ducts, favoured the view that the condition was in all cases a developmental anomaly.

DISCUSSION.

The PRESIDENT commented on the points of resemblance between the terror-stricken looks and screams of the child suffering from cholæmia, and the symptoms of the child with "night terrors." It was this resemblance which had first led him to employ glucose in the treatment of the latter condition, a treatment which certainly produced good results.

Among subsequent speakers, Dr. H. M. M. MACKAY mentioned the occurrence of types of jaundice in infants which it was difficult to classify under any of the accepted text-book heads. Dr. A. MONCRIEFF and Dr. C. F. HARRIS discussed the cause of hæmolysis of the blood and the consequent physiological jaundice in the new-born. Dr. E. H. RAINEY mentioned some of the contra-indications to operation, either in congenital obliteration of the bile-ducts, or in any case of persistent jaundice of the catarrhal type. Dr. E. GUNN described an epidemic of catarrhal jaundice in New Zealand, and Dr. J. HUTSON described the high incidence of physiological jaundice of the new-born in Barbados.

REVIEWS AND NOTICES OF BOOKS

Clinical Observations on the Surgical Pathology of Bone.

By DAVID M. GRIEG, M.B., C.M., F.R.C.S. Edin., F.R.S.E., Conservator of Museum, Royal College of Surgeons, Edinburgh; formerly Surgeon, Dundee Royal Infirmary. Edinburgh: Oliver and Boyd. 1931. Pp. 248. 30*s.*

Surgical Pathology of the Diseases of Bones.

By A. E. HERTZLER, M.D., Surgeon to the Agnes Hertzler Memorial Hospital, Halstead; Kansas Professor of Surgery, University of Kansas. London: J. B. Lippincott and Co. 1931. Pp. 270. 21*s.*

IT is an achievement for any author to retain the interest of his readers almost from cover to cover. Mr. Grieg certainly does this in his book, in which he sets out to simplify the conception of bone affections. Yet when we reflect on its contents we find ourselves inquiring in what respect light has been thrown upon osseous pathology. It is a book with one idea; much generalisation is done from the simple observation that hyperæmia often accompanies bone absorption, and that diminished blood-supply, when calcium is available, accompanies bone formation. There are no facts brought forward to support this hypothesis. Local concentration of calcium is postulated as necessary for bone formation, but the author provides no evidence that there is actually increase of calcium in the soft tissues in the vicinity of a fracture. He does not tell us of the possible part played by phosphatase, by glucose or the parathyroid glands. We read that the neck of a fractured femur when broken is absorbed because of increased blood-supply, that osseous union would occur when this dies down, were it not that "fibrinous exudation and the local excess of calcium is wasted by falling into the articular hæmosynovial effusion." The explanation of the formation of true bone in a laparotomy scar on page 15 is ingenious and full of interest, and is a good example of how the reader's attention is fixed and retained. On page 75 there is a fanciful explanation of the so-called expansion of bone. By decalcification the bone is said to become a softened tube, and inflammatory hyperæmia and exudation is held actually to distend it. The explanation of bony secondaries in sarcomata on page 240 is quite startling. The pictures of specimens of dried bones are extremely well executed, and the production of the book does credit to the publishers.

It cannot be said of Dr. Hertzler's book that it holds the interest of the reader. It purports to treat, in a comprehensive manner, the pathology of diseases of bone, and the author confesses that all his resources have been invoked in its compilation. It is the more to be regretted that the result is disappointing. The work provides but meagre information on quite common affections; for instance, rickets is dismissed in eight lines, whilst scurvy occupies but six. Achondroplasia, it is true, is a rare disease, and not of much surgical importance, but it would seem to deserve more than four lines, if worthy of mention at all. In the account of exostoses no reference is made to hereditary proclivity or to the views put forth by Sir Arthur Keith; while the recent work which has done so much to enlighten the pathology of osteitis fibrosa finds no place.

These random examples of defects have been cited in order to justify the criticism of this book as one which fails to reach the average standard of modern surgical literature.

The Mental Defective.

By RICHARD J. A. BERRY, M.D., F.R.C.S., F.R.S.E., and R. G. GORDON, M.D., D.Sc., F.R.C.P.E. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1931. Pp. 196. 8*s.* 6*d.*

IN a preface, the authors state that they have written this book in response to the demands of representatives both of the medical and lay public for a small popular work which would elucidate the growing problem of mental deficiency as seen in its legal, magisterial, social, and educational aspects. They have produced a readable and vigorous book, which, in under 200 pages, touches upon a wide range of subjects. In the compass of eight chapters, they discourse upon the evolution, anatomy, histology, and physiology of the central nervous system, the nature of instincts, the legal and medical approaches to the problem of defectiveness, the principles of heredity as applied to animals and man, the relationship of mental defect to other forms of illness, and the social consequences of mental deficiency. And in the last chapter they advance a remedial policy.

In their treatment of the subject from the medical aspect, the writers stress their belief that the essential characteristic of mental deficiency consists of a paucity of brain cells. This, they hold, reveals itself in a tendency towards microcephaly, observable in two-thirds of all mental defectives. In fact, such universality is attributed to this characteristic that they consider that "the time has surely come when 'microcephaly' as a 'type' of mental deficiency should disappear from medical text-books."

In approaching the question from the social aspect, a strong plea is made for an evaluation of mental deficiency in terms, not of scholastic educability, but of adaptability and social efficiency. The system of the self-supporting colony is advocated, not only for the four legally recognised categories of defectives, but also for a fifth group of "borderline normals" of a mental ratio of round about 70. For this group, a period of residence in a "therapeutic colony" is advocated. Here the doubtful case would, for a period, be retained under observation, with a view to determining his fitness for ultimate certification or eventual freedom.

Throughout the book emphasis is laid on heredity as the most important single and discoverable cause of mental deficiency, and control of immigration, more discriminating marriage laws, a quickened eugenic conscience, sexual segregation, and sterilisation are recommended as preventive measures.

The book contains much that will provoke dissent, and much that will arouse social and religious prejudices. It also runs counter to orthodox teaching on many points. It will probably commend itself to many who are dissatisfied with the sociological results of the methods of tackling the problem which have hitherto found favour, and will stimulate to fresh energy those who are convinced that these are on the right lines.

Étude clinique de la tuberculose infantile.

By JEAN LEVESQUE, Médecin des Hôpitaux de Paris. Paris: Masson et Cie. 1931. Pp. 150 and plates. Fr.22.

IN this small handbook the author has attempted a general survey of infantile tuberculosis in its clinical aspects. After a preliminary chapter on ætiology and pathological anatomy, he deals with primary infection and reinfection, and surveys, at some length, the well-known signs of infantile tuberculosis; he then goes on to discuss the modern methods of diagnosis, such as radiology and tuberculin testing. The last two sections are devoted to an exposition of the differential diagnosis and prognosis of infantile tuberculosis. The book closes with a small collection of well-reproduced radiograms.

The book is written in clear, interesting style, and, in spite of the fact that he has covered a very large amount of ground in the space of 150 pages, the author has succeeded in avoiding the errors of condensation which so frequently make this kind of book dull reading. Recent works, such as the Mantoux test with tuberculin and the researches of the French school of bacteriologists on the filterable virus in relation to heredity, are described, and the various modern treatments, such as ultra-violet rays, heliotherapy, B C G vaccine, are briefly touched upon. On this last point the writer is guarded in his views, and has managed to keep the question within the limits of a few short paragraphs. It is rather a pity that the brief statistics given towards the end of the book are not more recent, especially when there is such a wealth of material nowadays to choose from. A short, wisely selected bibliography, and a subject-index would have enhanced the value of the book considerably.

Prosthetic Dentistry.

By IRA GOODSELL NICHOLS, D.D.S., Lieutenant-Commander, Special Lecturer and Instructor in Dental Prosthesis, Dental Department, United States Naval Medical School. With many collaborators. London: Henry Kimpton. Pp. 687. With 830 illustrations. 50s.

DENTAL prosthesis more than any other branch of dentistry has become the battlefield of a large number of theories on occlusion and the movements of the condyles in mastication. Many highly elaborate instruments have been devised to imitate the condylar path; most of the theories are based on hypotheses which still require proof. Prosthetic dentistry has not received so much attention as other branches in the current literature on dentistry, although its practical importance is even greater than any other branch of operative dentistry. This volume, which is written by 45 dentists, illustrates both the merits and demerits of a composite work. Consisting as it does of a large number of sections, the reader loses the straightforward presentation of the subject which is possible when such a book is written by one man. On the other hand, few dentists can be equally knowledgeable in all branches of dental prosthesis, so that the work gains by the collaboration of a large number of experts. In this case we doubt if the gain compensates for the loss. The book is good in many respects; it is well written, beautifully illustrated, and, on the whole, clear; but it is a little disjointed. Dental prosthesis is essentially a practical subject. It calls for precise work, and needs craftsmanship. Such a subject requires to be methodically treated in sequence of the order of the work, so that the reader can readily follow the technique described. The various sections are good, but a certain lack of editorial control is apparent. Too much latitude has been given to the exponents of different methods, with the result that the reader is likely to be confused rather than edified. Moreover, so much space has been devoted to the more abstruse side of dental prosthesis that some of the more practical aspects are cursorily treated. Springs for the retention of complete dentures are no longer used to the extent common in the past, but they still have their place. Yet the only account of them given here is in the section devoted to restorations of deformities of the jaws following operation, and consists of but a few lines. The dentist desirous of learning the practical points involved in the fitting of springs in a full set of dentures would consult these pages in vain.

The book contains much that is of value, but it must not be regarded as a complete text-book of dental prosthesis. It is essentially one for the practitioner rather than for the student.

THE LANCET.

LONDON: SATURDAY, AUGUST 8, 1931.

ECONOMY IN THE SOCIAL SERVICES.

THE report[1] of the Committee on National Expenditure, appointed last March by Treasury minute with Sir GEORGE MAY as chairman, faces the disagreeable fact that public expenditure is too high and must be brought down to a lower level. The policy of retrenchment after the war was replaced in 1924 by a policy of expansion and development which added about 130 million pounds to our national expenditure as compared with that of seven years ago. Housing schemes, extended old-age pensions, beet sugar subsidy, widows' pensions, naval building programmes are only a few items in a long list. To the extent of about 20 million pounds a year we are now leaving posterity the cost of providing our own generation with these benefits. Future revenue is being mortgaged in spite of the practical certainty that by reason of the change in the age of our population the workers of the future will have to support a larger proportion of pensioners. The committee fears that the mass of the electorate does not appreciate the true economic position of the country, the struggle between expansion and retrenchment at election times always being heavily weighted by the better organisation of those who desire increased expenditure on particular objects.

Looking round for victims the Committee regards it inevitable that the chief opportunities of reduction should be found in the services of most rapid and recent growth. Although they attempt no definition of the category of social services, it is admitted that about 80 million pounds of the increased expenditure of the last seven years can be ascribed to their development, whether under government administration or control of local authorities. The majority report, signed by four members and the chairman, frankly gives the enormous increase in the exchequer charge for these services as the prime cause of the present financial crisis. Had it been possible to make sufficient reduction in other fields of expenditure they would gladly have been content with comparatively minor adjustments in this field. But after curtailing unemployment benefit, docking teachers' salaries, cutting down the road fund, and putting back army pay to the 1925 level, they are still obliged to suggest economies under the heading of national health insurance and of the maternity scheme which are peculiarly unwelcome to the profession of medicine. The lion's share of saving on the former is to come out of the pockets of the doctors, and the Committee is unanimous in suggesting a reduction of the capitation rate. Paragraph 409 runs as follows :—

> We are however of the opinion that the payments to the doctors are too high in present circumstances. These consist of a flat capitation allowance of 9*s.* per annum for every insured person in a doctor's list in addition to mileage allowances in rural areas, amounting in the aggregate to £250,000 and equivalent on the average over the whole of the medical panels to about 4½*d.* per insured person. It is common knowledge that the standard of remuneration of the medical profession has been greatly increased as a result of the Health Insurance Scheme and there has been growing difficulty in filling salaried medical posts under the Government and the local authorities at rates of pay corresponding to those in other classes of public service. In present circumstances we should not regard a reduction of the capitation rate to 8*s.* as unreasonable. This would represent a saving to the scheme of about £750,000 and enable it to meet the cost of central administration to this additional amount.

The suggestion of difficulty in filling salaried medical posts is, we find, a little belated. Like everything else the value of panel practices has been declining, and many recent appointments to government services have been filled by candidates who have disposed of practices with large panels because they have become less remunerative. The other economy suggested is the elimination of the grant of a quarter of a million pounds to the central fund which enables the less fortunate approved societies to pay their prescribed benefits, although an extended application of the principle of pooling of benefits is regarded as very desirable. The richer societies are in a position to maintain their additional benefits, and even to extend their scope, while other societies are in danger of being unable to maintain even the statutory rates of benefit. The chief factor in this difference is, in the Committee's view, not good or bad administration but differing health and unemployment risks of the members in the separate societies.

The maternity scheme is dismissed in the majority report as unduly ambitious in scope and containing the undesirable principle of differentiation between those who belong to the state insurance scheme and those who do not. The probable exchequer charge for this scheme of 1½ million pounds cannot be justified in the present financial circumstances. But to this economy the two Labour members of the Committee are dissentient, regarding the scheme as a bare minimum of requirement to meet the disturbing facts revealed in the departmental committee's report. They recall the fact that it was only in 1926 that the exchequer grants to insurance funds were reduced by a sum substantially larger than the annual additional charge necessary to provide these maternity services. As to health insurance the minority report agrees that provision should be made from within the insurance fund to maintain the statutory rates of benefit, if necessary by a direct levy on the disposable surpluses of societies. The two signatories possibly overlook the fact, made clear in the main report, that these surpluses are the property of the members, representing a reserve consisting of the excess value of the contributions made by each person in his early years over the benefits received by him. In the case of both majority and minority reports the proposals are made with frank regret that it is not possible to arrange for all classes of the community to suffer an all-round reduction of income. The majority report revolts from singling out public servants and pensioners from the rest of the community for special sacrifice; the minority report turns to an adjustment of taxation in relation to the uncovenanted benefits, now being received by the holders of fixed incomes, as a direction in which further hardship may be avoided to those least able to bear it.

---

THE MEANING OF "DENTAL SURGEON."

THE connotation of "dental surgeon" is presumably a question of fact. The question has just been answered by Mr. Justice Farwell in the Chancery Division. Leave to appeal against this important decision has been granted.[1] In order to appreciate the importance of the case it is necessary to remember that the titles "dentist" and "dental practitioner" are statutory descriptions. Provided that he is on the register, a dentist may use them whether or no he has a degree or diploma. There is a third description, "dental surgeon," which is not mentioned in the Dentists Acts, but is widely understood to imply the possession of degree or diploma. If this understanding is sufficiently well founded, any registered dentist who calls himself a "dental surgeon" without possessing a degree or diploma offends against Section 4 of the Act of 1921; he is using a title or description which, in the words of the section, is reasonably calculated to suggest that he possesses a professional status or qualification other than the professional status or qualification which he in fact possesses.

In the recent Chancery proceedings, the Attorney-General, on the relation of the British Dental Association, brought an action against a dentist practising at Norwich. The defendant possessed neither degree nor diploma. The Attorney-General asked for a declaration that the defendant's use of the title "dental surgeon" was reasonably calculated to suggest that he possessed a professional status or qualification which he did not in fact possess; he also asked for an injunction to restrain the defendant from using the title. The defendant pleaded that he was entitled to use the description. The plaintiffs called several witnesses practising as dentists in various parts of the country, who said that to them the title "dental surgeon" implied a decree or diploma; they had known "1878 dentists" who used it but no "1921 dentists" other than the defendant. The Secretary of the Incorporated Dental Society, and other witnesses for the defendant, said that all persons practising as dentists in industrial districts called themselves "dental surgeons"; if they had degrees they indicated the degrees on their signs. "Dental surgeon," they said, meant no more than dentist. Counsel for the defendant pointed to the use of the words "dentistry" and "dental surgery" in the 1878 Act as if they were synonymous. He argued that a man qualified to practise dental surgery might reasonably call himself a dental surgeon; the "1878 dentists" used the title "dental surgeon" though they had no degree. Mr. Justice Farwell granted the declaration and injunction in the terms of the application. He inferred from the evidence that to many people "dental surgeon" had a definite meaning and that to many it had none. He could not neglect the evidence for the plaintiffs. The question of the title of "dental surgeon," he said, had been a moot point before 1921; if the legislature had meant the title to be used by the newly registered class, it could have inserted the title in Section 4 of the 1921 Act, along with "dentist" and "dental practitioner."

Many who recall the genesis of the 1921 Act would deem it unfortunate indeed if this decision should be overruled on appeal. The need of proper care and treatment of the teeth is by no means fully realised by the public, though the lesson is being steadily spread. If the necessary recruits are to be attracted to the dentist's profession, it is a mistake to neglect or obscure the evidence of the student's training. The profession has had to fight for its standards. There has been a long struggle against the ingenious use of unjustified titles and descriptions. The Act of 1921 was not ungenerous to persons previously unregistered. Sir Norman Bennett had explained to the Acland Committee, whose report led to the passing of the Act, that many existing practitioners deemed it inequitable to take away their exclusive right to the title of "dentist" and to give that title to persons then not on the register. But it was hard to invent an alternative description. He realised, he said, that persons on the register must have some title or other, and he could suggest nothing but the dictionary word "dentist." Little mention was made to or by the Acland Committee of the description "dental surgeon." But, then as now, those who are in the best position to know have no doubt that the description has a special meaning. If it really has no meaning at all, perhaps there would be less inclination to usurp it.

THE RENAL LESIONS IN BRIGHT'S DISEASE.

BRIGHT'S method, his great legacy to medical science, was the explanation of disease by a reference to morbid anatomy. This is the ideal which the authors of an important monograph[1] recently published have set before themselves. It contains the results of a combined investigation by a physician, Prof. THOMAS ADDIS, and a pathologist, Prof. JEAN OLIVER, of 72 cases of Bright's disease, in an attempt to correlate the clinical manifestations of the disease with the structural alterations occurring in the kidney. Impressed, as many others have been, by the relative failure of the study of renal function to solve the problems of nephritis, the authors have eschewed all but the simplest functional tests and have relied for their diagnosis of the clinical condition of the patient on the case history, the physical examination, and the study of the urinary deposit. Prof. ADDIS has already shown how illuminating the study by an expert of the urinary deposit may be, and in the present work he constantly emphasises its importance. He insists that the clinical intuition which is so important in other branches of medical practice constantly fails when applied to the complex condition known as Bright's disease so that even masters of the art are frequently misled.

---

[1] A verbatim report of this important case will appear in the next issue of the British Dental Surgeon, the Journal of the British Dental Association.

[1] The Renal Lesions in Bright's Disease. By Thomas Addis, Professor of Medicine, Stanford University; and Jean Oliver, Professor of Pathology, Long Island College of Medicine; formerly Professor of Pathology, Stanford University. New York: Paul B. Hoeber. 1931. Pp. 686. 170 full-page plates. 21 text illustrations. $16.00.

> "They are misled because of the great variability of the manifestations of Bright's disease in the different tissues and organs of the body, so that it is seldom safe to deduce the state of the kidney from observations on the vascular, hæmopoietic, or nervous systems, or wise to form a judgment as to the predominant renal lesion even from the sum of all that by means of present clinical methods is seen, felt, or surmised. But, principally, they are misled because for many years they themselves have ceased to study the urine which comes from the diseased kidneys of their patients. They deal only with symbols transmitted to them by hurried and machine-like technicians, although within that urine which they never see is contained all the direct evidence as to the nature of the renal lesion."

Prof. ADDIS's method consists essentially in the determination of the functional capacity of the kidney, or the extent of the renal lesion by a comparison of the rate of urea excretion with the blood-urea concentration; and an estimation of the nature of the renal lesion by the amount of protein excreted and the examination of the urinary deposit. To be of value the urine examinations must be controlled and carried out by an expert. Inasmuch as protein, casts, and blood occur in the urine of healthy people, the diagnosis of Bright's disease becomes a quantitative one and rests upon the demonstration of larger quantities of protein and casts than occur within the range of normality. The need for accuracy in the investigations is, therefore, of the greatest importance, and this is especially so in the examination of the urinary deposit, for casts and cells vary in form and number with the concentration and reaction of the urine, and the red corpuscles which are the key to the situation may be so distorted as to escape recognition by anyone but an expert in this technique. Moreover, as Prof. ADDIS frankly says, the method has its limitations. The formed elements of the urine merely represent waste products of active lesions and give no indication of the important progressive or proliferative changes which may be taking place in the kidney.

The pathological side of the investigation, carried out by Prof. OLIVER, has been strictly limited to the examination of the diseased kidney itself, for the renal lesion in Bright's disease was the subject of the investigation, and, moreover, in many cases only the kidneys were available for study. Inasmuch as the clinician considered both the nature and the extent of the renal lesion, it might be expected that the pathologist would do the same, but, as Prof. OLIVER points out, such a procedure at the present time is practically impossible. A qualitative histological study is comparatively easy, but a quantitative estimation of the renal lesions expressed in terms of functional capacity is an entirely different matter. It is easy, for example, to distinguish an inflammatory process in a glomerulus, but we have no means of determining how its power to excrete water is affected thereby. Prof. OLIVER has, therefore, limited himself to an objective description of the lesions he has observed, but his valuable chapter on pathological definitions suggests that had he been content to follow a less austere method he could have wandered far in the realms of theory.

As the result of his observations Prof. ADDIS has arrived at the following classification of Bright's disease: hæmorrhagic Bright's disease, of which the initial, latent, active, and terminal stages can be recognised; degenerative Bright's disease, including the cryptic, pyogenic, non-bacterial, and bacterial forms; and arterio-sclerotic Bright's disease; and the cases are grouped under these headings. The history and relevant clinical details of each case are given at length, and there is a brief discription of the naked-eye appearances of the kidneys and a detailed report on their microscopic structure. But the feature of the case records are the illustrations—the structure of each kidney is illustrated by two photomicrographs, one of a magnification of 20, the other of 125, so that the reader is able to see for himself the actual lesion associated with the clinical condition described. There are 142 of these plates, and they are admirably reproduced—the lower magnifications are sometimes a little difficult, but with careful study they will be found to fulfil the purpose claimed for them. These plates are not illustrations in the ordinary sense of the term; they "were not chosen to elucidate the text, but rather the text supplements, in its insufficient way, the actual images, as near as may be, which we had before us in our study." There are, however, in addition, 26 high-power drawings of frankly selected specimens chosen to illustrate the text. The book is concluded by short chapters summarising and correlating the clinical and pathological data.

It would be almost impertinent to offer praise to such an admirable example of what can be achieved, without dogmatism or bias, to clarify one of the most complicated problems in medicine.

ORTHOPÆDIC HOSPITALS.—A new orthopædic hospital, to cost about £30,000, is to be erected in conjunction with the Royal Victoria Infirmary, Newcastle-on-Tyne. On the ground floor will be demonstration and lecture rooms, consulting rooms, a gymnasium, accommodation for hydrotherapy, a sunlight ward, a radiant heat ward, massage rooms, and dressing rooms. Wards for patients and accommodation for sisters will be on the first floor, the second floor will be given over to wards for the reception of women and children patients, and the third floor will include an operating theatre, plaster room, and store rooms. From each ward there will be access to sun balconies, and the flat roof will be used as a roof garden, for treatment of patients in the open air.—Mr. H. J. Alpass, M.P., recently opened a new out-patient department of Bristol Orthopædic Hospital to meet the demand for accommodation. Out-patient attendances have grown from 4137 in 1912 to 13,156 in 1930; in addition, there were 3305 attendances at the Bedminster branch. The work has cost £5500.

ANNOTATIONS

CLINICAL TRIALS OF NEW REMEDIES.

THE Medical Research Council announce that they have appointed a Therapeutic Trials Committee, as follows, to advise and assist them in arranging for properly controlled clinical tests of new products that seem likely, on experimental grounds, to have value in the treatment of disease :—

Prof. T. R. ELLIOTT, Physician to University College Hospital, London (Chairman).
Sir E. FARQUHAR BUZZARD, Regius Professor of Physic, University of Oxford.
Dr. H. H. DALE, Sec.R.S., Director, National Institute for Medical Research.
LORD DAWSON OF PENN, President, Royal College of Physicians, London.
Prof. A. W. M. ELLIS, Physician to the London Hospital.
Prof. F. R. FRASER, Physician to St. Bartholomew's Hospital, London.
Sir JOHN PARSONS, Ophthalmic Surgeon to University College Hospital, London.
Dr. J. A. RYLE, Physician to Guy's Hospital, London.
Sir JOHN W. THOMSON-WALKER, Consultant Urologist to King's College Hospital, London.
Mr. WILFRED TROTTER, Surgeon to University College Hospital, London.
Prof. D. P. D. WILKIE, Surgeon to the Royal Infirmary, Edinburgh.
Dr. F. H. K. GREEN (Secretary).

Conditions have been the subject of discussion and agreement between the Medical Research Council and the Association of British Chemical Manufacturers, under which the Therapeutic Trials Committee will be prepared to consider applications by commercial firms for the examination of new products, submitted with the available experimental evidence of their value, and appropriate clinical trials will be arranged in suitable cases. The Committee will work in close touch also with the existing Chemotherapy Committee, who are engaged for the Medical Research Council in promoting researches aimed at the discovery and production of new remedies.

The Therapeutic Trials Committee will invite suitable experts in particular branches of medicine or surgery to undertake the clinical tests of preparations accepted for trial. The reports of the results will be published under the authority of the Committee.

THE TRANSMISSION OF CHOLERA.

DURING the 50 years 1877–1927 there was no striking reduction in the recorded mortality from cholera in British India, and no decline in either the frequency or intensity of epidemics. Stricter and more energetic control has had to contend with improvement in transport and consequently wider spread of infection, and the mortality is still round about 300,000 per annum. This comparative failure has led Lieut.-Colonel C. A. Gill and Dr. R. B. Lal to undertake a detailed study of the epidemiology, and they have done so from a new aspect.[1] They started with a working hypothesis that the house-fly is a link in the chain of infection—not merely as a mechanical agent in the pollution of food and drink, but as a true biological carrier in which the cholera vibrio undergoes development. Dr. Lal, who was responsible for the laboratory work, found that the vibrio seemed to disappear from the body of the fly after 24 hours, only to reappear about the fifth day, when the fly was infective through its fæces. He and Colonel Gill are not yet convinced, however, that any part of the life cycle is passed in the fly, and their theory is so far only a theory, though an interesting one. The bulk of their paper is devoted to an account of cholera epidemics in the Punjab from 1924 to 1929. They distinguish two different types of outbreak—a "protracted" type, with slow onset and diffuse distribution, and an "explosive" type which is sudden, sharp, and circumscribed. The difference may be put down either to changes in virulence or to dissimilar modes of transmission. As a sidelight on native lack of sanitary sense, they mention a case where the clothing of a traveller, who died of cholera in a hitherto uninfected village, was washed in the well which provided the main water-supply, with the result that within 24 hours there were 180 cases with 16 deaths. Efficient control is inevitably difficult in circumstances like this, but Gill and Lal think that cholera is not permanently endemic in any part of the Punjab, and that imported cases from the United Provinces and Hardwar are mainly responsible for periodical outbreaks. Cases also arise from the Himalayan region, where cholera may persist throughout the winter and break out in epidemic proportions in the following spring. "Acute" carriers are, in their opinion, much more often responsible for outbreaks than "chronic" carriers. It appears that water-borne infection is comparatively rare in the Punjab; indeed, it is said to account for only 2·5 per cent. of all outbreaks. It is significant that no great fall in the cholera death-rate has followed the installation of piped-water suppliers. The investigators are convinced that the institution of an efficient collection and disposal system for night-soil is of prime importance in the control of the disease.

THE AGED HEART.

ALTHOUGH the expectation of life has been appreciably lengthened in recent years, most of this gain has been made by the decrease in infant mortality and it hardly affects the outlook in adult life. Since a large proportion of the deaths of older members of the population are certified as due to heart disease much interest attaches to F. A. Willius's investigation[1] of the heart in an unselected group of patients aged 75 or more. Although it is now generally considered that the normal blood pressure does not vary much from youth to old age, three-quarters of the 700 men and women studied had a systolic blood pressure of over 140 mm. of mercury; in only 10 per cent., however, was this over 200 mm. and in only 40 per cent. did the diastolic pressure exceed 90 mm. Further the majority of those with hypertension were in the younger age-groups (75–80). Hence one may say that while in old age a certain amount of hypertension is the rule, a normal blood pressure is favourable to still longer life. Fifty-five per cent. of the subjects showed clinical evidence of heart disease, and in almost all of them it was diagnosed as being either hypertensive or coronary in origin. The majority of those with signs of coronary disease suffered no anginal pain and in the whole series there was only one case of coronary thrombosis. This is in accord with other evidence that coronary thrombosis is commoner in younger people and suggests that those living beyond the normal span of life have coronary arteries with such a free anastomosis that arterio-sclerotic changes are comparatively easily compensated. The fact that only 12 per cent. of the whole group had congestive heart failure is further evidence that the heart that permits its possessor to live for more than 75 years is indeed an organ of peculiar quality.

INTERNATIONAL UNION AGAINST VENEREAL DISEASE.

REPRESENTATIVES of 44 countries, members of either a Government, or of venereal disease departments, or of voluntary organisations recognised by Governments, form, it may be known, the Union Internationale contre le Péril Vénérien, and this body has for the past year been reviewing the general position in civilised countries with regard to venereal disease. The scope of the various schemes is seen to vary considerably, the complete scheme adopted in our own country contrasting with the more limited endeavours to arrest the spread of syphilis only. There has been considerable controversy on the Continent as to the extent to which State funds ought to be expended in the treatment of venereal disease. Scandinavian countries, for example, advocate the taking over by the State of the treatment of the patient until cure can be considered complete—this in the interests of preventive medicine. Other countries hold that measures to ensure the immediate disinfection of patients is all that the State ought to be required to provide. Reports have now been presented to the Union Internationale by Profs. Bayet, Jeanselme, and Jadassohn, resuming the general principles of antivenereal campaigns from social and individual points of view, with the result that the Union has decided to ask Governments, public authorities, and antivenereal associations to bring certain cardinal conclusions before the medical profession in their respective countries. These conclusions are as follows: that the contagiousness of the patient must be reduced in duration by immediate and intensive treatment, to be continued until the chances of reappearance are removed; that congenital syphilis must be met by systematic inquiry into family circumstances as well as by examination of patients, treating not only congenitally diseased children but parents before procreation, and the mother during pregnancy. The soundness of the conclusions is obvious, and the British Social Hygiene Council has requested their publication by the medical press of this country, as a proof of the practical interest now manifested throughout Europe in the endeavours to avert a social menace.

ESCAPE FROM SUNK SUBMARINES.

THE catastrophe of the submarine *Poseidon* has drawn general attention to the possibilities of escape with the aid of a respiratory apparatus. The principle underlying the submarine respirators—of which there are many patterns—is that the chief danger to be avoided is rapid decompression, with resulting air embolism causing paralysis or death. At a recent meeting of the Academy of Medicine in Paris, Dr. Guglielminetti[1] made the interesting suggestion that complicated apparatus may not, after all, be necessary for escape from a submarine which has rapidly sunk as the result of collision. He admits that our knowledge of the physiology of life at great depths is still very inadequate, but takes as his text the pearl-diver of the Indies. He points out that there is no danger from emboli at depths of less than 13 metres, and that below this depth their formation depends on the length of time that the man has remained under pressure. He also lays stress on the fact that the nitrogen of the air embolus is derived from the air breathed in, and expresses the opinion that a period of five minutes is not sufficient to charge the blood with enough nitrogen for the formation of emboli. If, therefore, the sailor can reach the surface within five minutes of being subjected to increased atmospheric pressure he will not run the risks of decompression. Pearl-divers descend quite as far as many submarines, stay there just long enough to snatch oysters from the rocks, and return rapidly to the surface. They arrive exhausted and suffocated, but they never show the phenomena of decompression. The human body can stand extraordinary pressures, because it is composed of 90 per cent. of water, and if the dangers of decompression could be averted the occupants of the submarine could rise to the surface without apparatus, just like the pearl-diver. Survivors of submarines destroyed during the war declare that they shot to the surface with great rapidity, and Dr. Guglielminetti calls for laboratory experiment to find whether it is not really possible for men caught in disabled submarines to take a deep breath and then let themselves rise to the surface without any further complications.

IRON IN THE BLOOD OF INFANTS.

Dr. Helen Mackay's report[1] on the nutritional anæmia of infancy is to a certain extent supplemented by a careful study of the iron content of the blood of infants by Dr. I. A. Kotikoff[2] of Leningrad. His observations were made on a group of 20 normal breast-fed babies, beginning at the end of the second week in life and continuing first at fortnightly and later at monthly intervals. The blood was obtained from a small incision in the heel and the iron was estimated by the Foweather method, a total of 119 estimations being carried out altogether. The adult standard of 50 to 60 mg. per 100 c.cm. was accepted for purposes of comparison and on this basis the iron content of the infants' blood quickly fell from a high level in the first few weeks to a subnormal level which persisted for the rest of the first year. The average in the first month for 14 infants was 61·8 mg. per 100 c.cm. and the lowest figure recorded was in the ninth month when it dropped as low as 38·7 mg. According to Kotikoff, it may be taken that after the preliminary period of about six weeks, during which the organism is adjusting itself to new conditions, the iron content of the blood lies between 40 and 45 mg. This figure for iron shows a close connexion with the figure for hæmoglobin and it is demonstrated that the amount of hæmoglobin expressed in milligrammes per 100 c.cm. is 1·87 times the amount of iron. Kotikoff has tried to discover why healthy breast-fed infants should all have a comparatively low blood iron. He admits that breast milk does not contain an adequate amount of this substance, but all these children, from the sixth month, and sometimes earlier, received a mixed diet with fruit juice, vegetable soups, and the like. He finds that the beginning of this mixed diet causes a temporary slowing of the gradual fall of blood iron and he thinks that further work will be able to show the importance of dietetic factors. The iron content was apparently not increased by ultra-violet irradiation or by cod-liver oil. A definite rise was noticeable towards the end of spring and Kotikoff thought this could be correlated with certain weather conditions. Carrying his biochemical investigations a step further he estimated the calcium and potassium content of the blood in some of these infants and found a definite relationship between these and the amount of iron present. He says that in the first year of life the iron divided by the calcium gives a factor of 3·89 and if this figure falls below 3·5 it indicates a definite pathological state. By studying the amount of iron in the blood month by month in individual cases he shows that the amount present is a good criterion of the infant's health and in a few cases in his series sudden changes were observed in association with passing illnesses. He argues from his results that from the very early days of infancy it is necessary to supply iron to the organism and he pleads for more research to discover the best way of giving it. The work of Dr. Mackay supplies an answer.

DEVELOPMENTS AT HANWELL.

THE centenary of the Hanwell Mental Hospital was celebrated on July 29th by the opening of an admission hospital. As Dr. Adeline Roberts and other speakers pointed out, this hospital has, in the course of its history, been a pioneer in more than one direction. The name of Colonel Clitherow, the first chairman of the first visiting committee, is closely associated with the formation of the Queen Adelaide Fund, the first of after-care associations. The first superintendent was Dr. (afterwards Sir) William Ellis, a pioneer of "occupational therapy." He set the patients to trades and established a "bazaar," where the goods they made were sold, the proceeds being used for their benefit. As early as 1832 a consulting physician and a consulting surgeon were appointed. In 1839 the famous Dr. John Conolly became superintendent. He it was who abolished barbarous mechanical restraint, following the example of Pinel and Tuke. The hospital, originally built for 300 patients, now has 2400 beds, and during the war it actually accommodated 2750 patients at one time. Mr. L. G. Brock, the chairman of the Board of Control, in declaring the new admission hospital open, hailed the occasion as one of quite exceptional interest, because it combined a centenary—the triumph of antiquity—with the opening of an admission hospital, the triumph of modernity. He emphasised the fact that early treatment consisted both of earliness and of treatment, and deprecated the lip service paid by some people to the idea of early treatment by the provision simply of a place where the new admissions could be kept apart from the other patients. The real admission unit, the strategic centre of the whole organism, was a place where everything possible was done to alleviate the patient's condition and where he might find attractive and suitable environment. It was absolutely essential, he said, that the provision for early cases should be of a kind that would encourage them to apply for treatment, and that the treatment should be such that they would have faith that everything possible was being done for them. It was no use calling an institution a hospital unless it was permeated with the hospital spirit. He expressed his conviction that effort in this direction would be reflected in the recovery-rate, and cited the malarial treatment of general paralysis as sufficient answer to any pessimist.

The new villa is a detached, self-contained unit, to be staffed mainly by women nurses. It will provide accommodation for 50 men and 50 women, and is built mainly on one floor on three sides of a quadrangular courtyard. Each block has an examination room, a sick dormitory, a verandah, private rooms, and a solarium, and in the central block are kitchens and an association room common to both sexes. Special rooms for X rays, ultra-violet rays, and Plombières treatment are provided. The estimated cost of the villa, including its equipment and grounds, is over £53,000, and this building is the first item in a long programme of modernisation which the London County Council has decided to undertake in the oldest public mental hospital of the country.

HOUSING AND MALARIA.

A VALUABLE summary[1] prepared by Lieut.-Colonel Clayton Lane shows once more the importance of housing as a factor in the problem of malaria. It is well known that in areas where malaria is endemic certain houses acquire the reputation of being "malarious," from the fact that their inhabitants are frequently attacked by the disease, and the available evidence indicates that, in Europe at least, these houses have several characteristics in common. They possess rooms or landings which are dark, dirty, and often damp, qualities which appear to be attractive to malarial mosquitoes. The anopheles associated by experience with malaria are chiefly night-biting mosquitoes which attack their sleeping victims in their houses. The primitive house-dweller, it seems, often provides his own protection by building his house without a chimney, smoke being as offensive to mosquitoes as darkness is attractive; indeed, there appears to be reason to suppose that the invention of the chimney favoured the increase of malaria until a taste for larger windows came to balance it.

The suggestion that mosquitoes have an instinct to return to a pleasant hospice is only supported by questionable evidence, Colonel Clayton Lane says. Various experiments have been made, both in America and Kenya, by which anopheles were captured, sprayed with dye, and released at a distance from the site of capture, but these have not been carried out on a sufficiently large scale to be conclusive; the results indicate, at any rate, a tropism towards food. Nor is a stay-at-hospice habit invariable among anopheles; some species appear to leave the house immediately after feeding, while others remain in a sluggish state for some hours after feeding, and J. A. Le Prince in America found that children could be readily trained to kill every anopheles in the room. The importance of the destruction of replete anopheles as an antimalarial measure was demonstrated in the early days of the construction of the Panama Canal. The female anopheles is impelled to leave the house after feeding by the necessity for oviposition; during hibernation the insect does not feed and there is no oviposition, so that there is no danger of transmission of malaria. N. H. Swellengrebel has shown, however, that for *A. maculipennis* in Holland there is an intermediate condition, which he calls gonotropic dissociation, in which oviposition is in abeyance but feeding continues. When in this condition mosquitoes remain in the house where they have fed, and are capable of becoming malarious and transmitting the disease. Moreover, there is some evidence that anopheles sick of malaria become too sluggish and ill to leave the house for long at a time, and S. P. James describes them as finding a sheltered hole a few feet from the bed, from which they make a nightly sally to feed. The view put forward by E. Roubaud in 1919 that human beings are protected from malaria by the presence of animals in sheds or stables near the house has been considerably modified since then. He later declared that to be effective the animals must be housed in low, dark quarters free from draughts. Under conditions in which the human habitations share these same disabilities, however, Colonel Clayton Lane finds no satisfactory grounds for thinking that malaria-carrying anopheles prefer the blood of the animals to that of the men; he suggests by inference that to house man well is likely to prove a better antimalarial measure than to house animals badly. The value of screening of houses was established as long ago as 1900 when Sir Patrick Manson carried out his experiment in the Roman Campagna. The only protection employed by the experimenters was the adequate screening of their quarters, and not one of them acquired malaria, although they went about the country freely during the day.

---

[1] Housing and Malaria. A Critical Summary of the Literature dealing with this subject. By Lieut.-Colonel *Clayton* Lane, M.D., I.M.S., retd. League of Nations publications, 1931, iii., 6. Obtainable in Great Britain from George Allen and Unwin, 38, Great Ormond-street, London, W.C. Pp. 43. 1s. 6*d*.

Colonel Clayton Lane's summary serves to collate the evidence that malarial infection is acquired essentially in the house. In his opinion the chief protective measures lie in suitable disposition of buildings relative to anopheline breeding places, in their proper construction, and where necessary in the use of screening.

SOME RECENT POLICIES REGARDING PARTICULAR DISEASES.

UNDER this title Sir George Buchanan delivered before the Section of Public Health of the British Medical Association a presidential address which deserved the marked attention of the audience, and which, we hope, will be available shortly, in the full text, through the columns of the *British Medical Journal*. The general message of the address was that in dealing with public health policies in regard to particular diseases we should rely for our procedure to an increasing extent upon local experiment, the panacea in preventive disease being found wanting in proportion as knowledge and experience grow. Few, indeed, are the diseases which the epidemiologist can hope to curtail in spread, or to bar from a given locality, by one general set of methods. Psittacosis forms a solitary example of a particular infection, where complete exclusion from our own country, even in modern circumstances of inter-travel, was attended with success; and psittacosis may be a comparatively trivial disease, but Sir George reminded us that it was none the less responsible for over 100 cases within a few months recently, with 25 deaths.

The occurrence of communicable diseases, and the complexity of their manifestation, leaves psittacosis in a class by itself; indeed, it is rare that even the main lines of policy, directed against a particular disease, can be so generally applicable as to result in homogeneous international action. Referring to the methods now being tried in many countries to combat malaria, Sir George reminded his hearers that public health authorities in various parts of the world at one time offered, as their single policy against the spread of malaria, activities based on the intensive local attack of the breeding-places of anophelines. We know how successful this policy has been in certain mosquito-ridden areas, but in others the circumstances of the area have produced different procedures of prevention as practical knowledge of malaria increased. The limitations of quinine, for example, which had been suspected by many, especially those whose war service brought them into malarial districts, are now recognised, and drugs have been utilised which meet some of these limitations; and, again, the work which has centred round the Horton Laboratory, where all phases of malaria are studied in association with the manifestations of general paralysis, has introduced a new phase of study. In further development of arguments against a general trust in any therapeutic or preventive procedure, because it has proved, and is proving, beneficial at certain times or in certain places, the lecturer commented on the variations of public health policy now adopted in dealing with yellow fever and leprosy, but he chose as his principal example of a definite change in scientific thought the views held now upon isolation, immunisation, and the influence of carriers, when considered in connexion with scarlet fever and diphtheria. The hospital isolation of scarlet fever he described as representing a social convenience—"any local area which has once possessed it would not willingly dispense with it"—but he found no evidence withstanding examination that the spread of scarlet fever has been checked by isolation, or that either the severity or mortality has been diminished. Practical experience may thus be confirming the conceptions of scarlet fever entertained by the immunologists. Both in scarlet fever and in diphtheria we have, the lecturer considered, justification of the isolation hospital as a place of treatment and of observation—"the accent is shifted from *isolation* to *hospital*." This view of isolation hospitals has led to study within their walls of a variety of different diseases, and the close association of these institutions with bacteriological and clinical research is full of promise, and is displaying performance. While the routine in connexion with the detection of carriers has been much dispensed with, bacteriological study has been largely directed towards the production of artificial immunity. For diphtheria, systematic immunisation is now an accepted policy among the staffs of hospitals for infectious diseases and in certain schools and institutions, and much work has been done in the same direction for scarlet fever, though an immunising agent requires here to do more than prevent uncomplicated manifestations of the disease, a difficulty which has also occurred with small-pox where vaccination is a standard form of successful immunisation.

Small-pox constitutes a good example of possible value coming out of intensive local investigations, because of the remarkable variations in severity which attend different local outbreaks. Sir George Buchanan pleads for the establishment of local centres of research, not only here, but in connexion with the prevention generally of the greater scourges. He suggests that in this manner some of the problems of acute rheumatism in children and of the increasing cancer death-rate might be helped towards elucidation. He advocated the setting on foot of local effort inspired by local enthusiasm, and closed his address with these words: "It seems, indeed, even from the random examples I have given, that in dealing with public health policies in regard to particular diseases we can hardly have enough local experiment." The sentence is significant, coming from one of the chief officers of our national health department—a department too often accused of aiming at bureaucratic centralisation.

THE DIFFERENTIAL DIAGNOSIS OF ANGINA PECTORIS.

IT is not so long since the clinical picture of coronary artery disease, with its many variations, has been rescued from the profusion of symptoms labelled indigestion and made into a clinical entity. To those who have worked hard to differentiate the syndrome, it is depressing to observe signs that in diagnosis its cardinal features remain unrecognised in many quarters. In an article entitled Referred Pain of Gastro-intestinal Origin Simulating Angina Pectoris,[1] Dr. Robert Palmer does not convince us that confusion in diagnosis need still occur, certainly not that the reaction of such patients to "continued gastric régime" must be studied before a diagnosis can be arrived at. It is certainly true that reflex gastric symptoms are common in cardiac pain, but the features of the pain are usually clear cut. Dr. Palmer does not take into account the possible occurrence of intermittent claudication of the mesenteric vessels, when the mesenteric arteries are affected by arterios-clerosis; this possibility, with its resulting digestive symptoms, should be borne in mind with all patients showing marked atheroma of other vessels. The cases supplied to illustrate difficulty of diagnosis are few and incomplete. We are not told the blood pressure in any one case; this is an important omission, since patients suffering from high blood pressure may complain of cardiac pain for some years. No mention is made of the Wassermann reaction in any case. It is acknowledged that it is possible to mistake pain of gastro-intestinal origin for angina pectoris, but the mistake should be rare, in the light of recent knowledge, among those familiar with the manifestations of coronary artery disease.

CEREBRO-SPINAL FEVER.

SOME of the problems which arise in the prevention and treatment of cerebro-spinal fever were considered in our issue of Feb. 21st. Readers who require further light on these difficulties will find it in a report[2] just published by the Ministry of Health, which deals with the transmission of the disease by carriers, the value of serum, the use of vaccines, and the measures to be taken with contacts. The treatment recommended, apart from good nursing, includes early and repeated lumbar puncture, to relieve pressure and to promote drainage of the cerebro-spinal system; in addition the use of antimeningococcal serum is advocated, to be administered, if possible, with the first lumbar puncture. The administration should be repeated at 24-hourly intervals until recovery appears to be well established and the cerebro-spinal fluid has become clear. It should not be discontinued if the first examination of the C.S.F. yields no meningococci; nor should lumbar puncture be delayed if serum is not immediately available. The amount of C.S.F. escaping after lumbar puncture in adults is commonly in the region of 50 to 70 c.cm., and the amount of serum injected should on no account exceed the amount of fluid withdrawn; 30 c.cm. of serum is given as the usual intrathecal dose for an adult, and it is best injected with the patient anæsthetised, since the pain may be considerable. With infants, who do not tolerate the injection of serum well, the use of an anæsthetic is considered inadvisable. Satisfactory results appear to have been obtained in Rumania by giving a daily intrathecal dose of polyvalent antimeningococcal serum combined with an intramuscular dose of about 60 c.cm. of the same serum for at least three or four days. In spite of the promising results of serum therapy in the early stages, it has undoubtedly proved useless in many cases, partly because of the difficulty of assessing the probable therapeutic efficiency of antimeningococcal serums by laboratory methods, and partly because of the multiplicity of strains of meningococci responsible for sporadic cases, and apart from the local strains recognisable during an epidemic. At the present time it is thought that reliance must be placed on polyvalent serums. Vaccines, it is stated, may be useful during slow convalescence, and should consist, if possible, of killed cultures of the patient's own meningococcus, given subcutaneously in fairly large doses, beginning with 250 millions. No satisfactory data exist as regards the use of vaccines in prophylaxis. The swabbing of contacts is advocated with a view to the detection of carriers. To be effective, swabs should be taken from the upper end of the posterior pharyngeal wall, and contamination with saliva should be avoided. Fresh air and exercise, without other treatment, have been found to be the best means of freeing a carrier of the meningococcus; the use of a fine vapour spray of zinc sulphate, 1½ to 2 per cent., directed through the nostrils and mouth to the nasopharynx, appears to have been beneficial in some cases.

AN ADVISORY COMMITTEE TO THE BOARD OF CONTROL.

THE Board of Control, with the approval of the Minister of Health, have appointed a committee to advise them on questions arising in connexion with scientific and ancillary mental health services. The members are: Mr. L. G. Brock, chairman of the Board of Control (chairman); Sir Hubert Bond, F.R.C.P.; Mr. Robert Bruford, J.P.; Mr. W. E. Lovsey, J.P.; Dr. T. S. Good; Dr. Adeline Roberts, J.P.; Mr. J. C. Grime, J.P.; and Prof. J. Shaw Bolton, F.R.C.P., with Mr. P. Barter as secretary. The Mental Treatment Act, which came into operation on Jan. 1st, confers upon local authorities powers to provide for out-patient treatment and for the after-care of mental patients, and, subject to the approval of the Board of Control, to undertake or to contribute to research in regard to mental illness. The Board have appointed the advisory committee to assist them in the consideration of schemes of research submitted for their approval, and in regard to such questions as the organisation of social services in connexion with out-patient treatment and after-care, on which local authorities may seek the Board's guidance. On technical questions relating to research the advisory committee will have the expert advice of members of the Medical Research Council's committee on mental disorders.

LONDON HOSPITAL SATURDAY FUND.—At a meeting of the council last week it was reported that the fund during the past year had decreased by £5000. The fall was explained to be due to competition from similar organisations and to the general financial stringency.

EXTENSION OF WORKSOP VICTORIA HOSPITAL.—A new wing of this institution was recently opened by Viscount Galway, to whose grandmother, Henrietta, Lady Galway, it owed its inception in 1867, and dedicated by the Bishop of Southwell.

SPECIAL ARTICLES

THE CEREBRAL CORTEX IN MAN.

PROF. FOERSTER'S LECTURES.

UNDER the auspices of the University of London an important series of lectures on the cerebral cortex was delivered recently by Prof. Otfrid Foerster of Breslau. Prof. Foerster is one of the foremost neurologists of the day and his work has always been distinguished by the contributions that he has been able to make from his study of patients to the anatomy and physiology of the nervous system. Although trained as a neurologist he has for many years done his own surgery, and during operations on the brain he has systematically developed the work of electrical stimulation of the human cortex begun by Horsley, Fedor Krause, Cushing, and others. It is safe to say that he is now without equal in his knowledge of this subject.

Prof. Foerster began by referring to the work of Oscar and Cécile Vogt. The Vogts have shown that differing motor effects obtained by stimulation of various parts of the cerebral cortex of animals correspond to differences in the arrangement, number, and morphological characters of the nerve-cells and medullated nerve-fibres in the various parts of the cortex. They have thus been able to divide the cortex into a number of sharply defined areas each giving a specific motor effect on stimulation and possessing its own specific architectonic structure. Prof. Foerster's results in man agree closely with those obtained by the Vogts and he employs the system of terminology that they introduced (see Figure).

The lecturer then proceeded to discuss various areas of the cortex in man. For each area he described the architectonic structure, the effects of electrical stimulation, the effects of irritation by pathological lesions, and the effects of partial or complete destructive lesions. In the surgical treatment of epilepsy he has frequently had occasion to stimulate and excise portions of the cortex. He has also observed with minute care the effects produced by tumours and other lesions of the cortex and in the course of these lectures he cited over 100 cases.

Precentral Gyrus.

Area 4.—The precentral gyrus in man is composed of two distinct areas: the area 4, which lies in and immediately in front of the Rolandic fissure, and a more anteriorly placed area called by the Vogts 6 a_α (see Figure). The area 4 gives origin to the fibres of the pyramidal tract. Stimulation of a point in this area by threshold galvanic stimuli, with the patient under local anæsthesia, or by faradic stimuli with the patient under general anæsthesia, produces an isolated movement of a single segment of the extremities or a single part of the trunk or head. In most instances the effect is on the opposite side, but stimulation of the parts supplying the upper part of the face, the pharynx, vocal cords, and the muscles for closing the jaw gives bilateral reactions. Occasionally stimulation of the areas for the trunk and thigh also produces bilateral movement. Stimulation of the area supplying the neck gives a response chiefly of the sternomastoid of the same side, the head thus being turned to the opposite side, and the external pterygoid muscle also has ipsilateral representation. The arrangement of the parts of the area 4 corresponding to the various movements is well known. In man there exist separate foci for each of the fingers and these occupy a relatively large part of the area. The focus of the fifth finger is the most superior, that of the thumb the most inferior. To obtain circumscribed effects by electrical stimulation in man it is necessary to use threshold stimuli and the surface of the convolution must be dry. Under such circumstances the effect of galvanic stimulation may be limited to a single muscle or even to part of a single muscle. It is thus clear that the precentral gyrus contains separate innervation not only for single muscle groups but also for single muscles. The threshold of these foci varies from one individual to another, the average being 1–2 ma. (milliampères).

Area 6 a_α.—In monkeys the entire surface of the precentral convolution is occupied by the area 4 and the area 6 a_α lies in the frontal convolutions. In man the area 4 lies chiefly in the Rolandic fissure and the area 6 a_α occupies the greater part of the summit of the precentral convolution. In man stimulation of points of the area 6 a_α produces the same isolated motor effects that are obtained by stimulation of the area 4, and there is the same detailed subdivision into foci for single segments of the limbs, but the threshold is much higher. These isolated effects from stimulation of the area 6 a_α are due to transmission of the stimulus to the area 4, for they are abolished by an incision into the cortex between the two areas, or by abrasion of the superficial layers of the cortex in the area 6 a_α. Under these circumstances, or if the pyramidal tract has been previously destroyed by disease, strong faradic stimulation of the area 6 a_α produces rotation of the head, eyes, and trunk to the opposite side (adversive movements), and the contralateral limbs carry out complex synergic movements of a flexor or extensor character. These movements are brought about by direct (extrapyramidal) innervation from the area 6 a_α to the subcortical and other lower centres.

Cases of Jacksonian epilepsy and of epilepsy produced by lesions in the precentral gyrus when the pyramidal tract had previously been destroyed were cited to confirm the results of stimulation. The lecturer then described a remarkable series of cases of destructive lesions of the precentral gyrus to show the essentially focal nature of the resulting paralysis when a limited part of the precentral gyrus was destroyed. Thus, from a gunshot wound affecting the medial part of each "motor" area in the paracentral lobules, a patient had bilateral spastic paralysis of both feet. The movements of the legs and thighs were not affected. This patient also had retention of urine. Prof. Foerster believes that the foci of the bladder and rectum lie in the paracentral lobule. Another case, of syphilis affecting one precentral gyrus, had spastic paralysis limited to one foot which superficially resembled a case of peroneal palsy. A case of meningioma of the falx cerebri observed through a number of years showed spastic paralysis of both legs and retention of urine. Gradually the paralysis extended to involve the muscles on the right side of the abdominal wall and diaphragm, the right shoulder and arm, and finally the forearm. The hand and fingers were never impaired. This patient never had headache or papillœdema. The case demonstrates clearly by the succession in which the different parts became paralysed the somatotopic focal subdivision of the precentral convolution. Another case of cortical lesion showed paralysis limited to supination of the forearm and extension of the wrist and fingers of one side. Cases in which the thumb or one or two fingers alone were paralysed were not rare, and isolated cortical paralysis of the interossei of one hand had also been observed. Excision of limited parts of the precentral convolution was followed by similar circumscribed focal palsies, but these were often more or less transient, especially in children. Recovery in such cases must be attributed to the more or less diffuse arrangement in the cortex of the motor foci of single muscle groups.

Frontal Convolutions.

Area 6 a β.—The area 6 a β (the frontal adversive field) occupies the posterior part of the superior frontal convolution. In man it does not react to galvanic stimulation even under local anæsthesia. Faradic stimuli of high intensity must be used. The effect produced is similar to that obtained by stimulation of the area 6 a α when the pyramidal tract has been destroyed—rotation of the head, eyes, and trunk to the opposite side and complex synergic movements of flexion or extension of the contralateral arm and leg. This response is still obtained after the areas 4 and 6 a α have been destroyed. Thus the area 6 a β has its own motor pathway to the subcortical centres. The movements obtained by faradic stimulation of the area are easily converted into an epileptic attack, and attacks of exactly the same type are produced by many different pathological processes involving the area 6 a β. Most of the cases cited had been completely relieved of their fits by excision of the area and this procedure was not followed by any recognisable defect of motility.

Area 8 αβδ.—This area (the frontal eye field) occupies the posterior part of the second frontal convolution. In many cases it reacts to galvanic stimulation (threshold, 4·0 to 8·0 ma.), but in other cases faradic current is necessary to obtain an effect. The response is an isolated movement of the eyes to the opposite side, and occasionally also in an upward direction. Strong faradic stimulation produces a convulsion, which may be limited to the eye muscles, but in most cases other movements occur, indicating a spread of the stimulus to the area 6 a β or to the areas 6 a α and 4. These attacks may be confused with attacks originating from the area 6 a β unless it is recognised that the fits begin with clonic movements of the eyes to the opposite side and only later involve the muscles of the head, trunk, and limbs. Pathological lesions of this area produce fits similar to those observed experimentally. Excision of the area is in some cases followed by more or less complete paralysis of lateral movement of the eyes to the opposite side, but this is temporary.

Area 6 β.—This small area occupies the most inferior part of the precentral convolution. Electrical stimulation of it produces rhythmic coördinated movements of the lips, tongue, mandible, pharynx, and larynx. The area appears to be unique, inasmuch as stimulation of it by a continuous galvanic current produces rhythmic movements, and the effect outlasts the stimulus. No other area of the cortex behaves in this way. Epileptic convulsions originating from the area 6 β begin with the same type of movements—chewing, licking, swallowing, and grunting movements—but in most cases the attack spreads to the adjacent areas 4, 6 a α and to the postcentral convolution.

The Postcentral Convolution.

Area 3, 1, 2.—The area 3, 1, 2 occupies the postcentral convolution and extends to the median surface of the brain, where it occupies the posterior part of the paracentral lobule. Faradic stimulation of the area is followed by paræsthesias, seldom by pain, in different parts of the body. The area shows a detailed somatotopic subdivision into a large number of sensory foci, each of which represents a special segment of the limbs or a special part of the body. The arrangement is in the same order as in the precentral convolution. Motor effects also follow stimulation of the postcentral convolution. They are obtained best by galvanic stimulation and are of the same isolated character as the effects obtained by stimulation of the precentral convolution, but the threshold is 2–4 ma. higher. They depend on the integrity of the area 4 and of the pyramidal tract. If either of these is destroyed no isolated motor effect can be obtained from the area 3, 1, 2, but strong faradic stimulation may still produce complex movements identical with those obtained by stimulation of the area 6 a β. Fits produced by lesions in the postcentral convolution begin with focal paræsthesias which spread. Motor discharges may then occur, usually at a distinct interval after the wave of paræsthesia.

A number of cases illustrating sensory disturbances by lesions of the postcentral gyrus were cited to show that focal lesions affect the sensibility of limited areas of the limbs and trunk. Thus, in one case of traumatic injury showing sensory Jacksonian attacks beginning with paræsthesias in the ring and little fingers, the disturbance of sensibility was limited to these two fingers. In many such cases of circumscribed lesions the anæsthesia of the extremities is limited by a circular line, but in others the areas of anæsthesia occur in the form of bands and strips along the extremities (anæsthesia of the axial type). It is possible that each sensory focus in the postcentral convolution is subdivided into anterior and posterior parts, the former corresponding to the lateral, the latter to the medial half of the segments of the extremities.

Loss of sensibility following destructive lesions of the postcentral convolution is recovered from to a considerable degree, and this is partly due to the fact that some afferent pathways do not cross, but end in the cerebral hemisphere of the same side. The intact hemisphere may substitute for the impaired hemisphere to a certain extent. But even in bilateral postcentral lesions a certain degree of recovery may be observed. This is explained by the fact that sensory areas in the cortex are not limited to the postcentral convolution. The superior parietal lobe is certainly part of the sensory cortex in man. The work of Dusser de Barenne in monkeys suggests that the sensory cortex has a wider distribution than hitherto supposed, but so far Prof. Foerster has no evidence that areas other than those described above contribute to the sensory cortex in man.

Destruction of the postcentral convolution is followed by disturbance of mobility as well as by defects of sensibility because coördination of movements depends on the integrity of the afferent pathways. Various types of ataxia occur.

Parietal Lobe.

Area 5 a.—This relatively small area lies in the upper part of the superior parietal lobe, immediately behind the postcentral convolution, and extends to the median surface of the hemisphere. In man it reacts in most cases only to faradic current, but in a few cases galvanic stimuli of high intensity (6-10 ma.) are also effective. Motor and sensory effects are observed. The motor response consists of complex movements of the opposite arm and leg similar to those obtained from the area 6 a β; but in addition the arm and rarely the leg of the same side also take part in the movements. Furthermore, if stimulation is limited to the area 5 a and does not radiate to the area 5 b the head and eyes are not turned to the opposite side. The sensory effect consists of widespread paræsthesias and sometimes pain appearing simultaneously in the trunk and limbs of the opposite side, and sometimes also in the bladder and *rectum*. Epileptic attacks originating from lesions of this area are often preceded by a sensory aura which differs from that occurring in lesions of the postcentral gyrus, in that it involves the various parts of the opposite half of the body simultaneously rather than successively. The motor manifestations of these fits are similar to those obtained by stimulation of the area. Excision of the area 5 a is followed by defects of sensibility.

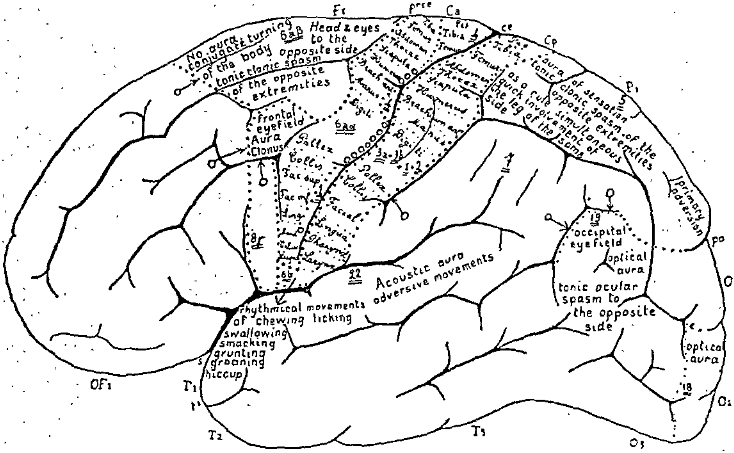

Diagram modified from an illustration in a paper by C. and O. Vogt in "Die Naturwissenschaften" (1926, xiv., 1101, published by Julius Springer, Berlin). A similar diagram was used by Prof. Foerster in his lectures.

Area 5 b.—This is a large area in man, and occupies the greater part of the superior parietal lobule and precuneus. It reacts to strong faradic currents only. The primary motor effect is deviation of the head and eyes to the opposite side but if the anterior part of the area is stimulated movements of the contralateral limbs occur, due to spread of the stimulus to the area 5 a. Sometimes sensory effects are also produced, and they resemble those obtained by stimulation of the area 5 a. In one case removal of a cyst from this area produced in the patient a feeling that she was turning to the opposite side and falling from the operating table. In another patient attacks of the 5 b–5 a type were preceded by vertigo and faradic stimulation of the interparietal fissure at operation produced a similar feeling. From these and other cases Prof. Foerster thinks that the interparietal area may be the cortical area in which the vestibular pathways end.

Areas 7 b and 7 a.—These areas comprise the inferior parietal lobe. Prof. Foerster has never observed any sensory effect from stimulating these areas, not even with the strongest faradic current. No disturbance of sensibility has been observed after excision of these areas. With very strong faradic currents rotation of the head and eyes to the opposite side was observed, in a few cases only, when the posterior parts of the area 7 b were stimulated.

Temporal Lobe.

Area 22.—The area 22 occupies the posterior part of the superior temporal convolution and its borders have not yet been fully defined. Stimulation produces adversive movements similar to those obtained from the area 6 a β. Sensory effects may also be obtained in the form of noises and sometimes voices of obscure character. Epileptic fits originating from the area 22 may show an acoustic aura, and in a few cases the fit was produced by a sudden sharp noise. Thus in one boy suffering from the effects of an old birth injury of the area 22 an attack could be provoked with experimental promptness by letting an object fall on the floor, or by the noise of a passing tramcar.

Specific Functions of the Motor Area.

Summarising the effects obtained from the different motor areas it is seen that they may be divided into pyramidal and extrapyramidal areas. Isolated effects can be obtained from stimulation of the areas 6 a α, 4, and 3, 1, 2; they depend on the integrity of the area 4 and its motor pathway the pyramidal tract. Thus the area 4, the area pyramidalis, is the specific area for isolated innervations. All the other areas, 6 a β, 5 a, 5 b, 22, and, when the area 4 or the pyramidal tract is destroyed, the areas 6 a α and 3, 1, 2, react with complex movements of rotation of the eyes, head, and trunk to the opposite side, and of flexion or extension of the contralateral limbs. These are the extrapyramidal areas. Both groups coöperate when voluntary movements are performed. If the area 4 or the pyramidal tract is destroyed isolated movements can no longer be performed but voluntary movement is by no means completely abolished. Complex flexor or extensor movements of the affected limbs can still be performed, but the movements are combined; this is even more evident when both pyramidal tracts are destroyed. Thus, in spastic tetraplegia all four extremities move together, whichever one of them is moved voluntarily. This reveals the specific function of the extrapyramidal areas. The pyramidal tract takes an uninterrupted course from the cortex to the anterior horn cells of the spinal cord. It is a fast-train connexion between the cortex and the cord. All the other motor pathways, originating in the extrapyramidal cortical areas are interrupted by relay stations in a number of subcortical centres before they reach the anterior horn cells. They are slow-train connexions between the cortex and the cord.

Occipital Lobe.

Area 17.—This is the area striata. In monkeys Sherrington obtained movement of the eyes to the opposite side, but in man stimulation produces no motor effects. The area reacts with optic sensations. When the occipital pole or the posterior part of the area striata on the medial surface is stimulated, the patient sees a stationary light or stars immediately in front of him. When the anterior part of the area is stimulated the light is seen in the peripheral parts of the visual field and is moving towards the centre of the field. If the superior lip of the calcarine fissure is stimulated the light comes from below; when the inferior lip is stimulated it comes from above.

Area 18.—This, the area occipitalis, lies on the lateral surface of the occipital lobe immediately in front of the area 17 and it extends to the medial surface of the hemisphere where it lies both above and below the area 17. Faradic stimulation of this area also produces optic sensations.

Area 19.—The preoccipital area occupies the rest of the occipital cortex and it lies chiefly on the convex surface of the hemisphere. Faradic stimulation produces sensory and motor effects. The sensory effects are optic phenomena of a rather complex character: the patient not only sees a light, stars, or colours, but also figures, people, animals, and so forth. The motor effect consists of movements of the eyes to the opposite side. These results conform with clinical and operative observations of patients suffering from lesions of this area. A number of interesting observations were described, and Prof. Foerster concluded by citing evidence in favour of bilateral representation of the macula.

HARROW MOTHERS' HOSTEL.—In the year 1930–31 there were 122 admissions and as many deliveries. The total weekly cost per patient was £5 14*s.*, and the average weekly payment by patients was £2 19*s.*

SUSSEX PROVIDENT SCHEME.—This organisation for hospital and specialised medical services continues to increase its scope. During the first six months of the current year £8468 was paid to the coöperating institutions, of which the Royal Sussex County Hospital received £3200, and the Royal Alexandra Hospital for Sick Children £1057. The sum of £323 was paid to the Brighton Corporation; and £325 was refunded to subscribers for treatment at non-coöperating hospitals, &c. In the ten years the scheme has been in operation no less than £81,493 has been distributed to hospitals and kindred institutions.

CASUALTIES AND STATISTICS OF THE WAR.

THE OFFICIAL HISTORY.

THE last volume of the "Official History of the War"[1] is unique in that Great Britain is the only country that has published statistics dealing with total casualties from front lines to base. The volume records over 11,000,000 casualties sustained by the British forces at home and overseas. Despite the unavoidable omissions, the wastage which it represents proclaims the cost of modern warfare. The hardship and sacrifice behind the figures can find no place in the analysis, but have nevertheless inspired it in the hope of furthering research to alleviate suffering and prevent disease. The work is largely due to the determination of the late Sir William Leishman that the lessons to be learned from this wealth of material should be made available for all time.

The first chapter relates the vicissitudes through which the book passed in preparation, and the difficulties of striking a balance between theoretical perfection and economy. By focusing attention on the difficulties of building up an organisation to compile statistics, it may help in the evolution of a simpler method for the future. The peace-time system soon proved quite inadequate as the forces increased and patients were rapidly transferred. In 1917 the War Office took over the cost of routine statistical work and instituted the official medical history cards, which were collected by the Medical Research Council to be used later as data for statistics. Unfortunately, even this scheme miscarried, and mistakes were made on all sides, so that in the end the only cards which were of any value were those from the British Expeditionary Force in France. By May, 1919, little progress had been made in obtaining statistics that would be helpful for general and Army medical purposes, although a great deal had been done in compiling and filing twenty odd million individual records. An additional staff was therefore appointed, and when the register of index cards was complete—in 1921—it was decided to examine two sample sets, each of about 500,000 cards, to form the basis of a statistical volume. Finally, it was decided that the book must be limited to the outstanding problems of casualties, man-power and wastage, and to tabulating and publishing the type of information which was regularly called for or constantly used during the war by staff, administrative, and medical officers.

The Magnitude of the Casualty Problem.

Casualties are classified and analysed according to their area, and non-battle casualties and the chief causes of inefficiency among the troops are discussed, while the concluding chapter records the work of the Ministry of Pensions since its inception. The after-effects of the war are strikingly illustrated by the fact that—exclusive of Dominion and other overseas forces—2,414,000 individuals, or 40 per cent. of those who served, were affected by war service in the sense of death or some disablement for which compensation was given.

"If," the authors conclude, "these figures are remembered when preparations are being made, then questions relating to the supply of additional personnel, equipment and transport for the medical services will have a greater interest for all branches of the Army, and they will be considered not only as a means of succouring sick and wounded, but as important factors in preventing wastage, conserving the man-power of the nation during hostilities, and reducing expenditure after the war."

---

[1] Casualties and Medical Statistics of the Great War. By Major T. J. Mitchell and Miss G. M. Smith. H.M. Stationery Office. 1931. Pp. 382. £1 1*s.*

The authors feel that the magnitude of the problem is scarcely realised, rarely studied, and seldom fully appreciated. As Sir William Robertson remarked, "The longer peace continues, the more difficult it is to prepare for war," and the medical services, like other services, lack the experience in handling and providing for large masses of men. The expansion of the forces in the war was without parallel, and the organisation had to be very different from that of peace. In August, 1914, the Royal Army Medical Corps numbered 1279 officers and 3811 other ranks, while in August, 1918, it numbered 10,178 officers and 100,176 other ranks, exclusive of Territorial forces. Moreover, 637,746 hospital beds were equipped and maintained. Another essential basis of calculation is the probable number of sick, dead, invalids, evacuations, and men returned to duty. Knowledge of local conditions in foreign countries will prevent "misfits" in sending unsuitable troops or equipment to foreign areas. Moreover, Eastern races may be added to the Army as troops for multifarious auxiliary duties, and failure to study their races, customs, and diets may involve serious casualties. Our labour battalions in France in 1917 and 1918 were composed of 117,848 Indians, Egyptians, South Africans, Fijians, and Chinese, for whom special hospitals, special diet, and special treatment had to be arranged. The native followers of the East African Expeditionary Force numbered nearly three times as many as the troops, and it was found that much disease might have been avoided if men from low-lying districts had been sent to low-lying country, and those from the highlands to hilly areas.

BATTLE CASUALTIES.

Where the figures are complete, they show that, of the sick and wounded admitted to medical units, 3·04 per cent. died, 58·10 per cent. were returned to duty, and 37·41 per cent. were evacuated overseas. In all theatres the percentage of deaths from disease or injury was lower than in the South African War, despite the much greater destructiveness of modern armaments; 55 per cent. of the deaths from wounds and 32 per cent. of those from disease or injury occurred in casualty clearing-stations and other front-line medical units. About 82 per cent. of wounded and 93 per cent. of sick or injured were returned to some form of duty.

The authors stress the futility of supplying the Army with the finest doctors, nurses, and material available unless casualties can be systematically collected, rapidly evacuated, and suitably accommodated, and urge the vital importance of coöperation between the medical services, the army commander, and the forces in the field. Our armies were insufficiently supplied with stretcher-bearers at the beginning, but gradually learned that it was worth while to supply enough men, and fit men, for this work, and to arrange very carefully the programmes, allotments, and time-tables for transport.

The fact that 1,140,398 wounded were admitted to casualty clearing-stations in France during 1917 and 1918 gives some idea of the work done by these units. Of the total number, 30 per cent. required and received immediate operation. Since 55 per cent. of the total deaths from wounds occurred in casualty clearing-stations, it is obvious that high medical and surgical skill should be available in them.

The authors discuss transport, mentioning the useful ambulance transport steamer or barge for river work; during the war 3,443,507 sick and wounded were evacuated from the front to the base in France by ambulance train or improvised ambulance train. Of the total sick and wounded admitted to casualty clearing-stations, 75 per cent. of the sick, 90 per cent. of the wounded, and 81 per cent. of the total sick and wounded required evacuation to the base, and transport accommodation had to be provided for 58 per cent. sitting cases and 42 per cent. lying-down cases. The authors think that the provision of vacant beds in base hospitals should be not less than 33 per cent. of the equipped beds; during the war the percentage was generally below this figure. Obviously such a task must involve forethought, organisation, and—above all—liaison between staff and medical officer. At the beginning of the war the text-book methods of evacuation broke down, but fortunately in France the service was soon restored. The early and systematic collection and evacuation of all casualties is a primary principle of the conservation of man-power.

Useful and interesting tables in this chapter show the percentages of wounds caused by different weapons, the regional incidence of wounds, and the percentage of casualties suffered by the various arms of the service.

In 1917, 30 per cent. of the sick and 20 per cent. of the wounded were admitted to convalescent depôts at the base; these units are invaluable during epidemics, for slight casualties, and to give exhausted men a period of recreation and hardening.

"The outstanding lesson of the war in this respect," the chapter concludes, "centres round the advisability of sending 1 or 2 per cent. of the hospital accommodation and 0·5 per cent. of the convalescent depôt accommodation with the advance troops."

NON-BATTLE CASUALTIES.

It is a platitude to medical men that the losses occasioned by the enemy are equalled and often surpassed by the silent intangible enemy of disease. In the war of 1914-1918, the invisible enemy claimed two casualties for every one inflicted by weapons of war. Of the non-battle casualties, excluding those of East Africa during 1914 and 1915, 1·83 per cent. died, and the daily percentage of strength reporting sick varied between 0·05 in the United Kingdom and 0·72 in East Africa. An interesting table shows the principal causes of admission to hospital, with the ratio per 1000 of ration strength, compared with figures from the South African War. As the chapter points out, the best method of enlisting the interest and coöperation of all ranks towards further progress in eliminating disease is to show plainly the wastage that it causes. The tables in this chapter deal with ordinary infectious diseases, Eastern infections, tuberculosis, pneumonia, venereal diseases, malaria, dysentery, influenza, frost-bite, trench-foot, war nephritis, and jaundice.

The succeeding chapters discuss the casualties according to their area: the United Kingdom, France and Flanders, Italy, Macedonia, the Dardanelles, Egypt and Palestine, North Russia, East Africa and South-West Africa, with a final chapter on the South African War for comparison, and another which analyses the million odd British casualties admitted to medical units between 1916 and 1920.

The Work of the Ministry of Pensions.

The last chapter aims to give a broad presentation of the Ministry's medical tasks and accomplishments, with a general analysis of the outstanding medical characteristics of post-war disablement. The Ministry was faced with the task of providing treatment as well as boards; artificial limbs, plastic surgery, mental and psychological treatment, sanatoriums, training for the blind, homes for the paralysed, and vocational training for the disabled were all demanded. The total British officers, nursing sisters, and other ranks, excluding Dominions and other overseas troops, who served during the war was approximately 6,000,000; at the time of the Armistice some 12·5 per cent. of these were dead, and some 10 per cent. had been discharged as disabled. By March 31st, 1930, the disablement total had increased to 27·7 per cent., or a figure of 1,664,000. The chapter discusses the various disablements for which compensation has been paid, and their stablilisation. Diseases of the heart, lungs, and brain remain at the present day the most conspicuous items in the State's liability, while the wounds, despite their greater number, have mostly healed. In the first awards made in 1920–21, wounds, malaria, and functional diseases of the heart headed the list, while as time went on tuberculosis, respiratory diseases, organic diseases of the heart, and psychoses relatively increased. Ear diseases, rheumatism, and dysentery remained remarkably even in proportion. Stabilisation was possible at an early date for wounds, amputations, malaria, neurasthenia, and functional diseases of the heart. Assessments in the 70 to 100 per cent. group are principally made up of tuberculosis and psychosis, while the "30 per cent. and under" category is largely made up of malaria, neurasthenia, rheumatism, and functional diseases of the heart. There are still approximately 113,000 pensioners whose disability has such an uncertain prognosis that the compensation cannot be stabilised. "General surgical" disabilities tend to increase in proportion towards the end of the period under review, thus showing the importance of surgical conditions as a continuing cause of institutional care.

It is impossible to do more than indicate some of the outstanding points in this extraordinarily informing and important volume; it must be consulted by all those who have any concern with the welfare of armies, and will be of great interest to all medical men.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

ABORTION AND BIRTH-RATE.

THE number of abortions in Hungary have more than doubled in the last 20 years; at the same time the birth-rate has fallen from 40·5 to 24·7 per 1000. The number of abortions amount to between 110,000 and 120,000 every year, and of these 70 per cent. are criminal abortions. The cause of this state of affairs is attributed to the lax standards of doctors as to indications for induced abortion. According to Hungarian law, pregnancy may be interrupted only if the life of the mother is earnestly menaced by pregnancy as such. The actual text of the law does not recognise even this indication, although legal practice has countenanced it. According to prominent Hungarian gynæcologists, the law should be revised and re-worded. In a recent lecture, Dr. Fekete, lecturer to the University of Budapest, discussed in what way the induction of abortions by qualified doctors should be regulated so as to spare the doctor from having to make difficult decisions when approached by patients. It is generally held here that to allow artificial abortion without restriction would be equivalent to national suicide. In Soviet Russia artificial abortion was declared permissible in 1920, but only in institutions, and this has not proved an ideal method of dealing with the problem. The public is not wholly aware of the dangers of abortion; the mortality amounts to 1·2–3 per cent., and morbidity follows in 14 per cent. of the cases, even if the operation is performed in well-equipped, modern operating theatres. In Hungary more than 1200 women succumb to artificial abortion every year, and 6000 to 8000 women have ill-health following the operation. Dr. Fekete pleads that the loss of population due to abortion ought at least to be compensated for by the increased care and protection given to mothers and infants. In the country the proportion of maternity beds to births is 990 to 200,000. In some places the ambulance has to carry a woman in labour a distance of 35 to 70 miles. The Hungarian system of children and infant protection is a very fine one, but it ought to be extended not only to the indigent, but also to families with small incomes.

THE BUDAPEST BRAIN RESEARCH INSTITUTE.

The Budapest Brain Research Institute was founded 20 years ago by Prof. Schaffer, who still directs its activities. Two years ago he was awarded the Ramon y Cajal international prize, and now, on the twentieth anniversary of the foundation of his institute, he has collected the more recent research work emanating therefrom into a substantial volume, dedicated to Prof. Ramon y Cajal. During the past year workers at this institute have published 143 original papers, most of which have appeared also in the German "Hirnpathologische Beiträge." Considering the critical financial conditions now prevailing in Hungary, the maintenance of such an institute is a great sacrifice on the part of the State, but owing to the high reputation of the institute, the Government is ready to continue to support it.

THE PORGES-POLLATSCHEK TEST OF PREGNANCY.

At the recent meeting of the Royal Medical Society Dr. Göczy read a paper on his experience with this test on 50 pregnant and 50 non-pregnant women. The basis of the test is a skin reaction, the skin of pregnant women being said to be less sensitive to the injection of prolan than that of non-pregnant women. The injection of 0·2 c.cm. prolan intracutaneously in women causes a bright pink reaction 2 to 3 c.cm. in diameter; this conspicuous reaction is said to be entirely absent when the woman is pregnant. Göczy has experimented also with glanduantin and præhormon, both of which hormones correspond to the prolan of Zondek, with the difference that 1 c.cm. of prolan contains 100-rat units, while an equivalent amount of the other substances contains only 30 units. The test was a failure in 15 of the 50 pregnant women and in 22 of the control cases. Similar results were obtained by other Hungarian investigators, who have arrived at the conclusion that the test is valid neither for the confirmation or for the exclusion of pregnancy.

THE VISION OF MOTOR-CAR DRIVERS.

The Hungarian Government is elaborating new rules for road traffic with a view to decreasing the number of accidents, which have recently increased in number to an alarming extent. The general health examination of drivers will also be revised and new requirements will be set up. In this connexion

Prof. Grosz has observed that the standards of sight demanded vary in different countries. Some authorities hold the view that *non-professional* drivers need not be examined at all. According to Prof. Grosz, the accidents which can be brought into definite causal reaction with the bodily defects of drivers amount only to 1·5 per cent. of all accidents. The number of non-professional drivers in all countries is now very high; in France it is estimated at about 1,000,000, in Belgium as 140,000. The physical examination of such large numbers of people would give rise to great difficulties. Perhaps it is for this reason that the United States, Great Britain, and France do not conduct physical examination on all drivers. This attitude is strengthened by the experiences of the insurance companies, which indicate that accidents caused by the physical defects of drivers are very rare. Even in those countries where tests for physical fitness are held, such as Germany, Denmark, Italy, Norway, and Switzerland, persons with only one eye are allowed to drive cars. In Hungary, at the present time, a higher standard of vision is required from professional than from non-professional drivers.

PROF. ERWIN TÖRÖK.

On the invitation of the central committee of the Hungarian post-graduate medical courses, Prof. Erwin Török, who now teaches ophthalmology at the New York Policlinic Medical School and Hospital, delivered some lectures here in June. Prof. Török is a Hungarian by birth; from 1899 to 1906 he acted as assistant at the clinic of Prof. Emile Grosz, who presided on the occasion of his lecture on Syphilis and Trauma, and welcomed him to Budapest.

MEDICINE AND THE LAW.

Accommodation in Mental Hospitals.

RECENT proceedings in the Chancery Division may focus public attention on the difficulty of housing what used to be called "pauper lunatics," now more happily named by statute "rate-aided patients of unsound mind." According to the Board of Control's annual report for 1929, experience shows that when there is a shortage of accommodation the admissions fall; they rise immediately additional accommodation is provided. That report described the position as "very serious" except that visiting committees as a whole were found to be increasingly aware of the need for additional accommodation to meet immediate and future requirements. More recent information, contained in a Board of Control circular issued last May, was quoted in the recent Chancery proceedings. The overcrowding as at Jan. 1st last was stated to amount to 452 beds on the male side and 1635 beds on the female side; there were only 27 hospitals with 10 or more vacant beds on the male side and only 10 hospitals with similar vacancies on the female side. The circular warned local authorities that they could no longer hope to avoid overcrowding by resort to contract accommodation. Contract arrangements were useful as a temporary measure but should not be adopted if, as frequent complaints indicated, it involved sending patients so far from their homes as to make visiting prohibitively expensive.

The case in the Chancery Division concerned the patients from East Ham which, until its incorporation in 1913, was part of Essex for lunacy purposes and sent its patients to the county institutions. In July, 1929, East Ham made an agreement with the committee of visitors of the county of Essex and borough of Colchester mental hospitals for the reception of its patients. The agreement was to remain in force (unless earlier determined by the Minister of Health) until June 24th, 1930, as from which date the East Ham corporation undertook to remove all its patients to a hospital which it would itself provide. At one time, it appears, the patients concerned under the agreement numbered 200, but 108 had been moved in the past two years. Essex and Colchester complained that East Ham had failed to carry out its undertaking; they asked Mr. Justice Eve to order specific performance of the agreement to remove the patients. East Ham admitted that it had no defence. There was a scheme on foot, provisionally sanctioned by the Board of Control, for joining with Southend in the provision of an institution. The Board, it was said, had refused to allow East Ham to provide a separate institution of its own. East Ham submitted to an order of the Court admitting the duty to remove the patients and undertaking to press on the joint scheme with Southend (see p. 330), paying meanwhile contract rates previously in force. Essex and Colchester are to have liberty to apply for a mandatory injunction if, before Jan. 17th, 1932, East Ham has not removed 25 of its patients. The rate of removal is to be 25 patients every six months, so that there should be a complete clearance in three years—the period likely to be wanted for providing the proposed joint mental hospital for which special premises and an adequately trained staff will, of course, be required. The high proportion of female patients to male patients is an added difficulty; to meet this the order directs that each batch of 25 patients removed shall consist of 20 females and five males.

The Eyesight Standard for Motorists.

The Master of the Rolls has hinted that the Minister of Transport might revise the eyesight qualification for motorists. He was delivering judgment in the Court of Appeal in proceedings arising out of the refusal of the Cumberland county council to renew a motor-car driving licence in what was evidently rather a hard case. Every applicant for a licence has to make a declaration of physical fitness. The declaration involves, amongst other things, answering a question whether the applicant can read at 25 yards in good daylight (with glasses if worn) a motor-car number-plate containing six letters and figures. The applicant frankly admitted that the letters and figures seemed blurred to him, but he could claim that he had driven for eight years without an accident, and he gave a list of various long journeys which he had made by road. He could see persons or animals on the road two or three hundred yards off and cars at a much greater distance. His statement, said Lord Hanworth, showed that he was a capital driver and a driver of experience. "It is impossible to avoid regretting that the question in the form is put in the terms stated, because it would seem that a driver of skill and care is unable to answer in the affirmative a test made for the purpose of driving but which may be ill-suited for the purpose of securing capacity and fitness to drive."

The difficulty arises over Section 5 of the Road Traffic Act as elaborated by the Motor Vehicles (Driving Licences) Regulations made last November. The declaration of physical fitness (prescribed by the Regulations) contains questions as to epilepsy, sudden attacks of disabling giddiness or faintness, and the loss of either hand or foot, in addition to the eyesight question already mentioned. The form also includes a general declaration that the applicant does not suffer from any other disease or disability which would make him a danger as a driver. When this form has been filled up and signed, the next step depends on Subsection (2) of Section 5. Certain diseases or disabilities having thus been specified on the declaration form, "if from the declaration it appears that the applicant is suffering from any such disease or disability as aforesaid, the licensing authority shall refuse to grant the licence." To these uncompromising words several provisos are attached. One relates to invalid carriages, another to existing motorists, a third proviso gives the refused applicant a right to claim a test. But he can only claim a test where there are no such diseases or disabilities as are prescribed; the prescribed diseases and disabilities here are epilepsy, liability to sudden giddiness or fainting, and inability to read letters and figures as on a car number-plate at 25 yards in good daylight, with glasses if worn. It follows that the eyesight disability is final; if it exists, the licensing authority cannot grant a licence. Subsection (5) gives a right of appeal to a court of summary jurisdiction to "any person who is aggrieved by the refusal of a licensing authority to grant a licence." But the Court of Appeal says this does not mean that a person who is refused a licence on account of the eyesight disqualification can appeal to a court of summary jurisdiction. "It is impossible to hold that he is a person aggrieved by the refusal to grant him a licence when the licensing authority has no alternative but to refuse." The case therefore goes back to the justices in Cumberland with an intimation that they have no power to interfere; the decision of the licensing authority (refusing the licence) must stand. The Master of the Rolls nevertheless observes that the Minister of Transport, who prescribes the questions on the form of declaration of physical fitness, might well "consider whether this question is framed so as to embrace cases where defective eyesight ought to be a ground for refusing a licence to drive a motor-car, and whether it does not—as it stands—cause experienced motor-drivers to be excluded from driving when, if the question was in somewhat different terms, they would be able to satisfy all requirements as to capacity to drive a motor-car." Meanwhile, as Lord Justice Slesser remarked, there is nothing to stop the applicant trying again if he can get glasses which will fit him to read the letters and figures at 25 yards.

Deafness as a Driver's Disability.

Another recent case under the Road Traffic Act turned on the possible disability of deafness. The proceedings were under that part of the Act which relates to the driving of "public service vehicles." The Road Traffic Commissioners had refused a man a licence on the ground of occasional deafness; the magistrate's court at Birmingham allowed his appeal subject to conditions that he should always have a conductor on his vehicle and that he should wear an instrument to aid his hearing. The applicant said he was deaf only when in a quiet room; when in a motor-car, with the vibration of the engine and the noise of the traffic, he could hear perfectly. He could hear passengers speaking to him. Dr. J. S. Crabbe said that the applicant suffered from catarrhal deafness, which meant that he had extreme difficulty in hearing in a quiet room but no difficulty where there was vibration or noise.

BATH ROYAL UNITED HOSPITAL APPEAL.—It is announced that the sum of £100,000 appealed for in order to build the new hospital in Combe Park has now been raised.

DRUGS, SURGICAL INSTRUMENTS, APPLIANCES, AND FOODS.

B.M.A. EXHIBITION AT EASTBOURNE.

(Concluded from p. 266.)

Surgical Instruments and Appliances and Clinical Apparatus.

[9] Adair, Dutt and Co., Ltd. (Mortimer House, 37–41, Mortimer-street, W. 1), representing B. Braun, of Melsungen, showed an improved model Sphygmomanometer in a dark oak case; a Hydrostatic Dilating Set which supersedes the de Ribes' bag, using sterile pig- or sheep-bladders filled with glycerin; and sterile catgut Kuhn, claimed to be an absolutely sterile ligature material of standardised absorption-time and greater tensile strength than other catgut of similar thickness.—[60] Allen and Hanburys, Ltd. (48, Wigmore-street, W. 1), showed their latest model of the St. Bartholomew's Hospital Operating Table, with a new patent self-locking device for the Trendelenburg position and an improved head-flap, designed by Mr. T. P. Dunhill, for goitre operations; the "A. and H." Patent Knife with detachable blades and stainless steel handle; Souttar's latest improved Craniotome; a new Adenoid Plane with removable blades, designed by Mr. O. Popper; the Gastrophotor, an intra-gastric camera [1]; Kirschner's Wire Fracture Extension Apparatus and Mr. Max Page's modified pattern; Chevalier Jackson's Œsophagoscopy and Bronchoscopy instruments; Bayeux's Subcutaneous Oxygen Injection Apparatus; the Suda Bath and Chair for colonic lavage; the London Hospital Chorda Catgut, in which the iodine used is controlled to prevent any reduction of tensile strength, and the London Hospital Ligatures and Sutures.—[42] Antiphlogistine was once more shown as the best-known method for the continuous application of moist heat.—[63] Arnold and Sons (in association with Savory and Moore, Ltd., and John Bell and Croyden, 50–52, Wigmore-street, W. 1) showed the latest model of the Arnold Operation Table, with improved movement for the Trendelenburg position, an instrument-table in stainless steel, a new transformer for heating cautery burners which can be used off any supply, direct or alternating, at any voltage, and is absolutely earth-free; Mr. Frank Harvey's improved Sigmoidoscope and Rectal Speculum [2]; and a complete range of Marylebone sutures and ligatures.—[3] The British Hanovia Quartz Lamp Co. (Slough, Bucks) showed, among their light and heat lamps and accessories, the Duo-therapy unit, embodying in one apparatus the Alpine sun lamp and a Sollux heat lamp; a new combination unit incorporating the super-Kromayer and the standard Alpine sun lamps, and an oto-rhino-laryngological water-cooled lamp which, unlike the Kromayer, can be used in any position and is light to handle.—[35] Campoirette, Ltd. (252, Regent-street, W. 1), showed Camp surgical supports, particularly the patent adjustment on their surgical belt which gives a very light adaptable rigid support.—[8] Cameron's Surgical Specialities, Ltd. (57c, New Cavendish-street, W. 1), gave demonstrations with the Electro-diagnostoset, which is now well known as a complete set of electrically lighted investigation instruments; and the Cauterodyne, a radio-frequency cautery scalpel.—[24] Stanley Cox, Ltd. (39, Gerrard-street, W. 1), showed an efficient and portable Autogram X ray apparatus, which automatically calculates and measures the necessary exposure; and a portable diathermy apparatus weighing only 38 pounds.—[18] H. E. Curtis and Son, Ltd. (7, Mandeville-place, W. 1), demonstrated an entirely new corset-belt, En Mains Croisées, supporting the abdominal wall by three pairs of interlacing elastic straps set obliquely at the front.—[19] C. W. Dixey

[2] THE LANCET, 1931, i., 1033.

and Son, Ltd. (19, Old Bond-street, and 20, Welbeck-street, W.1), amidst a wide range of ophthalmic apparatus, drew attention to their cases of test lenses; the Maddox, cheiroscope for training children with squint; and the Mackie slit lamp, introduced to provide an efficient, simple, sturdy instrument at moderate cost.—[65] Down Bros., Ltd. (21–23, St. Thomas's-street, S.E. 1), had a full display of surgical instruments, including Howarth's improved Chevalier Jackson's bronchoscopy and œsophagoscopy instruments with recent lens improvements; a complete selection of Meurice Sinclair's operative instruments for fractures, and new fracture instruments by Mr. Souttar; ox-bone plates and spoons by Hamilton Bailey; the up-to-date Quadrant model operation table with several important recent modifications, including an oil-pressure pump, and diathermy cautery knives and endotherms.—[25] The Dowsing Radiant Heat Co., Ltd. (91–93, Baker-street, W. 1) announced that their well-known heating apparatus can now be purchased outright or hired for long periods, and also showed the Dexter home washing machine, which uses only a quarter of a unit an hour.—[20] Fassett and Johnson, Ltd. (86, Clerkenwell-road, E.C.), together with their usual range of adhesive plasters, drew special attention to the new Ready-aid, combining a sterilised gauze pad, medicated with boric acid, attached to a strip of flesh-coloured adhesive plaster, ventilated to allow filtered air to reach the wound.—[13] The Genito-Urinary Manufacturing Co. (28A, Devonshire-street, W. 1), the sole agents for J. Eynard et Cie, Paris, and for Stilles, Stockholm, showed, among many instruments, new laryngoscopes, bronchoscopes and œsophagoscopes by V. E. Negus; empyema drainage-tubes by A. Tudor Edwards; Kidd's new model automatic boomerang stitcher; the diathermy knife, and radium instruments.—[1] The Holborn Surgical Instrument Co., Ltd. (26, Thavies Inn, E.C. 1), emphasised the advantages of their new twin-pump operation table fitted with a pedal whereby the surgeon can produce the Trendelenburg position without using his hands; Stutzer's patent surgeon's stool, on which the surgeon sits in a comfortable saddle and can tilt himself forward by a foot lever; the Brilite tongue spatula, with a lamp in the handle, reflecting light along the specially polished glass tongue-depressor; the Protector uterine forceps, which seize the cervix without lacerating it, and which can be hooked into the Schonenberg self-retaining speculum; and an improved form of Simpson's lithotomy straps in the form of canvas boots so that the legs are not cut.—[29] Johnson and Johnson (Great Britain), Ltd. (Slough, Bucks) displayed a range of ligatures, sutures and other appliances, including the well-known "K. Y." jelly; the Tek toothbrush, with a small head to get inside the dental arch; and Johnson's baby products. [49 and 61] Mayer and Phelps (59–61, New Cavendish-street, W.1) had a large selection of instruments and appliances on view, including the M.P. clinical lamp designed for the obstetric wing of University College Hospital—a useful lamp for general examinations; Lambert Roger's skull plough with electric motor; Prof. D. Dougal's new model for teaching obstetrics to a class—a porcelain sink with basin shaped like the posterior half of the uterus; and an improved breast pump in which the milk is drawn through a wide aperture into the bottle, which is boilable.—[23] Rayner and Keeler, Ltd. (100, New Bond-street, W. 1), among their display of ophthalmic instruments, drew attention to their full range of retinoscopes and ophthalmoscopes; the Edridge-Green colour perception lantern and bead-box test; the internally illuminated drum test type, and a luminous object perimeter-scotometer. [14] A halometer and a tonsil suction apparatus by Dr. F. C. Eve, and an inhaler for open ether administration by W. Stanley Sykes.—[52] Short and Mason, Ltd. (Aneroid Works, Walthamstow, E. 17), in addition to the familiar Tycos sphygmomanometers and thermometers, showed the Tycos venostat for blood shunting—throwing a substantial part of the blood out of the general circulation—in heart failure and cardiac asthma; the Tycos dermatherm, for accurate measurement of surface temperatures, and apparatus for tubal insufflation.—[40 and 41] T. J. Smith and Nephew, Ltd. (42, Tavistock-square, W.C. 1), presented Elastoplast, an elastic adhesive strapping which is already a favourite treatment for varicose ulcers and veins, and many sprains and other injuries; and also Cellona, an entirely new plaster-of-Paris bandage which is light and clean, somewhat elastic and easily cut, and which can be completely moistened in plain water in a few seconds.—[80] Edward Taylor, Ltd. (Salford, Lancs), showed their range of adhesive and medicated plasters, including Flexoplast, a self-adhesive antiseptic elastic bandage; Emergoplast, a simple dressing for immediate application to minor injuries, which is supplied with various medications, with and without perforation, full spread or part spread; and zinc oxide plaster spread on white wool felt of three different textures.

Books.

[12] Baillière, Tindall and Cox (7 and 8, Henrietta-street, Covent Garden, W.C. 2) were showing "Quantitative Clinical Chemistry," by J. P. Peters and D. D. Van Slyke; "Bioassays," by J. C. Munch; "Annals of the Pickett-Thomson Research Laboratory," Volume VII.; "Leonardo Da Vinci," by J. P. McMurrich, and some new volumes in the Students' Aids Series.—[39] J. and A. Churchill, Ltd. (40, Gloucester-place, W. 1), drew attention to Bowlby and Andrewes' "Surgical Pathology and Morbid Anatomy," revised by Geoffrey Keynes; Rogers and Megaw's "Tropical Medicine"; Romanis and Mitchiner's "Surgical Emergencies"; Osgood and Haskins' "Text-book of Laboratory Diagnosis"; and to a number of new volumes in the "Recent Advances" series, which now numbers 28, notably Gray's "Allergy," Beaumont's "Medicine," now in its sixth edition, Findlay's "Chemotherapy" and Imms's "Entomology."—[6] Constable and Co., Ltd. (10 and 12, Orange-street, W.C. 2), had on their stand "The Practical Treatment of Diabetes," by T. Izod Bennett; "The Metabolism of Tumours," by Otto Warburg; "The Social Control of the Mentally Deficient," by Stanley Powell Davies; and "The Modern Medical Monographs" series.—[21A] The Food Education Society (29, Gordon-square, W.C.1) displayed a number of books and pamphlets on diet and domestic subjects, including "Children's Diet," by Charles Hecht; "Vegetables: Their Use, Abuse and Neglect"; "Life without Servants," by Harold Begbie, and "The Truth about Fat."—[43] H. K. Lewis and Co., Ltd. (136 and 140, Gower-street, W.C. 1), pointed out "Diseases of the Tongue," by W. G. Spencer and Stanford Cade; "The Physical and Radiological Examination of the Lungs," by James Crocket; "The Alcohol Habit and its Treatment," by W. E. Masters; "Fundamental Principles of Ray Therapy: An Elementary Text-book for Nurses, Students and Practitioners," by William Beaumont; "A Text-book on the Nursing and Diseases of Sick Children," edited by Alan A. Moncrieff, and also many varieties of *medical stationery*.—[31] The Oxford University Press (Amen House, Warwick-square, E.C.4) selected for special recommendation C. B. Heald's "Injuries and Sport: A General Guide to the Practitioner"; Hurst and Stewart's "Gastric and Duodenal Ulcer"; new editions of Ker's "Infectious Diseases," Still's "Common Disorders and Diseases of Childhood," Wright's "Applied Physiology," and Price's "Text-book of the Practice of Medicine," "Bibliotheca Osleriana," and William Brown's "Science and Personality."

Spas, Hospital Furniture, and Miscellaneous.

[5] Buxton showed photographs of their hot and natural baths and therapeutic establishment, pointing out that a "cure ticket" for a period of three

weeks, covering all treatments prescribed, can be obtained for three guineas.—[32] R. H. Dent (309, Oxford-street, W. 1) showed further developments of his Ardente hearing aids, particularly the new "snug" type of earpiece which fits into the orifice without getting hot; and the new stethoscope for deaf doctors, smaller than the original but more sensitive. Ardente auditorium sets are now installed in many churches.—[21] The Eastbourne Gas Company (87–89, Terminus-road, Eastbourne) showed photographs of practical uses of gas in hospitals; an incinerator; and the Indusa heater for large apartments.—[75] General Acoustics, Ltd. (77, Wigmore-street, W. 1), showed Acousticon aids for the deaf, including electrical and non-electrical apparatus, and the Dime earpiece, which is moulded to the exact shape of the ear.—[27] Harrogate, in drawing attention to its great diversity of spa waters, stressed the mud (Fango) treatment given from a recently discovered bed in the medicinal water-bearing strata, and also the system of training and certification of nursing staff.—[2] Hoskins and Sewell, Ltd. (Bordesley, Birmingham), showed beds, cots and fracture apparatus, particularly the St. Bartholomew's patent wind-up mattress cot, which can be wound up at either end, or the whole mattress can be raised to waist-level for demonstration purposes; the wheeling ward beds have several cunning devices so that a bed can be wheeled in any direction; Hoskite wheels and the Hoskins patent high-pressure lubrication make wardwork simpler, and Goldex and Silvex are pleasing modern metallic finishes for nursing-home or nurses'-home beds.—[71] Kolynos Incorporated (Chenies-street, W.C. 1), presenting their familiar dental cream, drew attention to liquid Kolynos as a mouthwash or spray and Kolynos denture powder for artificial teeth.—[64] The Medical Insurance Agency (B.M.A. House, Tavistock-square, W.C. 1) was represented by officials ready to give advice on all matters of insurance, and reminded visitors of the large grants given by this agency to medical charities every year. An innovation on this stand was the presence of the manager of the B.M.A. (Tavistock-square) branch of the Westminster Bank, who gave information about stocks and shares, wills, trusts, settlements, and other banking matters.—[10] The Medical Sickness, Annuity and Life Assurance Society, Ltd. (300, High Holborn, W.C. 1), had their usual stand to remind visitors that there is an insurance society managed by doctors for doctors.—[16] Pepsodent Co. (8, India-street, E.C. 3) displayed their well-known acid dentifrice.—[38] "The Practitioner" (6–8, Bouverie-street, E.C. 4) was a newcomer to the exhibition; particular attention was invited to the July special number on fractures and accidents.—[26] Thermega, Ltd. (51–53, Victoria-street, S.W. 1), showed electrically heated cushions and blankets and couches, with special reference to a warmed couch-mattress which does much to encourage muscular relaxation.—[50] Whitfields Bedsteads, Ltd. (109 to 125, Watery-lane, Bordesley, Birmingham), invited interest by their Lawson Tait patent cardiac bedstead as designed for Sir Thomas Lewis at University College Hospital; Lawson Tait Barnet maternity bedstead with basinette, as designed for the Wellhouse Hospital, Barnet; and the new Meurice Sinclair's patent portable fracture apparatus for fixing to any bedstead. Also displayed on this stand was the Harco sponge-rubber mattress, a great improvement on the old water-bed or air-bed, with a loose cover made of acid-proof waterproof sheeting which can be removed for sterilisation (Cassell, Andrews and Co., Ltd., Hardman-street, Manchester).

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1930 statistics of six boroughs:—

Name of district and estimated mid-year population.*	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality in childbirth.
Swindon (62,020) ..	15·7	10·8	0·84	1·56	1·0	2·6	63/43	20	2·1
Cambridge (60,730) ..	12·5	11·2	0·61	1·37	1·4	1·7	40/28	28	5·3
Gillingham (56,670) ..	14·8	11·1	1·00	1·77	1·0	2·6	41/22	—	6·2
Poole (56,150) ..	16·7	12·4	0·96	1·87	1·4	2·2	58/35	20	5·3
Watford (55,870) ..	15·4	9·5	0·84	1·48	0·8	1·9	46/33	—	2·3
Darwen (37,780) ..	11·6	12·5	0·26	1·56	1·7	2·5	70/39	—	6·8

Registered stillbirths per 100 live births: Swindon 4·3, Gillingham, 3·6, Poole 4·0, Darwen, 5·5.

* As a rule the estimate (R.-G.) for 1929 has been used.

Swindon.

Dr. Dunstan Brewer says that, although the year 1930 was a healthy one for the country as a whole, it was not so in Swindon. Infant mortality was high; the general mortality was no better than in recent years, and certain diseases were more prevalent than usual and showed a higher fatality. The chief events of 1930 were the reconstruction of the administrative block at the isolation hospital; the building of an adequate maternity hospital; the opening of a new wing of the Victoria Hospital; and the decision to proceed with a scheme for an additional water-supply from Latton. The higher infant mortality-rate was due to neonatal deaths at one period, the deaths subsequently being low. The mortality-rate among pre-school children was also low, but at the school age the rate was unfavourable. All deaths under 20 were made the subject of inquiry, where the medical history of the person was known to the health department. There were 124 such deaths, and of these 11 were due to congenital defects, 7 to measles, 11 to whooping-cough, 9 to diphtheria, 9 to rheumatic infection, and 24 to prematurity. Dr. Brewer adopts the unusual custom of making epidemiological forecasts, which are printed in the health committee's minutes month by month. These forecasts, some of which prove to be right and some wrong, are founded on a study of the local behaviour of disease and its variations in type and of the position of the disease in other parts of the world. Dr. Brewer is hoping that in the future it may be possible to forecast the behaviour of disease as accurately as that of the weather. There were 100 cases of true diphtheria with the high case-fatality of 9 per cent. Both deaths due to and notifications of non-pulmonary tuberculosis, other than meningitis, were higher than usual. Dr. Brewer believes that the higher notifications are in part due to the notifications of enlarged glands found during abdominal operations. He is not satisfied that we are *getting a grasp* of tuberculosis, and suggests that elaborate registers have confused the issue. He welcomes the latest Tuberculosis Order (1930).

Under the Housing Act programme 500 new houses are to be erected, 50 of which will be allocated to rehousing persons displaced by closing or demolition orders. Housing in Swindon is exceptionally good for an industrial town. The amount of overcrowding is not great but does not diminish. The chief hospital lack is for general medical cases, although the new wing at the Victoria Hospital provides some beds for this purpose.

Cambridge.

Dr. Andrew J. Laird says that inhabited houses number 16,215. The five-year housing programme provides for 260 new houses per annum to be erected by the corporation, of which 60 are to be set aside for tenants selected by the health committee from houses demolished and in need of substantial renovation, and from overcrowded houses, in which the tenants cannot pay the rent of a council house and where there are families of young persons. The applicants for municipal houses at the end of 1930 numbered 1511. Caravan dwellings have increased in number during recent years. They are provided with pail closets and stand on unpaved surfaces. Dr. Laird suggests that it may be necessary to provide special parking places, with all necessary requirements, and to prohibit caravans elsewhere. The scheme of Mr. W. B. Grandison, the public dental officer, for the enrolment of mothers and young children to secure regular attention to their teeth continues to grow. During the year 80 mothers took advantage of the treatment offered during pregnancy, and 380 children under school age, an increase of 66 on the previous year, were enrolled, and will be examined and treated every six months or oftener. Mr. Grandison finds that the regular and frequent application of ammonical solution of nitrate of silver and formalin by Howe's method is particularly efficacious in preventing the progress of dental disease in pre-school children.

Gillingham.

Dr. William A. Muir says the shortage of houses is undoubtedly less acute but that about 6 per cent. are overcrowded, according to the standard of two adults per bedroom. The prospects of demolishing unfit properties are better now than for many years. Gillingham, being a town of recent origin, has no slum areas, and its five-year programme only deals with individual unfit houses. At the last census inhabited houses numbered 10,859, and the requirements for the next five years are set down as 600 houses for the relief of overcrowding, 120 to replace demolished houses, and 800 for increase of population. Overcrowding in most cases is due to the shortage of houses, and not to inability to pay the rents of available houses. It has been found more satisfactory in Gillingham to deal with housing defects under the Public Health Acts rather than under Section 3 of the Housing Act, 1925. A local Bill is being promoted to prohibit tents, vans, sheds, &c., from being placed on any land without the previous approval of the corporation.

The corporation now supervises children boarded out under the Children Act, and at the end of the year there were 24 registered foster-mothers, one of whom was fined for failure to notify that she had received a foster-child. In October the borough took over the supervision of midwives. The appointment of Dr. Meta Dunlop as a full-time assistant has enabled antenatal clinics to be established, which were attended by 75 new cases during the last half of the year. The council has also approved the giving of contraceptive advice in cases where pregnancy would be detrimental to health. To begin with, there will be no regular clinic, but appointments will be made for attendance at special sessions at one of the centres. In the spring of 1930 a nuisance arose, which had only been partially remedied when Dr. Muir's report was written, from a new process adopted by a cement factory, resulting in an increased emission of dust in the neighbourhood.

Poole.

Dr. R. J. Maule Horne's report shows that Poole is growing rapidly. At the 1921 census the houses numbered 9400, and since then 4562 houses have been built. Over three miles of new water-mains were laid during 1930, and the sewer extensions have difficulty in keeping pace with the house building. In 1926 there were 400 cesspools; the figure rose to 781 in 1928, and has decreased in 1930 to 662. This exceptional rate of development is a menace to the pine-clad areas, and Dr. Horne is anxious that no tree be sacrificed unnecessarily. About 30 years ago the first blades of rice grass (*Spartina Townsendii*) were found in the harbour, and now some square miles are covered by it. It is an excellent binder for low-lying foreshore land. Poole is well off for parks and swimming facilities. The cleansing and scavenging systems are being reorganised, and it is intended to adopt the Bradford system of controlled tipping. One of the needs is a model lodging-house, which would cater for the visiting seamen.

The public analyst, Mr. William Partridge, reports that the town is badly served in the matter of butter. Well-made butter contains between 10 per cent. and 13 per cent. of water. Of 15 samples analysed during the year, 13 contained from 14·8 per cent. to 16·0 per cent. of water, and of the other two samples one contained 13·6 per cent. and may have been a dairy butter, while the other contained 14·3 per cent. and might be a factory butter or a badly made dairy butter. A huge traffic is done, says Mr. Partridge, in buying dry butter and incorporating water to the maximum, but there is no power to take action, even if it is known that the butter is weighted with water. The municipality took over the supervision of boarded-out children on April 1st, and there are 63 boarded-out children on the register. A table given by Dr. Horne shows that since 1907 the deaths of pre-school children have declined in number even more than the infant deaths.

Watford.

Dr. William J. Cox's report shows that there were 9944 houses at the census of 1921, and that the borough has conducted an active municipal housing campaign since 1916. The slums are grouped around the High-street. Some of the worst have been demolished. In 1924 the Ministry sanctioned the building of 114 houses on the Wiggenhall estate for slum tenants. All the tenants did not accept the offer, and this enabled 114 houses to serve for 152 demolished during 1924 to 1928. It is intended to deal with 199 houses in clearance areas and one other house during the next five years, and it is hoped to deal with at least 130 during the present year. In addition, 400 houses are to be built to relieve shortage. The Watford Joint Isolation Hospital (66 beds) is inadequate for the population of 100,000 which it serves. Dr. Cox urges strongly that the diphtheria ward, for which plans have been drawn, should be proceeded with at once. Dr. Cox inspects most of the schools in his district on behalf of the county council. He shows that, owing to the tact and energy of the school nurse in following up, nearly all the parents obtained treatment for the defects found in their children, and that there has been a very great improvement in the cleanliness of the children since the early days of medical inspection.

Darwen.

Dr. James Robertson gives cotton-weaving, paper-making, fireclay- and iron-workers as the chief occupations. Trade is depressed, and the population is estimated to have declined by 1000 since the 1921 census. There is no hospital accommodation in the borough for any but infectious diseases. The Queen's Park Hospital, Blackburn, is the public assistance infirmary for Darwen. General medical and surgical cases are admitted to Blackburn Royal Infirmary. The only common lodging-house is a municipal one. Owing to trade depression and the decrease in the number of vagrants, due to the Unemployment Insurance Acts, there was a decline in lodgers of about 12 per cent., and 15 aged and infirm lodgers were admitted to the public assistance institution. The clearance of the Bury-street area is now practically complete, and, apart from this, there are only small groups of scattered houses requiring to be demolished. Dr. Robertson says that the majority of the ground floors of existing houses are flagged, and that the chief trouble is dampness owing to the lack of subsoil drainage. It is estimated that during the next five years 243 houses will be repaired under Part II. of the Housing Act, 1930.

There are 73 cowkeepers on the register, and extensive improvements have been carried out at the dairy farms, at an estimated cost of about £2000. The bed of the River Darwen is held to be a nuisance, owing to the deposit of rubbish. The whole of the bed needs pitching and the portion near dwelling-houses and shops should be culverted.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 25TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 36 (last week, 50); scarlet fever, 1526; diphtheria, 838; enteric fever, 59; pneumonia, 521; puerperal fever, 43; puerperal pyrexia, 94; cerebro-spinal fever, 30 (last week, 43); acute poliomyelitis, 10; acute polio-encephalitis, 1; encephalitis lethargica, 9; continued fever, 1; dysentery, 7; and ophthalmia neonatorum, 106. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 28th–29th was as follows: Small-pox, 58 under treatment, 2 under observation (last week, 62 and 2 respectively); scarlet fever, 1231; diphtheria, 1513; enteric fever, 13; measles, 138; whooping-cough, 396; puerperal fever, 30 (plus 9 babies); encephalitis lethargica, 208; poliomyelitis, 1; "other diseases," 124. At St. Margaret's Hospital there were 10 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 1 (0) from enteric fever, 18 (1) from measles, 2 (0) from scarlet fever, 13 (3) from whooping-cough, 19 (3) from diphtheria, 39 (11) from diarrhœa and enteritis under two years, and 14 (1) from influenza. The figures in parentheses are those for London itself.

Five of the deaths from measles were reported from Barnsley and four from Liverpool. Three fatal cases of diphtheria were notified in Liverpool, which also reported five deaths from diarrhœa and enteritis under two years. Of the other deaths from this cause four were in Sheffield, three in Sunderland, and two in West Hartlepool. Three deaths from meningococcal meningitis were notified in London, one in an infant, and the others in age-groups 15–35.

The number of stillbirths notified during the week was 247 (corresponding to a rate of 36 per 1000 births), including 42 in London.

PANEL AND CONTRACT PRACTICE

POSITION OF NATIONAL HEALTH INSURANCE.

DEBATE IN HOUSE OF COMMONS.

An important debate on sickness certification and other problems of national health insurance took place in the House of Commons on July 29th, arising out of a vote of £13,116,212 for salaries and expenses of the Ministry of Health.

Sir **Kingsley Wood** (formerly Parliamentary Secretary to the Ministry of Health) said he wished to draw attention to certain grave and disturbing aspects of national health insurance, and particularly to the very heavy sickness and disablement experience which had now prevailed for a considerable period. This matter was not only of national importance, but was giving considerable anxiety to the societies themselves and to all who desired to see national insurance maintained on a safe and stable basis. The system had proved of great use and worth to the nation. The total amount paid out in the last year for which they had figures, including the Exchequer contribution from the Ministry of Health Vote, was some £35,000,000, and medical benefit cost some £8,700,000. Of that sum insurance doctors received some £6,256,000, and nearly £2,000,000 was paid to insurance chemists for drugs and appliances. There was paid in sickness benefit some £11,250,000, in disablement benefit some £5,350,000, and in maternity benefit another £1,440,000. The decline in the mortality-rate had been one of the most satisfactory features of the century. Medical science had progressed a long way in recent years; many diseases had been successfully grappled with, and a very great deal had been attained by medical research. Yet in spite of this there had been a marked and striking increase in claims of insured persons for sickness and disablement benefits and in the consequent expenditure on those benefits. This process had been going on since 1925, and while there was some improvement in 1928, as compared with the high rate of 1927, this improvement was not maintained. Last year there was some improvement, though not a very considerable one, but in 1929 there was a serious epidemic of influenza, and, therefore, not much encouragement could be drawn from the figures for 1930. No one who had studied the subject would say that the problem was by any means solved, or that further immediate steps were not urgently needed.

A DISQUIETING SITUATION.

There were three grave and arresting factors in the present situation. The first was the adverse experience which the approved societies had suffered and the claim experience in respect of married women. In fact, the societies had been affected so seriously that the valuers in some instances, quite recently warned the societies that unless conditions improved to a marked extent the whole of the present surplus would be exhausted within a few years in providing ordinary benefit. A number of societies which specially catered for married women would have to cancel their additional benefit schemes—a very serious step indeed. Already a number of societies had cancelled such schemes. The Government actuary, in his report to Parliament a short time ago, stated that the claims of unmarried women had risen by 60 per cent. so far as sickness benefit was concerned, and the claims of married women had risen by 106 per cent. As regards disablement benefit, Sir Alfred Watson stated that the claims of unmarried women had risen by 100 per cent., and those of married women by 159 per cent. Another very curious feature was this: that among males it was the younger insured persons rather than the older whose burdens cast upon the approved societies had increased in recent years. The third factor was that the excessive claims, as far as a large proportion of insured persons were concerned, were more in the North of England than in the South. The following figures, which had been presented to the Ministry of Health, were very extraordinary and illuminating in regard to causes of incapacity: Excess per cent. of the northern area over the southern area—rheumatism, 50; nervous and mental disorders, 41; digestive disorders, 21. These were remarkable and difficult things to explain. Obviously, in connexion with a very large proportion of the population, unemployment and bad health must be considered contributory factors, but let no one think that this great increase of claims was due to deterioration in the national health. This was borne out by the Minister of Health himself. Could anything be done to prevent what was the real danger of the national health insurance system degenerating into an unfortunate position similar to that of the unemployment insurance system?

Since the House last discussed this question the Minister of Health had taken two very important steps in the right direction. He had endeavoured to strengthen the safeguards to be adopted by societies in connexion with the supervision of claims, and he had very strongly urged on approved societies the importance of maintaining an efficient system of sickness visitation; and, secondly, an early reference to the regional medical officers for examination of claims. The Minister had also taken certain steps with respect to the medical profession, and he (Sir Kingsley Wood) was in agreement with him there. Some advice, and, if necessary, some reminder, was required in that connexion. An amending regulation had been made with regard to change of doctor. That change had been made for obvious reasons, and he thought that anyone who had been associated with approved society administration during the last two or three years would agree that the change was very necessary. He asked the Minister whether he proposed to take further steps. Useful and desirable as the steps that he had taken might be, it was difficult to feel confident that sufficient had been done to rescue the national health insurance system from its present position.

NEED FOR HIGHER STANDARDS.

Mr. **Rhys Davies** said that up to date the approved societies had lost a sum of £25,000,000 as a result of the economy Act passed by the Conservative party. That would be sufficient to put all the societies in a sound financial position. Sir Kingsley Wood had made no criticism of the medical profession, and had also avoided dentists, opticians, and surgical appliance makers, all of whom seemed to have their eyes keenly fixed on the funds of approved societies. Sir Kingsley Wood was inclined to blame the 17,000,000 insured persons. He (Mr. Davies) hoped to prove that some of the blame rested with other people. He was satisfied that the standard of honour in relation to claims from the insured population, from the medical profession, the dentists, the opticians, and so forth, must be raised and improved, otherwise the scheme would ultimately fail in its objects. There was something fundamentally wrong in the relationship between the medical profession, the Ministry of Health, and the approved societies. There was no doubt at all that some members of the medical profession issued certificates that were absolutely unjustifiable. He had reason to pay tribute to the high skill and genius of the medical profession in this country, but this high skill did not enter into their business and administrative work. He thought that it should be brought home to the doctors the amount of damage that might be done to the funds of approved societies by the issue of certificates which ought not to be issued. The same remark applied to the dental officers. He had come to the conclusion that there was no way out of these difficulties until the doctors were in some way employed by the State.

EFFECT OF THE DEPRESSION.

Dr. **Morris-Jones** said that the excessive claim for sickness benefit under the national health insurance system was probably, apart from the deficiency in the unemployment insurance fund, the most serious matter with which Parliament and the Government had to deal at the present time. He was convinced that there was a tendency among all classes of the population, insured and others, to get as much as they possibly could. The next great factor was the serious economic position in the world, and especially in this country, and the unemployment position. It was not possible for a man who was a long time out of work to be really healthy. He was not now engaged in panel practice, but he had a long experience of it, and he considered that one great cause of the present position under this scheme was the economic depression which was affecting the physical and mental health of the insured population. If the House agreed with that view they would not agree that the medical profession, in the circumstances, was so much to blame. There was no more difficult problem before the profession at the present time than this question of sickness claims among insured persons, and its members were as alive to their responsibilities as the approved societies. There was one cause of the increase of sickness claims among women—namely, that a woman might still be able to do housework in her home, although she had been certified as incapable of following an outside occupation. From many years' experience he knew that very often, where a certificate had been given showing that a woman who was insured was not fit for an occupation in which she was insured, she was engaged in household work which in many cases would be as arduous as the occupation in respect of which she was receiving benefit. How that was to be dealt with was a problem, but it was responsible for a great deal of leakage under the national insurance system. He did not think that an inspector of an approved society should be allowed to dissect and analyse medical certificates, but he suggested that the Ministry of Health should state categorically that no insurance certificate should be accepted for such a thing as a cold or a chill. The phraseology of certificates should be more specific in character.

THE MINISTER'S MEMORANDUM.

Mr. **Meller** congratulated the Minister on the issue of memoranda, both to the approved societies and to the medical profession, which dealt very faithfully and frankly with the situation with regard to national health insurance. He (Mr. Meller) approached this subject with the very deepest respect for the medical profession, and there was no need for the medical profession to be troubled because the Minister had come to the conclusion that the state of affairs demanded some explanation. He thought the Minister was justified in bringing to the notice of the medical profession some of the results of the experiments and examinations which had been made, and in asking them to see whether there was something inherently wrong in the system itself, or whether there was something wrong with the health of the people of the country. Very nearly £9,000,000 was spent on medical treatment and medicines for the insured population. That was a vast sum to be spent on some 15,000 medical practitioners who came under the Act. Therefore they were entitled to ask this honourable profession that they should give a service worthy of the profession, with full honesty and due regard to the insured persons. Reference had been made in the debate to some of the causes of incapacity stated on medical certificates. There was loose certification certainly among some members of the profession, and quite recently he saw a certificate which contained the initials "I.D.K.," which he believed meant "I don't know." When a professional gentleman descended to that sort of thing there was cause for complaint.

Miss WILKINSON: Does the hon. Member object to the medical profession being honest occasionally?

Mr. MELLER said that he should have said that the certificate was hardly honest, and a little misleading, because he only surmised that "I.D.K." meant "I don't know." There was another certificate in reference to a person incapable of work for some weeks, stating that he was suffering from abrasion of the ribs, and it appeared that during the time he was upon the funds he engaged in a heavyweight boxing contest, and laid out his opponent in the fifth round. That sort of thing was, of course, unsatisfactory, but he did not claim that it was a typical sample of what was being done. On the contrary, very excellent service was given by the medical profession as a whole. He hoped the Minister would join in an exhortation to the medical profession to try and find out the cause of the present situation, and see whether it was in fact due to the bad health of the people or to something else.

In 1922, in England and Wales, 113,000 cases were referred for examination, and the figures gradually rose until, in 1930, 531,000 cases were submitted. Of the cases submitted for examination in 1922, 40 per cent. were found to be still incapable of work; 60 per cent. of the cases declared off, either because they did not attend for examination, or were found by the medical referee to be capable of work. One would have thought, if certification was going on in the very best way, that, as they began to increase the number of references, the number of persons found incapable of work would be increased also, and that those capable of work would have become less. But that was not so. When 531,000 persons were referred for examination only 34 per cent., as against 40 per cent. in 1922, were found incapable of work. The statements by the Minister in his Memorandum were a serious and grave indictment, whether against the insured person, the medical profession, or the approved societies. He was not attempting to lay a charge at the door of any one of the three, but it should go out from the House of Commons with a very loud voice that something had to be done to repair this state of things. It was not only a reflection on the medical profession, but a reflection upon the moral honesty of the people. If there was a good and honest reason for these things then they ought to know it, and he was sure that the Minister of Health would be only too glad to withdraw the allegations contained in the Memorandum. Arising out of the examinations, one thing stood out pre-eminently—namely, that the increase in the sickness experience was greater among married women than any other class. If married women stood alone their scheme would be insolvent. This matter had been considered by a body outside, and they stated that if the scheme with regard to married women was to be put upon a satisfactory basis, and married women were to be accepted as an insurance proposition, there were three courses open—namely, to increase the contributions to meet the risk, or to reduce benefits, or to deal with the matter somewhat on the lines of the present system; that was to say, when a woman married she must pass out of insurance, and if she subsequently entered the employment market, she must requalify for benefit. During the time of requalification a limited sickness and maternity benefit would be provided. He hoped the Minister would consider that particular point. Another point which deserved the attention of the Minister was the effect of a high sickness experience and a low contribution record. They could not keep the societies on a solvent basis if they put upon them the responsibility of providing full benefits while their contributions were declining. He hoped the Minister would do something to meet that situation. Apart from the drain upon the funds of approved societies through a sickness experience greater than had been expected, there was no more important matter to consider than the position of those persons who, if no assistance was forthcoming from the Government, would find their health insurance in jeopardy.

RESPONSIBILITIES OF THE PROFESSION.

Mr. THOMAS LEWIS said he thought the medical profession would say that a good deal of the increase of sickness was due to the reduced stamina of the people. Unless there was a marked change in our economic conditions the sickness experience would become worse, and, therefore, it was exceedingly important that societies should retain all their funds. His complaint was that the Ministry were endeavouring to force societies to adopt methods of sickness visitation and do work which the doctors would say was work which they alone ought to do. Except in rare instances, it should be the duty of the panel doctor to decide whether a person was entitled to be on the funds or not. He asked the Minister at the earliest possible moment to restore the amount which was stolen from the approved societies by the last Government.

Mr. PALMER said that panel practitioners ought to feel no less than the administrators of approved societies their responsibility for establishing the soundness of the health insurance scheme. He would like to feel that the medical profession were helping to prevent any "monkeying about" and people getting benefits to which they were not entitled. There was a difference between a doctor's certificate to establish a pensions claim and a type of certificate in respect of a claim for benefit under an approved society. It seemed to him that the medical profession could do, under the terms of certification, exactly what one was prepared to pay them well enough to do. He urged that every measure of coöperation should be tried before they got to the point of cutting benefits.

Miss RATHBONE said she would like to put forward one explanation of the excessive claims of married women. In every time of depression in industry it was the married woman who felt the pinch. The decreased state of health of married women through that cause was one of the reasons for the increase in their claims.

Miss SUSAN LAWRENCE (Parliamentary Secretary to the Ministry of Health) said Miss Rathbone was right when she said that times of unemployment and stress pressed most hardly on the mother in the home. She thought Mr. Meller was a little hard on the medical gentlemen to whom he had referred. The doctor who wrote "I.D.K." on the certificate was a person she regarded with some liking. It was very much the same thing as when a general practitioner said that he required a second opinion. She was certain, knowing a little about the society to which Mr. Meller had referred, that if the certificate came in it was received in exactly that sense, and that a second medical opinion was hurried to the bedside of the patient. It was the business of the Ministry of Health to try to assimilate all the various points of view. After long and careful reports the Ministry had come to the conclusion that, making every allowance for the effects of unemployment and depression, the whole of the sickness claims made on approved societies could not be altogether accounted for by those causes. The last circular was sent out by the Ministry on May 31st last, and the Ministry was holding conferences with the approved societies. It was rather early to suggest any further measures. The central fund was not in a very good position. It reached a maximum of over £1,500,000, but it had since been seriously depleted owing to the necessity of making grants to societies who were in a deficiency through causes beyond their control. That was a serious matter, and the financial position of the fund was engaging the earnest attention of the Minister. It was possible that a levy might be one of the subjects to be discussed, but that was a matter for further consideration. She could not give any more definite information at the moment. With regard to the third valuation, a number of societies had found their disposable surplus reduced, and some of them had been compelled to curtail additional benefits previously provided. The financial basis of the insurance scheme would have the careful attention of the Minister in the near future. With regard to the prolongation of insurance, the Ministry was now in conference with the approved societies and the Minister hoped to be able to announce a decision very soon on the matter.

MORE DRASTIC STEPS.

Sir T. **Inskip** said he was sorry that Miss Lawrence was not able to give the Committee a little more guidance. A question which she did not wholly face was what the Minister was going to do about the present position. He had called attention to the necessity or desirability of doctors being, perhaps, a little more careful, but the position called for something more definite and more drastic than a mere suggestion of that sort. Mr. Rhys Davies had suggested that the doctors should be brought more in touch with the consequences of their certificates, and that they should be made to realise how much money depended on the grant of a certificate. He (Sir T. Inskip) was not sure that that was the right way to enable the doctors to do their duty. A doctor should use his medical skill by addressing his mind to the condition of the patient, and not by considering what might be the consequences, great or small, of granting a certificate. The hon. Member had also suggested that the medical service should be nationalised. He did not believe that any doctor in the House would agree with the proposal, and he did not envy the task of the Minister of Health if such a proposal were ever adopted. Two other proposals which had been made were rather more helpful. One was that a little more attention should be given to sick visitation, and the other was that the operation of the regional medical staff should be speeded up. He was sorry to hear Miss Lawrence say that a levy upon the central fund was under grave consideration. The result of such a levy would be to make the good societies pay for the lax administration of the bad societies. The central fund existed for well-defined purposes, and the Minister ought to be quite certain that he had exhausted all the possibilities of improving the administration of the societies in relation to claims before he allowed any such levy.

PATIENTS' GRIEVANCES.

Sir E. **Graham-Little** said he wished to make an earnest appeal to the Minister to reconsider certain points of prime importance. They ought to make the medical service under national health insurance approximate as closely as possible to the conditions of private practice. The latest regulation in regard to the change of panel doctor was seriously disliked by the medical profession, and a unanimous resolution was passed at a representative meeting protesting against that particular restriction. The psychological effect of a free choice of doctor could hardly be overestimated, and he was sure that the Minister had not considered that aspect sufficiently. It was one of the facets of the problem which would be disastrously affected by a State medical service. He asked the Minister to give his attention to the difference in the treatment between private and insured persons, represented by the limitations of panel prescriptions. He hoped the Minister would be prepared to revise the agreement made in 1927. The Minister should not be too severe on panel practitioners who were trying to give as good a service to panel patients as to their private patients, and were being penalised for doing it. Dissatisfaction by insured persons and by the public generally with the National Health Insurance Act was a real thing, and one of the indications of it was the enormous rise in the number of attendances at voluntary hospitals during the last 12 years. A great proportion of his own patients were dissatisfied with their treatment under the panel doctors, and at the hospital with which he was associated the figures showed that the patients included a large proportion of insured persons. His experience was confirmed by the figures of other hospitals. His own hospital dealt with 50,000 out-patients last year, and he believed a similar number was dealt with at Guy's Hospital. There was no doubt that many of the reasons for the dissatisfaction with the national health insurance system could easily be removed. Lord Hewart had described the Minister of Health as a pure despot; he (Sir E. Graham-Little) invited him to exercise his despotism in rectifying these defects.

ECONOMY AND EFFICIENCY.

Lieut.-Colonel **Fremantle** said it was the desire and the determination of the whole House to maintain the efficiency of the health services within the limits of the exhaustable purse. There was far too great a tendency to think that the real progress of expansion must be in bricks and mortar. In this time of straitened finance the Minister was not necessarily reducing progress if he tried to make the most use of the services which already existed. He asked the Minister what was being done to make use of the voluntary hospitals in the combined scheme under the Local Government Act of 1929? It might be necessary one day to have an official hospital service, but he did not believe it, and he hoped not. At the present time in the interests of the sick poor, and owing to the exhausted purse, he asked the Minister, while it was not too late, to see that officialdom met voluntaryism, and that opportunities were provided for their combination.

THE MINISTER'S REPLY.

Mr. **Greenwood** (Minister of Health), replying to the debate, said that Sir T. Inskip wanted more attention paid to sick visitation. Half the complaints made to-day were to the effect that there was too much. Again, he suggested that there should be greater use of regional medical officers. That also had been one of the complaints. There had been on some sides of the House, perhaps, a little too much emphasis on improper insurance claims. There was not the slightest doubt that there were improper claims. He would gladly sweep all those people out of benefit, but they had to be careful that in tightening their administration they were not denying just claims. Improved administration and greater coöperation between all the agencies concerned were having a very substantial effect. In 1930 the total expenditure of all approved societies on sickness and disablement benefit was £2,000,000 less than in the previous year. It might be that 1930 was a lighter year for sickness, but he thought part of that saving was undoubtedly due to improved administration and to more effective coöperation between the panel doctors, the regional medical officers, and the approved societies. The improvement of last year had continued during the first half of this year, and the sickness claims for the quarter which had just finished were the lowest for any quarter for several years past; so that the steps that had been taken were now beginning to prove effective.

In reply to Sir E. Graham-Little, he might say that they had not got rid of the free choice of doctor. They had partly limited the rapidity with which an insured person could run from one doctor to another. That had been done in the interests of the medical profession, as well as in the interests of the insured persons, and the Ministry stood by that action. He was satisfied that in the long run it would be found to be in the interests of the medical profession. In connexion with institutional services there was a conflict of opinion between the doctors and the approved societies. There was a reasonable working scheme which, while it did not completely satisfy everybody, was working pretty well.

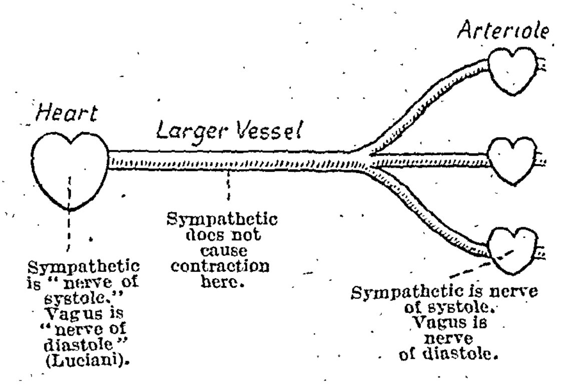
CORRESPONDENCE

VASCULAR PERISTALSIS.

To the Editor of THE LANCET.

SIR,—I was much interested in your reference to my book, "The Hearts of Man," in your annotation (p. 254) on Vascular Peristalsis. The book was read by the late Sir James Mackenzie, to whom I had the honour to be assistant for a number of years. He would neither accept nor reject my findings, but agreed with me that no explanation which entirely satisfied him had been given of the so-called dicrotic waves.

You say in your annotation: "It is difficult to conceive of a peristaltic wave which could travel at the same rate as the pulse, while if it did not do so a pulse tracing should show two different and asynchronous waves." It was my contention that this is exactly what pulse tracings do show. They show (1) the main wave caused by the contraction of the left ventricle, and (2) smaller waves called dicrotic or post-dicrotic, which, I suggested, are really peristaltic waves in the vessel wall and not waves set up by the closure of the aortic valves. I tried to explain myself by reference to the bowel where, when peristalsis is active, the sphincters are open in inhibition and where, when the sphincters are active—i.e., shut—peristalsis is inhibited, and would therefore not be seen in a tracing. The heart was recognised by Gaskell as a sphincter, and is innervated like the other sphincters. The innervation of the larger arteries seems, on the contrary, to be similar to that of the bowel between the sphincters, *until the arterioles are reached*, when a similar innervation to that of the heart is encountered. I visualised these arterioles, therefore, as so many small sphincters or "hearts" acting in unison (synchronously) with the heart itself. The accompanying diagram illustrates the mechanism. These findings were arrived at by a very prolonged study of polygraph tracings, all of which were submitted to Sir James Mackenzie. The work of Luisada, to which you refer, certainly seems to lend support to these ideas.



Arteriole
Heart
Larger Vessel
Sympathetic does not cause contraction here.
Sympathetic is "nerve of systole." Vagus is "nerve of diastole" (Luciani).
Sympathetic is nerve of systole. Vagus is nerve of diastole.

I am, Sir, yours faithfully,

July 30th, 1931. R. M. WILSON.

TOXIC EFFECTS OF INTRAVENOUS SALYRGAN.

To the Editor of THE LANCET.

SIR,—In his article in your issue of July 18th Dr. C. T. Andrews attributes the symptoms observed by him in one case immediately following the intravenous injection of salyrgan to the toxic effects of the drug. May I venture to suggest that these symptoms were not due to the salyrgan, but to the intravenous injection, per se, in an individual whose cardiovascular system and water-balance were already very much at fault? One experiences symptoms of similar nature occasionally after the administration of almost any kind of intravenous injection. Some years ago, when engaged in studying the effect of isotonic, hypertonic, and hypotonic solution upon the water-balance, I sometimes saw similar effects from small quantities of distilled water. My personal experience with salyrgan dates from its first introduction, and I have never seen any unfavourable results, although I well remember toxic effects, and even death, after novasurol. The symptoms in these cases were those of acute mercurial poisoning. May I mention that I always give salyrgan in its original concentration, without further dilution by distilled water?

I am, Sir, yours faithfully,

Weymouth-street, W., July 30th, 1931. O. B. BODE.

VEHICLES FOR CHEMICAL CONTRACEPTIVES.

To the Editor of THE LANCET.

SIR,—The annotation in your issue of August 1st encourages me to report the progress made since the publication of the article to which you refer. During the last few years, under the auspices of the Birth Control Investigation Committee, I have tested the spermicidal powers of many foaming tablets and cocoa-butter suppositories. I have found foaming tablets the more spermicidal, with both human and guinea-pig sperms. Now many clinical workers consider cocoa-butter suppositories more reliable than foaming tablets. A few insoluble substances (e.g., stearin and paraffin) have been said to be harmful to certain micro-organisms and sperms, if placed in the same dish.[1] This phenomenon, however, will not account for any contraceptive action of cocoa-butter, for sperms are extremely active in glass vessels containing this fat, if suspended in suitable fluids. As is pointed out in your annotation, it must be supposed that the contraceptive action of cocoa-butter is due to its forming a film over the cervix, which acts as a mechanical barrier to sperms. This mechanical barrier, which is not tested in my experiments, may be very important.

---

[1] Drzewina, A., and Bohn, G.: Compt. rend. de l'Acad. des Sci., 1927, clxxxv., 875.

There is, however, one great disadvantage in cocoa-butter. I have shown that it hinders the action of chinosol and quinine bisulphate in a remarkable way, so that their effect upon sperms is much reduced. A new fat has now been tried as a vehicle for chinosol. This is a proprietary preparation called cocoala. I find that this fat does not hinder the action of chinosol on sperms. The contraceptive value of insoluble vehicles is now being studied under the Birth Control Investigation Committee. If, as seems likely, cocoala is found to have the same mechanical effect as cocoa-butter, it is obviously preferable. It has the further advantage of being very nearly odourless.

The experiments were carried out by throwing one suppository into 7·5 c.cm. of guinea-pig sperm suspension, maintained at the temperature of the body, and estimating the activity of the sperms after a quarter of an hour. Maximum activity is recorded as 3+, and no movement whatever as 0. The other signs indicate intermediate degrees of activity. No experiment is recorded unless the control sperms show an activity of 3 or 3+. The more effective suppositories were further tested by substituting one-tenth for a whole one. Three or four experiments were performed with each suppository at each concentration. They are arranged below in the order of their spermicidal powers, beginning with the most spermicidal.

—	One suppository to 7·5 c.cm.	One-tenth suppository to 7·5 c.cm.
Grs. 3 chinosol in cocoala	0 0 0 0	2 2 2 3
Grs. 1½ " " "	0 0 1 1	3 3+ 3+
Grs. 3 " " cocoa-butter ..	1+ 3 3 3+	—
Grs. 5 quinine bisulphate in cocoa-butter	2+ 3 3 3	—

The superiority of cocoala as a vehicle for chinosol is evident.

I may add that a new large foaming tablet called Kontrol gives the best results of any yet tested by the guinea-pig sperm technique. Not the slightest movement of a single sperm was seen in six experiments at the concentration of one-tenth of a tablet to 7·5 c.cm.

I am, Sir, yours faithfully,
JOHN R. BAKER.

Department of Zoology and Comparative Anatomy,
University Museum, Oxford, August 3rd, 1931.

MORTALITY AFTER PROSTATE OPERATIONS

To the Editor of THE LANCET.

SIR,—Mr. J. Swift Joly, in your issue of July 18th puts very clearly the importance of the pre- and post-operative treatment in relation to prostatectomy, but he also compares general anæsthesia with spinal slightly to the disadvantage of the latter. He says that spinal anæsthesia is ideal from the surgeon's point of view; it gives complete relaxation and makes the operation easier than any other form of anæsthetic. With this I entirely agree, but he adds that it has certain disadvantages to the patient, the most important of these being a fall of blood pressure which increases the risk of reactionary hæmorrhage and seriously diminishes the urinary excretion during the first 24 hours after operation. In my experience these disadvantages need not appear under spinal anæsthesia by the combined method. The 402 consecutive cases of prostatectomy under spinal anæsthesia which I reported in your issue of June 27th were mixed hospital and private cases. The total mortality was just under 5 per cent., and if the purely accidental deaths, in which the cause of death had no relation whatever to hæmorrhage, diminished urinary secretion or uræmia from infection be excluded, the mortality is just under 4 per cent. The following is the technique I use for this combined form of anæsthesia:—

Nitrous oxide and oxygen, A.C.E. and oxygen, or ether and oxygen is given, the drug being chosen according to the particular case. The anæsthesia is carried to unconsciousness, not surgical anæsthesia. An intrathecal injection is then given in the second lumbar space of either 0·02 g. of stovaine or 0·04 g. of novocaine in normal saline. The finest needle now in use must be used or the dose will not be sufficient. Relaxation of the lower abdominal wall will be *obtained*. The operating table must be kept in a slight slope, head downwards, all the time. When the patient is moved from the theatre this slight slope should be maintained on the trolley, and he should be placed in bed with blocks already under the foot of the bed. When the patient is back in bed the blood pressure will be found to be approximately the same as before the operation, and there will be no increased risk of reactionary hæmorrhage or diminished urinary secretion. I am authorised by Mr. Sydney Macdonald to say that "in employing spinal anæsthesia in accordance with the above technique there is less hæmorrhage at the time of operating, as with the relaxation obtained one is less liable to get outside the proper line of cleavage, less reactionary hæmorrhage, no shock, and less interference with urinary secretion afterwards."

Quite lately I had to anæsthetise two big men, both very fat, aged 75 and 78, respectively. The physicians in charge of these cases vetoed any form of inhalation anæsthesia because of the extreme amount of emphysema and chronic bronchitis present. The first case was given 0·035 g. stovaine by the fine needle; the second was given 0·04 g. by a slightly larger needle. Both made uninterrupted recoveries.

I am, Sir, yours faithfully,
H. M. PAGE.

Blandford-street, W., August 4th, 1931.

A BARNSLEY CONVALESCENT WARD.—Lady Sutherland last week opened a convalescent ward at the Beckett Hospital, Barnsley, which has cost about £600, and is the gift of the Wharncliffe Woodmoor Colliery owners and workmen.

NORTH DEVON INFIRMARY.—Last year this Barnstaple Hospital (72 beds) received 824 in-patients, who stayed on an average 21 days, and cost an average of £7 4s. 3*d.* each. Of the 1423 out-patients 544 were accident and emergency cases.

WAKING OF PATIENTS IN HOSPITAL.—The Minister of Health has issued a memorandum to all county and county borough councils drawing attention to the report on patients' waking hours in London voluntary hospitals, published by King Edward's Hospital Fund for London, and suggesting that the councils will no doubt wish to consider the question of adopting the recommendations in the administration of their own hospitals.

to panel patients which would be given to private paying patients and which treatments were in general use in private medical practice: and what were the reasons for this prohibition.—Mr. GREENWOOD replied: I am not aware of any such regulations as my hon. friend mentions. Insurance practitioners are required in all ordinary cases to give to their patients all proper and necessary medical services other than those involving the application of such special skill and experience as is not to be expected of general practitioners as a class, and to order or supply such drugs and prescribed appliances as are requisite for the treatment of any patient.

Health Insurance Benefit and Rheumatic Diseases.

Mr. GRAHAM WHITE asked the Minister of Health the approximate amount of national health benefit paid in any recent years in respect of sickness arising from rheumatic diseases.—Mr. GREENWOOD replied: The information desired by the hon. Member is not available and could only be obtained as the result of a special investigation and return by every one of about 7000 approved societies and branches. It has, however, been estimated on good authority that one-seventh of the total invalidity amongst insured persons is due to rheumatic diseases, and on this basis the cost involved for the year 1930 would have been about £2,500,000.

Cost of Dental Benefit.

Mr. THOMAS LEWIS asked the Minister of Health if he would lay upon the Table a statement of the expenditure of the Regional Dental Service and the Dental Benefit Council, showing the cost of establishing the organisation, the number of cases dealt with, and the running expenses.—Mr. GREENWOOD replied: I will bring my hon. friend's request to the notice of the Dental Benefit Council.

Patent Rights of a Dental Process.

Mr. BUCHANAN asked the Minister of Health his reason for refusing to accept the offer of Dr. Watson, of 2, Third-avenue, King's Park, Glasgow, to give his department the patent rights of a process for extracting, disinfecting, and replanting teeth, and a machine for the purpose of boring and tapping teeth; and whether he was aware that America had accepted the patent rights.—Mr. GREENWOOD replied: I have not considered it desirable to take advantage of Dr. Watson's offer because, as has been explained to him on several occasions, his proper course is to follow the customary practice of making full scientific publication of his methods and results, with a view to trial and criticism by his professional colleagues. I have no information on the second part of the question.

FRIDAY, JULY 31ST.

Telephone Instruments and Hygienic Precautions.

Mr. WOMERSLEY asked the Postmaster-General whether he was aware that the new type of hand-microphone instrument, for which an extra rental was charged, could not be taken to pieces for cleaning, and if he would take action to enable cleaning to be done to avoid unhygienic conditions that might otherwise arise.—Mr. VIANT (Assistant Postmaster-General) replied: It is not necessary to take telephone instrument to pieces in order to maintain it in hygienic condition. Dismantling is very liable to dama the delicate parts of the instrument, and it is undesirab to facilitate such action.

MEDICAL NEWS

University of Cambridge.

On July 28th the following degrees were conferred:—

M.D.—*R. W. B. Ellis, * J. E. D. Crozier, E. E. Llewellyn, A. E. Naish, W. D. Newcombe, and A. W. Spence.

M.B.—*R. H. B. Snow.*

B. Chir.—H. S. Buckland, W. A. Fell, C. R. T. Lane, *E. H. W. Lyle, R. G. Orr, P. G. Scott, H. C. Stewart, and J. W. Summerhayes.

* By proxy.

Royal College of Physicians of London.

At a meeting of the College on July 30th with Lord Dawson, the President, in the chair, the following Fellows of the College were elected officers for the ensuing year:—

Censors: Dr. James Collier, Dr. W. Langdon Brown, Dr. C. R. Box, and Sir Charlton Briscoe. *Treasurer:* Dr. S. P. Phillips. *Registrar:* Dr. Raymond Crawfurd. *Harveian Librarian:* Dr. T. H. Arnold Chaplin. *Assistant Registrar:* Dr. Robert Oswald Moon. *Library Committee:* Dr. H. R. Spencer, Dr. C. J. Singer, Dr. Anthony Feiling, and Dr. J. D. Rolleston. *Curators of the Museum:* Dr. H. R. Spencer, Dr. Hugh Thursfield, Dr. S. E. Dore, and Dr. Harold Gardiner-Hill. *Finance Committee:* Dr. Robert Hutchison, Sir Percival Horton-Smith-Hartley, and Dr. L. S. T. Burrell.

The following were elected Examiners:

Chemistry: Mr. H. W. Cremer and Mr. W. B. Tuck, D.Sc. *Physics:* Mr. D. Orson Wood and Mr. F. L. Hopwood, D.Sc. *Practical Pharmacy:* Prof. J. A. Gunn, Dr. W. E. Dixon, Dr. Philip Hamill, Dr. Newman Neild, and Dr. Orlando Inchley. *Physiology:* Prof. Joseph Barcroft, F.R.S., and Prof. R. J. S. McDowall. *Anatomy:* Prof. Duncan Blair. *Pathology:* Dr. C. E. Lakin, Dr. George Graham, Prof. Matthew Stewart, and Dr. H. W. C. Vines. *Medical Anatomy and Principles and Practice of Medicine:* Sir Thomas Horder, Dr. A. E. Russell, Dr. Cecil Wall, Dr. David Forsyth, Dr. E. A. Cockayne, Dr. Reginald Miller, Dr. E. P. Poulton, Dr. Albert Ramsbottom, Dr. A. C. D. Firth, Dr. E. Bellingham Smith, Dr. L. S. T. Burrell, and Dr. Ivor J. Davies. *Midwifery and Diseases Peculiar to Women:* Mr. J. P. Hedley, Mr. J. B. Banister, Mr. D. W. Roy, Prof. Daniel Dougal, and Mr. A. C. Palmer. *Public Health:* (Part I.) Dr. G. Roche Lynch. (Part II.) Dr. G. F. Buchan. *Tropical Medicine:* Dr. J. A. Arkwright, F.R.S., and Dr. N. Hamilton Fairley. *Ophthalmic Medicine and Surgery:* Dr. T. Grainger Stewart. *Psychological Medicine:* (Part I.) Dr. Edward Mapother. (Part II.) Dr. J. G. Porter Phillips, and Dr. S. A. K. Wilson. *Gynæcology and Obstetrics:* Prof. J. M. Munro Kerr. *Laryngology and Otology:* Mr. Lionel Colledge. *Murchison Scholarship* (1932): Dr. Theodore Thompson and Dr. O. L. V. de Wesselow.

The following Fellows were elected members of the Advisory Committee to the President:—Dr. H. Morley Fletcher, Dr. Robert Hutchison, Dr. A. M. H. Gray, Dr. H. L. Tidy, Dr. H. H. Dale, Dr. J. A. Ryle, and Dr. T. Watts Eden.—Dr. James Collier and Dr. W. Langdon Brown were appointed to represent the College on the Mackenzie-Mackinnon trust committee, and Sir Humphry Rolleston was re-elected representative on the executive committee of the Imperial Cancer Research Fund.—The President, Lord Dawson, will represent the College at the celebrat of the 250th anniversary of the Royal College of Physic of Edinburgh.

The President announced that he had appointed George Newman to be Harveian Orator and Dr. Dug Baird to give the Bradshaw lecture, both in 1932. (T forthcoming Harveian oration in October next will delivered by Dr. Robert Hutchison).—In addition to t appointments to Lectureships announced at the last meetin Miss Harriette Chick, D.Sc., was appointed Oliver-Sharp lecturer and Dr. L. P. Jacks the Lloyd Roberts lecturer fo 1932.

The Baly medal, awarded every alternate year to t person who shall be deemed to have most distinguish himself in the science of physiology during the two years immediately preceding the award, was awarded to Prof W. B. Cannon of Harvard University. The President also announced the award in Edinburgh of the Murchiso scholarship jointly to W. M. Arnott and R. J. Kellar.

The following candidates, having satisfied the Censors' Board, were admitted Members of the College:

Wilbert Hurst Brown, M.B.Oxf., Ernest Thomas Conybeare, M.B.Lond., Edward Philip Nagle Creagh, M.B., N.U.I., Hugh Crichton-Miller, M.D.Edin., Ratansha Dinsha Dalal, L.R.C.P., Courtenay Nisbet Evans, M.B.Lond., Joseph Hayes Fairweather, M.D.Edin., Mohamed Gamil Farid, M.B.Cairo, Theophil Johannes Friedrich Frank, M.D.Melb., Clifford Allchin Gill, L.R.C.P., Thomas Howard Gillison, M.B.Edin., John Howell Halliday, M.B.Sydney, Henry Procter Hutchinson, M.B.Camb., Harold Gordon McGregor, M.B.Lond., Robert Michael Maher, M.D.Lond., John Onbridge Mercer, M.B.N.Z., Herbert Leslie Milles, L.R.C.P., Wilfrid George Oakley, M.B.Camb., Rupert Samuel Bruce Pearson, M.B.Oxf., Evelyn Nora Popper, M.D.Lond., Mostyn Levi Powell, M.B.Melb., Gangandram Venkataswami Ram Mohan, M.B.Madras, Douglas Riding, M.D.Liverp., William Carey Smallwood, M.B.Birm., Tej Raj Swarup, M.B.Lucknow, L.R.C.P., Abd El Kader Talkhan, M.B. Cairo, Alfred Brian Taylor, M.B.Birm., Geoffrey Fawsitt Taylor, L.R.C.P., Thomas Tennent, M.D.Glasg., Hugh Ferguson Watson, M.D.Glasg., Charles Edward Walton Wheaton, M.D.Lond., and Bertram Alan Young, M.D.Lond.

Diplomas of L.R.C.P. were conferred upon 140 candidates (120 men and 20 women) who have passed the Final Examination of the Conjoint Board and complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

A. M. M. Ali, Bombay and Middlesex; E. Anthony, London; Grace M. Archer, Westminster; H. G. E. Arthure, Charing Cross; Doris Ascough, Manchester; P. T. Ashby, Camb. and London; E. S. Asiedu-Ofei, Birmingham; E. J. Baldwin, Oxford and St. Thomas's; A. V. Baliga, Bombay and King's Coll.; K. Baxter, Manchester; R. A. Beazer, Oxford and St. Thomas's; W. D. Bell, Camb. and St. Bart.'s; W. H. Bradbeer, Guy's; R. J. B. Broad, Middlesex; G. O. Brooks, Camb. and St. Mary's; J. M. L. Burtenshaw, Oxford and Guy's; C. R. Caffry, Dublin and London; Beatrice L. Campion, Royal Free; A. M. Cantor, Guy's; P. Chandra, Punjab and Cambridge; E. F. Claridge, London; Barbara G. C. Clarke,

R. C. Coben, and C. P. Collins, Univ. Coll.; J. G. Connell, Camb. and Sheffield; H. A. Constable, Guy's; A. B Cook, St. Bart.'s; E. J. Currant, Camb. and London; D. Davidson, Univ. Coll.; V. S. H. Davies, M.B. Liverpool; J. R. Duffield, Camb. and Westminster; S. Durham, Oxford and London; K. V. Earle, Camb. and St. Thomas's; G. G. M. Edelsten, Oxford and St. Bart.'s; G. R. Ellis, Camb. and Liverpool; E. St. J. C. Emerson, St. Mary's; L. S. Everett, Camb. and King's Coll; P. B. Fernando, L.M.S. Ceylon, Univ. Coll.; G. A. Fleet, M.D. McGill; M. J. Garber, Guy's; H. N. Garrns, Camb. and Guy's; V. Glass, Univ. Coll.; S. Goide, Charing Cross; C. E. D. H. Goodhart, Camb. and St. Bart.'s; G. H. Gool, Guy's; W. H. Greany, Oxford and Guy's; H. F. Green, Camb. and St. Bart.'s; A. Greenberg, St. Bart.'s; H. J. Griffiths, Middlesex; Hilary S. M. Hadaway, Royal Free; Winifred S. Hall, Univ. Coll.; H. A. R. Hamilton, St. Thomas's; D. C. Harris, Middlesex; A. E. T. Hart, Camb. and St. Thomas's; E. S. Harverson, Univ. Coll.; J. R. Heming, St. Thomas's; E. Hinden, Camb. and St. George's; L. C. Holland, Bristol; J. H. Hughes, M.B. Liverpool; Blaguigna Illitch, Royal Free; N. M. James, Camb. and King's Coll.; J. E. Jenkyn-Thomas, Camb. and St. Bart.'s; W. P. Jenson, Camb. and Westminster; D. Johnson, Bristol and King's Coll.; Annie L. Jones, Univ. Coll.; Esther P. W. Jones, Cardiff and Charing Cross; Alice M. Kaye, King's Coll.; C. A. Keane, St. Bart.'s; Mary L. R. Kennard, and S. J. Knight, St. Mary's; M. Kosloff, Guy's; L. Lamb, Cardiff and Guy's; J. S. Lane, L.M.S.S.A. Camb. and Guy's; P. R. K. Lane, Birmingham; A. M. P. Laurent, Univ. Coll.; H. G. Letcher, M.B. Adelaide; T. M. A. Lewis, Cardiff and London; H. L. Lightstone, Middlesex; M. A. Lloyd, St. Bart.'s; J. W. McLaren, Camb. and St. Thomas's; J. W. Macmillan, Camb. and St. Thomas's; G. A. M. Madel, Middlesex; W. Meanley, Sheffield and Leeds; E. K. K. Menon, Birmingham; A. K. Monro, Camb. and London; P. B. Moroney, M.B., Liverpool; W. J. Morris, Liverpool; I. Moshinsky, Guy's; H. C. Muirhead, Guy's; R. W. C. Murray, Camb. and Birmingham; T. F. B. Noble, London; L. G. Norman, Univ. Coll.; Catherine O'Connor, Manchester; Angela M. S. A. enheim, King's Coll.; Lily M. O'Hanlon, King's Coll.; G. F. etty, St. Bart.'s; A. L. Potter, M.B. Liverpool; Eluned M. uleston-Jones, Royal Free; J. Rabinovitch, Leeds; G. F. ees-Jones, Univ. Coll; D. Y. Richardson, Durham; J. C. oberts, and H. D. Robertson, St. Bart.'s; C. H. Rogerson, Guy's; N. L. Rusby, Oxford and St. Thomas's; P. C. Sanyal, M.B. Calcutta, Middlesex; M. N. Sardena, M.B. Punjab, Schrire, M.B. Cape Town; E. Sharpe, Camb. and Guy's; W. H. Shawcross, Camb. and King's Coll.; M. H. Sherwell, M.B. Birmingham; Rosalie Shoenberg, Royal Free; A. B. mmons, King's Coll.; H. Simmons, St. Bart.'s; H. Singh, M.B. Punjab, St. Bart.'s; J. C. Smith, M.B. Manchester; G. Snell, St. Thomas's; R. G. W. Southern, St. Thomas's; dys M. G. Spencer, Camb. and King's Coll.; Violet Spiller, M.D. Geneva, Royal Free; A. A. Sreenivasan, Bombay and Charing Cross; T. Standring, King's Coll.; C. Starkie, Manchester; Swaminathan, Bombay and Manchester; R. A. Sykes, Camb. and St. Bart.'s; A. K. Talkhan, M.B. Cairo, G. Tattersall, Manchester and Univ. Coll.; Winifred P. Thomas, Univ. Coll.; F. Townsend-Coles, London; J. G. Vincent-Smith, Camb. and St. George's; A. B. Water, Camb. and St. Bart.'s; J. H. ay, Leeds and Middlesex; G. Wells, St. Bart's; M. Westwood, Camb. and St. Bart.'s; S. O. Widman, St. Thomas's; E. W. M. Williams, Cardiff; Dorothy Woodman, Royal Free; S. L. right, Univ. Coll.; A. H. Zair, Camb. and Birmingham; Zeitlin, London.

The undermentioned diplomas were conferred jointly with the Royal College of Surgeons upon the following candidates:—

D.T.M. & H.—E. S. Adderley, B. P. Baliga, C. J. H. Brink, A. Burnett, R. Caldera, H. P. Chaudhuri, H. D. Cronyn, B. R. sa, C. H. Howat, A. J. Johnson, F. B. Khambatta, R. K. Khanna, P. B. Lee Potter, H. W. H. McClelland, S. H. Moore, Ethel Morris, J. L. Razdan, J. A. Rosset, V. Sivalingham, M. Syddiq, J. Taylor, P. G. G. Unnithan, L. A. F. Wiles, W. Williams, W. E. S. Winn.

D.O.M.S.—M. Basheer, G. H. B. Black, M. G. J. Booysen, A. Brew, Eleanor M. P. Brock, C. Budeiri, A. Campbell, Franks, A. W. Green, E. G. Kennedy, Edith G. Limmex, Macky, K. C. S. Menon, Catherine E. Orr-Ewing, B. W. Roffey, K. Saha, R. Sampson, M. N. Sardana, R. C. Tarapore, L. St. V. Welch.

D.P.H.—L. W. Cann, Irene E. Chandler, Anne A. Craig, J. Crawford, M. B. Daver, T. W. Davies, D. M. de Silva, D. Diamond, C. F. Dolman, M. J. Evans, T. I. Evans, Sarah P. M. Griffiths, C Hill, Kathleen M. Horton, J. E. Haward, Amy L. Jagger, A. B. Kettle, Catherine B. McArthur, Hilda K. McKernan, J. Portelly, J. F. Southward, T. W. Stallybrass, R. Stuart, R. J. Toleman, Olga F. Tregelles, E. W. Vaughan, Nora W. Wamsley.

D.P.M.—G. J. Bell, L. J. Bendit, A. Cannon, C. R. Cooke-Taylor, J. A. F. Denyssen, S. B. Hall, J. G. Hamilton, S. D. Isaacs, J. M. Loftus, Joyce McConnell, G. W. Murray, C. J. Thomas, L. M. Webber.

D.L.O.—G. E. Archer, M. G. J. Booysen, E. E. L. Burnier, G. V. Joglekar, B. V. P. Reddy.

Royal College of Surgeons of England.

An ordinary meeting of the Council was held on July 30th with Mr. R. P. Rowlands, vice-president, in the chair.

Diplomas of Membership were granted to the candidates whose names appear elsewhere as new licentiates of the Royal College of Physicians. Diplomas in Tropical Medicine and Hygiene and in Ophthalmic Medicine and Surgery were also granted jointly with the College of Physicians.

On the nomination of the Canadian Medical Association, Dr. J. C. B. Grant, professor of anatomy, and Mr. C. H. Best, professor of physiology, were appointed assessors for the Primary Examination for the Fellowship to be held in Toronto next October.

University of London.

At recent examinations the following candidates were successful:—

M.D.

Branch I. (Medicine).—Ilahi Bakhsh, and Philip Berry, Guy's Hosp.; Alexander Cohen, London Hosp.; Dorothy Collishaw, London (R.F.H.) Sch. of Med. for Women; G. I. Davies, Univ. Coll. Hosp.; R. P. P. Davies, St. George's Hosp.; Archibald Gilpin, King's Coll. Hosp.; M. L. Mistri, Guy's Hosp.; Mary E. Pease, Univ. Coll. Hosp.; G. C. Pether, Middlesex Hosp.; David Preiskel, St. Bart.'s Hosp.; J. H. Simmons, and G. E. F. Sutton, King's Coll. Hosp.; C. E. W. Wheaton, St. Thomas's Hosp.; E. A. Wood, and B. A. Young, Univ. Coll. Hosp.

Branch II (Pathology).—J. N. Cumings, King's Coll. Hosp.

Branch III. (Psychological Medicine).—F. E. E. Schneider, Univ. Coll. Hosp.

Branch IV. (Midwifery and Diseases of Women).—Harriet E. Acheson, London (R.F.H.) Sch. of Med. for Women; D. A. Blount, St. Bart.'s Hosp.; Bridget S. P. Gurney, and M. R. Jones, London (R.F.H.) Sch. of Med. for Women; Joyce Morgan, Westminster Hosp.; K. I. Parkes, King's Coll. Hosp.; and T. B. Pearce, St. Thomas's Hosp.

Branch VI. (Tropical Medicine).—R. V. Bowles, Univ. Coll. Hosp.; and G. P. Patel, Grant Med. Coll. Bombay, and London (R.F.H.) Sch. of Med. for Women.

M.S.

Branch I. (Surgery).—Mark Coleman and R. S. Pilcher both of Univ. Coll. Hosp.

Branch IV. (Laryngology, Otology, and Rhinology).—A. G. Tresidder, London Hosp.

Forthcoming Lectures.—Three lectures on the Production, Distribution, and Value of Milk will be given by Prof. R. Stenhouse Williams, M.D., at the London School of Economics on Wednesdays, Oct. 14th, 21st, and 28th at 5 P.M.—Prof. K. Bühler, who occupies the chair of psychology in the University of Vienna, will give three lectures on the Theory of Language and the Psychology of Speech, at University College on dates in October to be announced later.—The Semon lecture will this year be delivered by Mr. Douglas Harmer, F.R.C.S., on Thursday, Nov. 5th, at 5 P.M., in the rooms of the Royal Society of Medicine, Wimpole-street, W. His subject will be the Relative Value of Radiotherapy in the Treatment of Cancer in the Upper Air Passages.

The *William Julius Mickle Fellowship*, of the value of at least £200, is offered to the graduate who has, in the opinion of the Senate, done most to advance medical art or science within the preceding five years. Applications must be made before Oct. 1st, and particulars are obtainable from the Academic Registrar.

Society of Apothecaries of London.

At recent examinations the following candidates were successful:—

Surgery.—K. W. Bruce, Univ. of Durham; G. B. Carter, Univ. of Manchester; M. Ditton, Univ. of Heidelberg and Royal Free Hosp.; A. A. Grace, St. Bart.'s Hosp.; B. N. Halder, Univ. of Durham; R. Schauder, King's Coll. Hosp.; and C. F. Williamson, Univ. of Birmingham.

Medicine.—H. W. Davies, St. Mary's Hosp.; G. R. Germany, Univ. of Sheffield; A. R. Madden, St. Mary's Hosp.; O. L. Matthews, Univ. Coll. Hosp.; and M. R. Tuteur-Samuel, Universities of Freiburg and Manchester.

Forensic Medicine.—O. A. P. Clark, Westminster Hosp.; R. R. Clipstein, St. Mary's Hosp.; G. Handelsman, Univ. of Witwatersrand and London Hosp.; O. L. Matthews, Univ. Coll. Hosp.; C. Morgan, Charing Cross Hosp.; M. S. Mules, Royal Free Hosp.; and Grantley Smith, Univ. of Bristol and Guy's Hosp.

Midwifery.—G. B. Carter, Univ. of Manchester; Sidney Smith, Univ. of Manchester; and V. M. White, London Hosp.

The following candidates, having completed the Final Examination, are granted the diploma of the Society entitling them to practise medicine, surgery, and midwifery: G. R. Germany, A. R. Madden, O. L. Matthews, R. Schauder, M. R. Tuteur-Samuel, and C. F. Williamson.

Scottish Conjoint Examining Board.

The final examinations of the Board of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, have just concluded at Edinburgh. Out of 91 candidates entered the following 29 have been granted the diplomas of L.R.C.P. Edin., L.R.C.S. Edin., L.R.F.P. & S. Glasg.:—

Genesis Ameratunga, Sirisena Petiyagoda, T. F. Kirkpatrick, H. J. Smith, H. T. Anthonisz, T. A. M. Ashforth, G. L. Whitton, C. F. W. de Saram, B. A. Armitage, M. W. Joseph, L. J. Goggins, R. J. F. L. Talbot, C. M. Douglas, G. W. Purlmannasinghem, S. R. Iyengar, Samuel Grasse, F. A. Ebert, A. M. C. Stephenson, I. M. Sclare, J. A. Walsh, Wilfred Kelly, Maxwell Smellie, S. V. Rajah, M. E. Rubin, A. G. Williams, G. D. Morgan, P. A. V. Pillai, H. F. Ezzat, and Simon Freeman.

Paddington Green Children's Hospital.

The Duke of Connaught last week opened a new convalescent home at Lightwater, near Bagshot, for this hospital. It has cost £5000.

NOTES, COMMENTS, AND ABSTRACTS

HEALTH IN WEST AFRICA.

THE latest vital statistics[1] of non-native officials in West Africa (comprising Gambia, Sierra Leone, Gold Coast, and Nigeria) show that the average number in the service has risen continuously from about 1200 in 1903 to over 4000 in 1930. At the same time the crude death-rate has fallen from 20 to 5·3 per 1000, the lowest point yet reached. The "invaliding"-rate shows a similar fall from 65 per 1000 in 1903 to 11 per 1000 in 1930. Of the 23 deaths in 1930 very few were due directly to tropical diseases, while of the 49 cases of invaliding five are attributed to malaria and one to blackwater fever. The largest group, numbering 11, are classified as neurasthenia, and the figures suggest that the risk of mental breakdown exceeds the risk of physical disablement from diseases peculiar to the tropics, and the environmental problems involved deserve attention. The form of the report has been somewhat altered from that of previous years. The data are now given separately for male and female officers, and new comparative tables have been introduced summarising the rates per 1000 of deaths and invalidings in each of the four territories over a period of 20 years. The difficulty in interpreting these tables, and in using the information relating to females, lies in the small numbers of persons involved. The improvement that has taken place in each territory and in the area as a whole would be far more clearly seen if standardised death-rates could be incorporated. The crude rates, however, suggest a vast improvement in the health conditions of the service during the last quarter of a century.

DIPHTHERIA IN A PARIS HOSPITAL.

IN a recent communication to the Academy of Medicine at Paris, Dr. B. Weill-Hallé[2] recorded his observations on diphtheria at the Hôpital des Enfants Malades in 1929 and 1930. A total of 1210 cases of diphtheria were admitted to the special pavilion at this hospital during this period, and 131 were fatal—a mortality of 10·8 per cent. Ninety-three deaths occurred among 1054 cases of faucial diphtheria (8·7 per cent. mortality), 31 deaths among the laryngeal or laryngo-tracheo-brachial cases (22 per cent.), and there were 7 deaths among 28 cases of paralysis. The mortality was almost the same in each of the two years, being 11 per cent. in 1929 and 10·6 per cent. in 1930. Comparing these figures with those which he reported from the same hospital in 1903, when he was Prof. Marfan's house physician, he shows that there has been a considerable fall in the incidence of diphtheria—mainly, he says, as the result of active immunisation—though the number of severe cases still remains high. This severity he attributes to various causes, such as virulence of the organisms, delay in diagnosis and specific treatment, association with seasonal infections and a special constitution, especially latent congenital syphilis. Although the treatment was the same in the two periods, the present dose of antitoxin was three to four times the amount used in 1901–02. He therefore concludes that diphtheria in 1929–30 was a less fatal disease than in 1901–02 and that diphtheria antitoxin had by no means lost any of its efficacy as some maintained. His present practice is to give an intramuscular injection of antitoxin on admission to hospital in order to neutralise the circulating toxin and at the same time to give a subcutaneous injection which is more slowly absorbed but continues to exercise its antitoxic effect during the following days. In apparently hopeless cases an intravenous injection is given half an hour after the other two injections, and during the next four or five days small doses of antitoxin are administered by the subcutaneous and intramuscular routes.

THE LIGHTING OF OFFICES.

WE noted last week (p. 258) some recommendations of the Council of the Illuminating Engineering Society on the lighting of schools and libraries. A pamphlet on the daylight illumination required in offices is published by the Department of Scientific and Industrial Research.[1] It might be thought that the adequacy of the natural lighting at any point in a room would depend solely upon the actual illumination at that point, so that a room which might seem light enough on a bright day would seem inadequately lighted on a dull day. Some time ago evidence was obtained that this is not so, but that, over a wide range of actual illumination values, the adequacy or inadequacy of the lighting at any given point is closely correlated with the daylight factor at that point. To study this point a "jury" of observers, including architects, illuminating engineers, and others, visited certain rooms in Whitehall and judged the adequacy of the lighting in different parts of the room. The result of the work was the conclusion that lighting in an office is adequate when the daylight factor equals or exceeds 0·2 per cent.—i.e., a sill ratio of 0·4 per cent. This is exactly the figure taken as a minimum of adequate lighting by the committee whose report was noticed last week.

GREAT MEN IN PUBLIC HEALTH.

YET another book[2] inspired by the names of the great sanitarians inscribed on the façade of the new School of Hygiene in Gower-street. There is, perhaps, more to be said than appears at first sight for such institutions giving on busy, noisy streets. Dr. Tobey does not restrict himself (as did M. E. M. Walker in his "Pioneers of Public Health"[3]) to the 21 selected heroes. He ranges over the whole history of public health, and writes accurately and interestingly of the progress of sanitary science from Moses to Gorgas and after. He goes to some extent off the track which has been beaten pretty hard in recent years, and those who are a little bored with Lister, Pasteur, and Florence Nightingale can turn for refreshment to the chapters on W. T. Sedgwick, Trudeau, and the mental hygienists. The book is beautifully produced (except for the binding).

ERRATA.—*In a report of a paper read before the Section of Pathology of the British Medical Association on July 22nd (p. 247) Dr. G. Roche Lynch is credited with a statement that "the employment of a non-medical analyst seriously embarrassed the work of highly skilled men." This misrepresents his meaning; for the point he wished to make was that faulty observation by the medical man at the post-mortem seriously embarrasses the work of the non-medical analyst.*

In an annotation, entitled Sympathetic Ganglion Lesions in Scleroderma, which appeared on p. 255 of our last issue, the name of Dr. Geoffrey Rake was incorrectly given. Dr. Rake, who was formerly resident at Guy's Hospital, is at present working at the Rockefeller Institute in New York.

ADDRESSES AND ORIGINAL ARTICLES

ON VACCINE THERAPY AND IMMUNISATION IN VITRO.

By Sir Almroth Wright, K.B.E.; C.B., M.D., D.Sc. Dub., F.R.S.,

PRINCIPAL OF THE INSTITUTE OF PATHOLOGY AND RESEARCH, ST. MARY'S HOSPITAL; PROFESSOR OF EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON.

(Concluded from p. 284.)

Specific and Non-specific Immunity.

It has already been indicated above that the terms "specific" and "non-specific" are terms of ambiguous signification. Let me justify this.

When we speak of "specific" immunising response, we may mean that infection or its equivalent—i.e., the inoculation of a vaccine—renders the blood bactericidal to the homologous microbes, and only to these; and when we attach this meaning to "specific immunising response" we should, of course, mean by "non-specific immunising response" the acquirement of bactericidal properties for heterologous, as well as homologous microbes.

We may, however, when we use the terms "specific" and "non-specific" be thinking not of the question as to whether immunising response gives protection against one or more varieties of microbes, but of the question as to whether the antibacterial substances brought into play operate "specifically"—each affecting only one species of microbe, or whether they operate "non-specifically"—each affecting more than one species.

Having realised that the terms "specific" and "non-specific" are terms which carry these two distinct meanings, it will avoid confusion if we call the thesis that infection and vaccination immunise only against homologous microbes: "*the doctrine of purely homologous immunising response,*" and the antithetic thesis that protection is acquired also against heterologous microbes: "*the doctrine of conjointly homologous and heterologous immunising response.*" Similarly, we should do well to call the thesis that there are special antibacterial substances for each kind of microbe: "*the doctrine of specific antibodies*"; and the antithetic thesis that there are antibacterial substances which operate upon more than one kind of microbe: "*the doctrine of non-specific antibodies.*"

IS THE IMMUNISING RESPONSE SPECIFIC?

Having clarified the issues we may now make inquiry from the facts, first, as to whether immunising response is specific or non-specific, and secondly, as to whether the antibodies which are native to the blood or are engendered there by infection and vaccination, are specific or non-specific. The answer to the former question is given in many of the protocols of immunisation in vitro already adduced or to be adduced later, as well as in numerous others published and unpublished. A study of the protocols referred to shows that Tuberculin B.E. gives immunising response upon staphylococcus; that staphylococcus vaccine gives immunising response upon streptococcus, and typhoid vaccine operates in the same way upon staphylococcus. Further, it would seem—at any rate in the case of my own blood—that better immunising response is obtained upon staphylococcus with Tuberculin B.E. than with staphylococcus vaccine. I shall presently have something to say with respect to this last finding.

When we pass from immunising operations in vitro to immunising operations in vivo we again find clear evidence of "non-specific"—i.e., heterologous response. Fig. 4 gives a very convincing example of response obtained upon staphylococcus by an intravenous inoculation of a coliform vaccine. We have here first a negative phase of diminished, and then a positive phase of increased hæmo-bactericidal action exerted upon the staphylococcus.

And let me, in this connexion, call attention to two points. The first is a question of terminology. It relates to the fact that severe and rapidly supervening constitutional symptoms, such as follow intravenous inoculation, and followed it here, are in the current jargon of medicine, designated "protein shock." This terminology is to be deprecated because there attach to this term quite erroneous implications. (1) The term suggests that in the case where vaccines produce protein shock this is produced by active agents other than those which produce ordinary immunising response. (2) The term further suggests—for it is employed only in connexion with intravenous injections—that protein shock is produced only by intravenous inoculations. Those who have administered large doses of typhoid vaccine hypodermically, and have witnessed the resulting supervention of shock in patients, and in particular in patients who have immediately after inoculation engaged in active exercise, will not require to be told that shock can follow when a severely toxic dose of a vaccine given by the subcutaneous channel has been carried into the circulating blood. Another vice of the term "protein shock" lies in its assimilating intravenous inoculations of vaccine to intravenous inoculations of milk, foreign serum, and such like, in lieu of assimilating these injections of foreign albuminous substances to inoculations of vaccine. And an even more serious vice is that the term "protein shock" carries with it the suggestion that non-specific immunising response is a product peculiar to intravenous injections of foreign proteins when it is, in point of fact, a general property of vaccines.

A final point to which I want to draw attention relates to the leucocytic counts inserted at the foot of *Fig.* 4. These figures illustrate the point that inoculations of vaccine, and in particular, severe inoculations, such as that here in question, are followed by a phase of leucopenia, followed by a phase of leucocytosis; and the figures are inserted here to bring out the point that the increased bactericidal effect shown in the fourth compartment of the slide cell is achieved quite independently of any leucocytosis.

Immunising response in vivo is, I need now hardly say, not confined to the case of coliform vaccines. We have evidence that streptococcus gives immunising response in vivo upon staphylococcus, and similarly, staphylococcus vaccine upon streptococcus. And these are results obtained by measurements of phagocytic and of sero-bactericidal response—in other words, measurements which cannot be falsified by variations in the number of circulating leucocytes. Let me defer for a moment what I have to say about the importance of these findings for vaccine therapy.

For there can be set off against the protocols of experiments showing non-specific immunising response others which favour the idea that immunising response is specific. I am thinking here of the experiments set out in Charts 32 and 44[15] reproduced in my "Studies on Immunisation" (pp. 418 and 425), and I have in view also some unpublished experiments, and among these a peculiarly striking one made by Dr. John Freeman. In the experiments in question (they were, in each case, massage experiments) the patients' bloods were tested to two microbes (in Dr. Freeman's case the blood was tested to five), and immunising response was obtained in each case only to that microbe which was from the clinical and bacteriological evidence adjudged to be causally associated with the patient's malady. But obviously, we have no reason to suppose that every species of microbe can immunise against every other species.

ARE THE ANTIBODIES SPECIFIC ?

The study of the question as to whether the antibodies which are native to the blood and also those engendered by inoculation operate upon one kind of microbe to the exclusion of all others has, for the immunisator, only a subordinate interest. A few points may, however, here be referred to. W. Bulloch and G. T. Western,[16] dealing with antibodies native to the blood, found that the opsonins which operate upon the tubercle bacillus can be removed from the serum without removing the opsonins for staphylococcus and vice versa. They found, further, that the opsonin for staphylococcus can be removed without removing the opsonin for the *Bacillus pyocyaneus*. On the other hand, it has been shown (the data will be found in my "Studies on Immunisation," pp. 50 and 51) that treatment of the serum with dead cultures of typhoid and cholera extracts the bactericidins for both species of microbe.

Let me now supplement the points already brought forward by one more. The work of Shattock and Dudgeon—it was, it will be remembered, carried out with melanin particles—suggested that "phagocytic avidity" was non-specific. This conclusion is confirmed by the observations of my sometime fellow-worker, Dr. R. Hare, dealing with the bloods of cases of puerperal septicæmia. These observations show that increased and diminished phagocytic avidity to streptococcus goes hand in hand with increased and diminished phagocytic avidity to staphylococcus.

GENERAL CONCLUSIONS.

I should now like to set out the conclusions which seem to me to follow from the data which we have been considering.

Doubtless it seemed paradoxical, and, therefore, doubtful and unacceptable, when I said that when I operate upon my blood with a tubercle vaccine (B.E.) I get better—that is, more emphatic, and for the same dose employed more consistent—immunising response than when I operate with staphylococcus vaccine. In connexion with it I am not going to be rash enough to suggest that the reader should abate anything of his faith in its being a general law of nature for the best immunising response to be obtained by the use of a homologous vaccine. I do not want to do anything more than suggest that a rule such as this might quite well be open to exception. It might be open to a general exception if the heterologous vaccine in question were, as compared with the homologous vaccine, more easily soluble in the blood fluids. And it might be open to an individual exception if a particular patient's blood exerted less lytic action upon a vaccine made with his own microbe than it did upon a vaccine made from a microbe other than the infecting microbe.

Anyone who goes as far as to accept the possibility of such exceptions to rule will be prepared to let the superiority of a vaccine A over a vaccine B—even if the vaccine A should be heterologous and the vaccine B homologous—be decided by laboratory experiment and, moreover, will be prepared to look upon such experiments without parti pris. But while I would plead that the question of superiority of one kind of vaccine over another is one that can be settled only by experiment, none the less I want to put two general points. They are the following:—

In cases where the nature of the infecting agent cannot be determined, advantage very often accrues from inoculation with vaccines made from microbes which are, in all probability, different from those with which the patient is infected. When I say this I have in view (well knowing that these and all other bacteriologically undiagnosed affections are of debatable ætiology) articular rheumatism and phlyctenules of the cornea. It would, I think, sheer obstinacy to let doubt respecting the ætiology of these affections and a passionate conviction that immunising response is purely specific, hold us back from inoculating in the one case vaccines made from intestinal streptococci, and in the other case minimal doses of Tuberculin B.E. Essentially the same reasoning would, I think, apply in dealing with infections such as glanders, in which homologous vaccines have been tried time and again without success. One might, I think, surmise that such a microbe as that of glanders furnished a very ineffective antigen, and one might, by consequence, reasonably try whether anything useful could be done with a non-homologous vaccine.

Principles of Dosage.

I turn now—and this will complete what I propose to say here on the subject of vaccine therapy—to the question as to whether we can, with the knowledge gained by the study of immunisation in vitro, add anything to the principles of dosage which were learned when we had only the clinical symptoms and measurements of the opsonic index to guide us. It will be remembered that the most important of the general principles of dosage arrived at by watching and measuring the opsonic index of patients was that the doses of vaccine employed should be inversely as the amount of infection. Further, that, with a view to avoiding negative phases, the doses given to heavily infected patients should be much smaller than those given to the lightly infected, and should represent a very small fraction of the doses administered in prophylactic operations undertaken upon the healthy. This principle finds interesting confirmation when we carry out experiments in vitro. We take a series of equal measured blood volumes and implant into these graduated quanta of living microbes, and then add to each implanted volume one and the same dose of vaccine. It does not require a great effort of imaginative vision to discern that we have here analogous conditions to those which prevail in lightly and heavily infected patients. Instructive illustration of the effects produced is furnished in the subjoined protocols.

Expt.—Capillary tubes were prepared with a stem about a foot and a half in length and of almost uniform bore, and a 10 c.mm. division mark was then placed on the distal end of the stem. Blood was then obtained from my finger, and then there was aspirated into one of the capillary tubes as a forerunner 10 c.mm. of a 1000-fold dilution of a broth culture of staphylococcus; and then, as after runners, ten 10 c.mm. volumes of blood. The same procedure was carried out with two other portions of blood, the one inoculated with a smaller and the other with a larger dose of Tuberculin B.E. After 24 hours' incubation the blood-clots were blown out in order, each series arranged in a row upon a separate strip of filter paper. The clots were then, as soon as they had by absorption of fluid become adherent to the filter paper strips, treated with 1 per cent. saponin, and the strips were then introduced into a beaker full of water, being applied to its interior wall after the fashion of a cornice. When hæmolysis was complete the filter paper strips were placed in a Petri dish containing water, and the decolorised clots were then aspirated into a capillary tube and transferred in proper order to a microscopic slide. They were then dried and stained. The number of colonies which developed in each of the three series of clots is set out in Table XX.

---

[15] These charts should, however, be studied in conjunction with Charts 7 and 8, pp. 387 and 388, loc. cit.

[16] Proc. Roy. Soc. B, 1906, lxxvii.; reprinted in my Studies on Immunisation, pp. 180–185.

TABLE XX.

—	No. of colonies of staphylococcus in volumes.										No. of colonies in—		
	1	2	3	4	5	6	7	8	9	10	The whole 10 vols.	Vols. 1–5	Vols. 6–10

Blood inoculated with B.E. 1 in 500 million ..	4	10	9	15	3	1	0	0	0	0	42	41	1

Note.—The small number of colonies in Vols. No. 1 is no doubt due to this volume of blood being very highly diluted by the forerunner volume of tuberculin in salt solution.

When we glance, to begin with, at the rubric in which are set down the aggregate number of staphylococcic colonies which developed in the three capillary tubes, we see that the aggregate is, in the case of the blood containing 1 part of B.E. in 1000 million, less by nearly 50 per cent. than it is in the control blood, and that the aggregate number of colonies which developed in the blood which contained 1 part of B.E. in 500 million is nearly double that in the control. If demonstration were necessary of the impossibility of judging a dose of vaccine by the epitomal result produced upon a series of different bloods of patients, such demonstration is furnished here. For, judged by the epitomal effect produced in the whole series of volumes, a dose of 1 part in 500 millions of tuberculin is a large overdose for my blood. Very different are the conclusions which emerge when we analyse the results and consider separately that which applies to the first five and that which applies to the last five volumes of the series. We then see that in the case of the heavily implanted blood volumes the effect of the larger dose of vaccine is to give us in these volumes more than twice as many colonies as in the control blood, and nearly four times as many as in the less heavily vaccinated blood. But when we turn to the effect produced upon the more lightly implanted bloods we see that the larger dose of vaccine enhances the bactericidal power more than does the smaller dose.

An essential similar experiment is Table XXI.

Expt. 8.4.31.—Same technique. Forerunner 15 c.mm. volumes of $\frac{\text{staph.}}{1000}$; afterrunners, ten 15 c.mm. volumes of A. E. W.'S blood.

Increased Phagocytosis Obtained by Inoculation of Blood in vitro.

Precisely similar effects—and effects which show that we are here dealing with a general law—are seen in phagocytic experiments in which an inoculated blood is tested with progressive dilutions of a staphylococcus culture.

Phagocytic Expt.—A. E. W.'s blood centrifugalised with different strengths of Tuberculin B.E. and different strengths of staphylococcus vaccine. (Table XXII.)

TABLE XXII.

—	Phagocytic indices tested with—

Duration of centrifugalisation ..	½ min.	1 min.	2 min.	2 min.

The rationale of these results is obvious. They show us that when the blood is implanted with a moderate quantum of living microbes and a moderate quantum of vaccine is added, the antigens derived from these twin sources may constitute, taken together, an optimum immunising stimulus. They show us further that when the implant of living microbes is cut down, and the antigen derived from this source is correspondingly diminished, the quantum of vaccine may be profitably increased. And vice versa when the implant of living microbes is increased the quantum of vaccine must be correspondingly cut down.

Before leaving this question a word may be said concerning the situation in which we find ourselves when dealing with a patient who has an acute infection, and we are in doubt as to whether he can still make response to a vaccine, and if so as to what quantum can be safely administered. In this situation we can, by recourse to what I have called the Vaccine Response Test[17] obtain the required information.

The "*Vaccine Response Test*" consists in adding to the patient's blood in vitro graduated quanta of the vaccine which it is proposed to use, and seeing whether any of the doses employed enhance, after some arbitrarily fixed period of incubation, the phagocytic power of the patient's blood, or whether all doses of vaccine impair that power.

I have elsewhere[18] published data showing the help that can be obtained from the vaccine response test. But I should like to say here that when in a rapidly advancing infection we needs must decide in the dark, it is always advisable to try the effect of inoculating with a very small dose of vaccine. For the advantage that may accrue if the patient's blood is still capable of making immunising response far outweighs the harm that might result if his were incapable of making immunising response, and the case already hopeless.

Let me now come back from this digression and consider yet another question in connexion with the dosage of vaccines. I can best introduce the point by recalling that while in the case of ordinary vaccines some of the antigen is in solution, the bulk of it is present in the form of particulate matter which is (I am thinking here in particular of vaccines made from serophytic microbes) not very readily soluble in the blood fluids. It follows that if there is, when the vaccine comes into operation upon the blood, any immediate immunising response, this will be response to that fraction of the total antigen which is in solution in the vaccine, or is, as the case may be, immediately brought into solution by the blood fluids. Such subitaneous response takes in the typical curve of opsonic response (figured in my "Studies of Immunisation," p. 379, Chart I), the form which I there called a "false rise," and this

[17] THE LANCET, 1923, i., 473.

[18] Ibid., p. 475, 1923.

"false rise" is, according as the quantum of antigen afterwards dissolved is appropriate or excessive, followed by either a positive phase unpreceded by a negative, or a negative phase followed by a positive. All this is very clearly shown in the subjoined series of protocols.

There remains one last point which I should like to call attention to. It is again a point of similarity between the effects produced by infection in vivo and those produced by inoculation in vitro. It will perhaps be remembered that I have from the very outset called attention to the fact that patients suffering from lupus and generally from strictly localised forms of tuberculosis,[19] unaccompanied by constitutional disturbance, have a very low opsonic index to tubercle.

The phenomenon is clearly not one of the same order as the negative phase. For negative phases supervene, not upon minimal auto-inoculations, such as can here come in question, but only upon large inoculations or auto-inoculations. Further, a negative phase is practically always followed by the response in the form of a positive phase, and the indices of these patients remain, as can be inferred from the fact that their tuberculo-opsonic indices are uniformly low, chronically below standard. Every one of these points finds its parallel in the results obtained by the inoculation of the blood with minimal quanta of vaccine.

It has already been seen in one of the protocols of hæmobactericidal experiments which I have shown—and I could have very easily produced others showing the same—that when minimal quanta of living microbes are implanted into the blood on the one hand and serum on the other, more microbes develop into colonies in the blood than in the serum. The same thing may be seen when the sera of bloods which have been treated with minimal quanta of vaccines are tested for bactericidal power by implantation with staphylococcus. Such sera are very often found to furnish a better culture medium for staphylococcus than the control sera. And again, the addition of minimal quanta of vaccine to a phagocytic mixture often lowers the phagocytic index.

In conclusion, I have to express my gratitude to my fellow-workers, and in particular Prof. A. Fleming, Dr. Leonard Colebrook, Dr. R. M. Fry, and Dr. R. Mummery, for having very generously placed not only their work, but also their ideas at my disposal.

---

[19] The data relating to this question and also important confirmation of these data by Prof. W. Bulloch are to be found in my Studies of Immunisation. (pp. 118, 152, and 146–148).

PROPOSED COMPLETION OF KING'S COLLEGE HOSPITAL.—The authorities of this hospital, in view of the powers conferred by the Local Government Act of 1929 upon county councils, have invited the London County Council to discuss with them the purposes to which the completion of the building might be devoted. In view of the desirability of providing maternity beds, it is suggested that further accommodation of this kind might be supplied in association with the council, whose survey of the hospital needs of its area showed that at least another 1000 beds were needed in South London, many of them maternity beds.

GORHAMBURY AS A TEMPORARY MENTAL HOSPITAL.—The Earl of Verulam's seat, Gorhambury, St. Albans, has been taken on lease by the Middlesex county council as a temporary mental hospital. The lease, which includes 18 acres of surrounding land, is to run for from five to seven years pending the completion of the new hospital at Porter's Park. The council will spend a maximum of £10,000 in adapting and equipping the house to accommodate 150 patients. The first section of the Porter's Park scheme (1000 patients) will cost £520,336.

THE PULMONARY ARTERY IMPRESSION ON THE ŒSOPHAGUS.

BY JOHN PARKINSON, M.D., F.R.C.P. LOND.,
PHYSICIAN (WITH CHARGE OF OUT-PATIENTS) AND PHYSICIAN IN CHARGE OF THE CARDIAC DEPARTMENT, LONDON HOSPITAL; PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART;

AND

D. EVAN BEDFORD, M.D., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE MIDDLESEX HOSPITAL.

(WITH ILLUSTRATIVE PLATE.)

WHEN a thick suspension of barium sulphate is swallowed, an observer may see by radioscopy the whole course of the œsophagus, which is, in a special sense, visualised. The procedure is so simple, and the anatomical relations are so favourable, that for years cases of dysphagia have been investigated in this way. It is an obvious method to employ in disease of the œsophagus itself (cardiospasm, simple stricture, and carcinoma), and in conditions which may produce pressure upon it (aneurysm and intrathoracic neoplasm). Though its use in patients with thoracic aneurysm is subsidiary to inspection and radiography of the aorta and the sac itself, yet barium in the œsophagus often helps to define the swelling and to localise it.

Radiology was first applied to the diagnosis of cardiac disease long before the war, but till recently it has been little used in this country as part of the systematic examination. Yet it could be maintained that it gives as much useful information—taking a large consecutive series of patients—as electrocardiography.

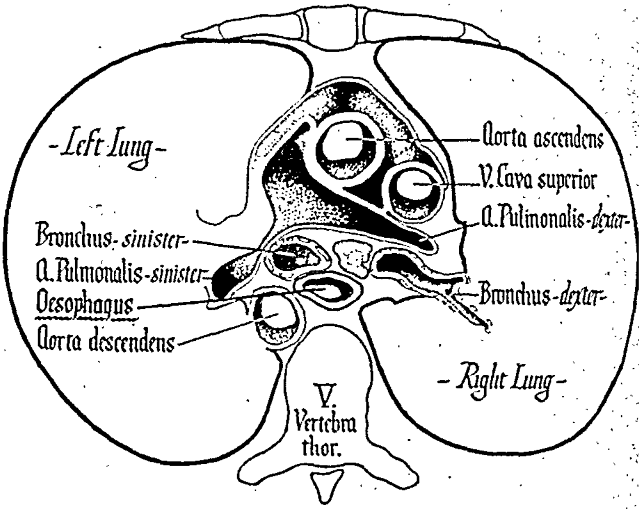
Apart from the matter of aneurysm, the relation of the œsophagus to the aorta has been used as a means of measuring the diameter of the aorta in normal and pathological states. As the arch of the aorta passes backwards and to the left to reach the spine, its wall touches the œsophagus. The relation is so close that on the barium-filled œsophagus appears an impression which is called by Kreuzfuchs[4] the aortic bed. He made use of the fact in measuring from the middle of this impression or bed transversely across to the most lateral point of the aortic knuckle to obtain the diameter of the aortic arch (Fig. IV.). This natural impression by the aorta on the œsophagus is also visible in the first oblique position—i.e., with the patient turned *half-left*. The opaque bolus is momentarily held up at this level, for there is not only displacement, but constriction (Fig. XII.).

The second current application of the visualised œsophagus to cardiac diagnosis is the displacement produced by the enlarged left auricle in mitral stenosis. The worth of this almost pathognomonic sign of mitral stenosis has not even yet been realised. It is seen better in the first oblique position (patient facing half-left) than in the anterior (Fig. X.).

Still other conditions have been studied by observing their effect upon the œsophagus. There is a congenital anomaly of the aorta in which the aortic arch passes over the right bronchus instead of the left (right-sided aortic arch); here the œsophagus presents a convexity to the left. In this condition there may be a diverticulum of the aorta behind the œsophagus (persistent left aortic root), giving rise to the left subclavian and ductus arteriosus; or the aorta after passing over the right bronchus may cross to the right behind the œsophagus, displacing it forwards and to the left. When the left subclavian takes an aberrant course behind the œsophagus, dysphagia may result (dysphagia lusoria), and there may be a diagnostic dent on the barium-filled œsophagus. A similar dysphagia may be produced when the aortic arch is normally situated on the left, by an aberrant right subclavian artery running behind the œsophagus.

In making routine examinations by radioscopy in the first oblique position, we have noticed another impression on the œsophagus, one which seems to have escaped attention. It lies between the two impressions already mentioned, the aortic above and the auricular below, forming a sort of "middle arc" in the first oblique view of the heart. In some degree it is often seen in healthy persons, but it is modified or exaggerated in certain diseases, particularly, we think, in those associated with enlargement of the pulmonary artery and its branches.

FIG. I.



Transverse section of the normal thorax at the level of the fifth thorac vertebra (specially drawn after Eycleshymer and Shoemaker, 1911 The relation of the pulmonary artery and its right branch to the le bronchus and to the œsophagus is shown.

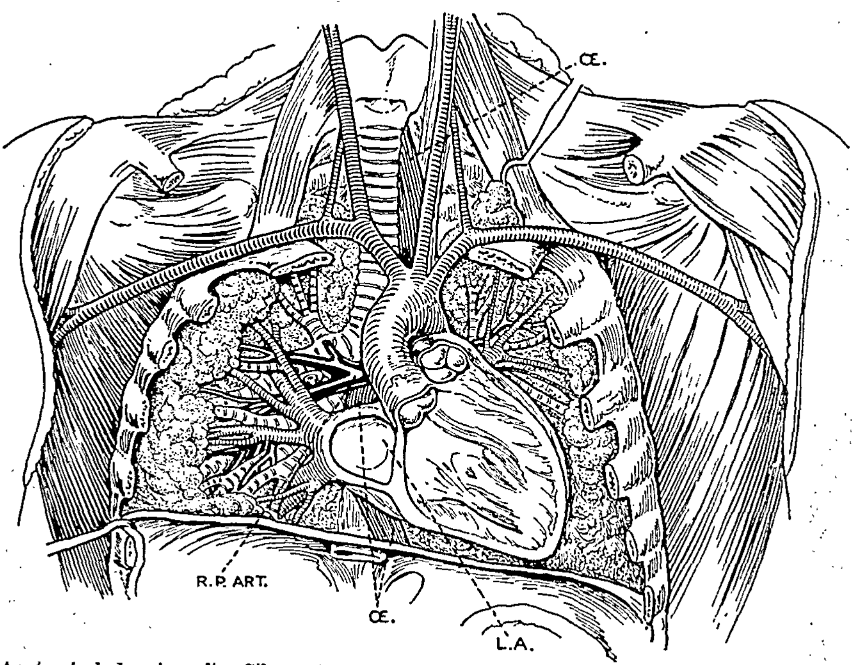
Course and Calibre of the Œsophagus in the Thorax.

Viewed from the front, the œsophagus does not run vertically downwards, but inclines to the left of the middle line from the neck to the fourth thoracic vertebra, there to regain the middle line or even to bear to the right of it where the aortic arch is passing on its left. Below this it often takes another gentle curve to the left, which becomes accentuated in the lower portion, where it crosses in front of the descending aorta. In old people with atheroma of th descending aorta, the lower curve of the œsophagu to the left may be pronounced. During inspiration a in a long chest the œsophagus tends to be straighte than during expiration *or in a short chest*, or where th diaphragm is high.[2]

Viewed from the side, the œsophagus as a whol shows a long, slight curve backwards behind th aortic arch and the heart. It is applied to them muc more intimately than to the spine or to the descendin aorta, which so closely follows the spine. In fact from the fifth thoraci vertebra the œsophagu leaves the spine and lie closely on the back o the heart. In kyphosis, for instance, it does not adhere to the bent spine but to the heart, thus taking a more direct course. It is noteworthy that the œsophagus is only firmly fixed at the pharynx and the diaphragm; nowhere else in its course are there firm attachments, so that it is easily displaced by adjacent swellings.

Much has been written on the natural constrictions of the œsophagus, chiefly from the anatomatical and surgical aspects. Admitting the relative narrowing at its origin, at its passage through the diaphragm, and at its termination in the stomach, we think that constrictions described in its intrathoracic course may be of a different nature. Two are described—one where the aortic arch abuts on it; the other where the left bronchus crosses

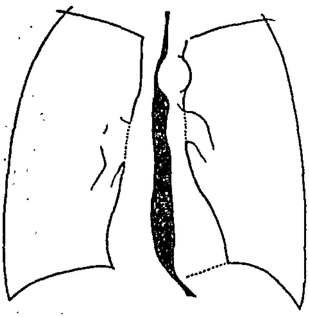
FIG. II.



Anatomical drawing after Sibson (Medical Anatomy, London, 1869, Plate VI.). Anterior view after removal of the right auricle and right ventricle. The course of the œsophagus (Œ.) is shown in relation to the arch of the aorta, the bifurcation of the trachea, the right pulmonary artery (R.P. Art.), and the left auricle.

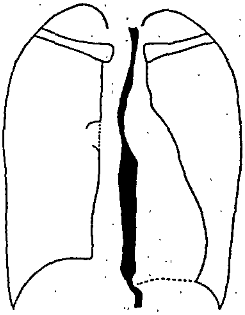
it obliquely. From the radiological aspect these are natural *compression* stenoses, for there is narrowing as well as deviation. There is not only an aortic bed, but also a left bronchial bed.[5] These are grooves on the œsophagus which determine at once the cause and site of the constrictions.

FIG. IV.



Outline of teleradiogram (anterior view) from a healthy man, aged 61, to show the aortic bed on the barium-filled œsophagus, and also the slighter pulmonary artery impression at the level of the dividing pulmonary artery—i.e., of the hilar branches.

FIG. V.

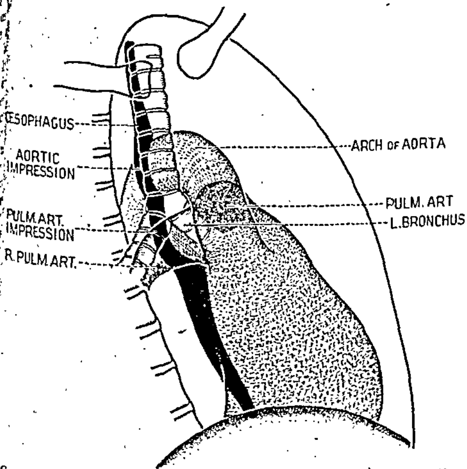


Outline of teleradiogram (anterior view) from a woman, aged 30, with congenital heart disease. It shows a slight impression on the œsophagus from the small aorta and below it a larger impression due to the larger pulmonary artery.

Relations of the Œsophagus to the Heart and Great Vessels.

The arch of the aorta passes backwards, then downwards and to the left or reach the spine at the fourth thoracic vertebræ, whereafter it continues as the descending aorta. The arch crosses in front of and then passes backwards on the left of the œsophagus, which it touches. The œsophagus lies behind and a little to the left of the trachea. Opposite the fourth vertebra the aorta pushes it to the middle line. At the tracheal bifurcation, facing the fifth vertebra, the œsophagus has again returned to the left, so that it is more in contact with the left bronchus than the right. In the angle of the bifurcation is a group of glands, but immediately below this the right pulmonary artery, running transversely within the pericardium, is in direct anterior relation to the œsophagus (Figs. I. and II.). We have confirmed this relation in the cadaver. If a sound is placed in the œsophagus, a finger passed through the cut pulmonary artery into its right branch comes into close contact with the sound. In the cross-section it will be seen that the main trunk of the pulmonary artery arches and divides at this level in close proximity to the œsophagus, though less directly in anterior relation. Thus below the aortic arch there is a segment of the œsophagus in contact with the left bronchus and the right pulmonary artery, and under the influence of the adjacent pulmonary stem (Fig. III.). Below this middle segment—which is under our consideration—the œsophagus lies behind the left auricle, round which it curves before piercing the diaphragm.

FIG. III.



Composite teleradiogram, semi-diagrammatic, showing the normal relations in the first oblique position (patient *half-turned left*). As the aortic arch passes backwards, it grooves the œsophagus, producing the upper or aortic impression. Below this is the "pulmonary artery impression," or middle curve, due to the pressure of the left bronchus, the right pulmonary artery, and the main pulmonary stem upon the œsophagus at this level. The lower or left auricular curve on the œsophagus is slight.

Posteriorly, the œsophagus lies loosely on the vertebral column, until it comes forward from about the fifth vertebra to cross the descending aorta so as to lie in front and on its left in their separate passage through the diaphragm.

The Pulmonary Artery Impression in Health.

There is an uncharted portion of the normal œsophagus, as seen by radioscopy and in radiograms after the ingestion of barium, between the aortic impression above and the left auricular impression below. This segment, as already described, is related to the left bronchus and right pulmonary artery, and adjacent to the pulmonary arch itself. We have investigated it radiologically—chiefly in the first oblique position—by inspection after giving the subject several spoonfuls of a thick paste of barium sulphate—e.g., citobaryum with a little water—and then by teleradiograms (6 ft.) taken directly after inspection.

This middle segment is about 2–4 cm. in length, and is best identified by its nearness to the lucent triangle, due to the left bronchus, which separates it from the dense shadow of the dividing pulmonary artery in front. It varies in prominence according to the degree of rotation of the subject. The optimum position is found empirically, usually at about 45°. Often quite straight, it as often occurs as a slight curve backwards, or at least as an impression on the anterior border. Then we see the barium-filled œsophagus built of three backward curves; from above downwards: (1) the aortic impression, (2) the "pulmonary artery" impression, and (3) the left auricular impression (Fig. VI.). Sometimes (1) and (2) are combined forming a single vascular curve above the left auricular curve (Fig. X.). Where this obtains, and there are two curves in all, it is usually evident that the upper curve is larger and extends lower than could be accounted for by the aorta alone. If necessary, this can be proved by comparison with the anterior or the second oblique position. It is surprising in normal individuals how slight, almost non-existent, may be the lowest curve—i.e., that adjacent to the normal left auricle. This renders all the more noticeable the middle curve, or the combined upper and middle curve.

Even on the anterior view a slight modification of the course of the œsophagus is occasionally discerned below the aortic bed (Fig. IV.), and measurements show that it corresponds in position with the middle curve described on the lateral view. Kreuzfuchs[5] ascribes the inclination below the aortic bed simply to the return of the œsophagus to its vertical course, and, incidentally, refers to the slight effect of the left bronchus upon its lumen.

In the second oblique position (patient facing half-right) a slight aortic impression is generally visible after barium, and below it is occasionally seen a slight impression again corresponding in position with the curve we describe (Fig. VII.).

The Pulmonary Artery Impression in Disease.

Although the "pulmonary artery" curve is often seen in conditions where there is no clinical reason for thinking that the pulmonary artery is abnormal, we find it more pronounced in conditions where the symptoms or the nature of the disease lead one to expect dilatation or engorgement of the pulmonary artery and its branches. This exaggerated pulmonary impression on the œsophagus is produced partly by direct imprint of the swollen right pulmonary artery, and partly by the left bronchus pressed against the œsophagus by the distended pulmonary stem.

An enlargement of the pulmonary arc will often have been noticed at the anterior view. By rotation of the patient to his left, on giving barium it is quickly seen that the middle curve on the œsophagus corresponds in level to the arc of the enlarged pulmonary artery. In particular, this middle curve of the œsophagus begins at the level of the summit of the pulmonary arch, much as the upper (aortic) curve of the œsophagus begins at the level of the summit of the aortic arch (Figs. VI. and XII.).

Where the aorta is lengthened from atheroma and rises in the chest high above the pulmonary arch, the latter is well seen as a dense shadow in apposition to a long, if shallow, middle curve on the œsophagus (Fig. VIII.). In a case of right-sided aortic arch, in which the œsophagus was displaced, Renander[6] found that the pulmonary artery made an impression on it.

As in the normal subject, the pulmonary artery or middle curve may be separate (Fig. XII.) or it may be combined with the aortic or upper curve (Fig. X.). The combined curve has often been taken as the aortic impression only, its undue length or curvature not being noticed. It is easily identified by placing the finger on the screen opposite the part of the curve in question, and turning the patient from the first oblique into the anterior position. It will then be found that the upper portion of the combined curve corresponds in level to the aortic knuckle, and the lower portion to the pulmonary artery at the lung roots. Where the aortic and pulmonary curves are separate they may, of course, be identified by the same plan. Occasionally, the pulmonary curve fuses with the auricular curve, producing a combined middle and lower curve.

Among the several conditions in which the pulmonary artery may be enlarged can be mentioned congenital heart disease, mitral stenosis, emphysema, goitre, and aneurysm of the pulmonary artery.

In many congenital malformations of the heart the pulmonary artery is enlarged, though by no means in all. It is, perhaps, commonest in association with patent ductus arteriosus. In general the size of the pulmonary artery varies inversely with that of the aorta; certainly when it is large the aorta is usually small. This fact is supported by our findings with the barium method, and in Fig. IX. the middle or pulmonary curve is seen to be longer and more noticeable than the upper or aortic curve. At the same time the lower or auricular curve is slight, for the left auricle is not affected (cf. mitral stenosis, e.g. Fig. X.). Not only in the first oblique position, but also in the anterior, the pulmonary artery impression may be pronounced in congenital disease (Fig. V.).

In mitral stenosis the enlarged pulmonary artery is seen in the anterior position as a prominence of the middle arc on the left heart border. It may also be seen in the first oblique position accentuating the middle curve of the œsophagus. The small aorta of this lesion forms but a slight impression on the œsophagus. In comparison, the middle curve is large, or more often it blends with the higher and slighter aortic impression to make a long and convex combined curve (Fig. X.). Yet many patients with mitral stenosis do not show the middle curve well, possibly because the large left auricle rises too high in the mediastinum to give it room.

In published accounts of the radiology of mitral stenosis the pulmonary artery impression has sometimes been reproduced on the accompanying figures without comment in the legend or text—e.g., Steel,[8] his Fig. 7; and Rigler,[7] his Fig. 8 (see also his Fig. 6).

Emphysema and other chronic pulmonary diseases sometimes lead to enlargement of the pulmonary artery demonstrable on X ray examination. In Fig. XII. this makes its mark on the œsophagus as a middle curve. In a proportion of cases of goitre, where this is affecting the heart, the pulmonary artery becomes not only more pulsatile, but more prominent, and we have examples of its imprint on the œsophagus. Aneurysm of the pulmonary artery is rare, and mostly seen with congenital defects (Fig. XI.).

Apart from cardiac conditions, it is interesting to note that in many of the published radiograms showing great dilatation of the œsophagus from cardiospasm, the lax and distended œsophagus happens to facilitate and thereby to emphasise the curve we describe (e.g., Walton,[9] his Figs. 447 and 453). As the region of the left bronchus is a favourite site for carcinoma of the œsophagus, this will be remembered and excluded before this particular displacement is referred to a cardiac condition (e.g., Assmann,[1] his Fig. 397, p. 485). Cancerous glands in the bifurcation of the trachea may also simulate the pulmonary artery curve, and such a case is figured by Grashey,[3] his Fig. 8A, p. 49.

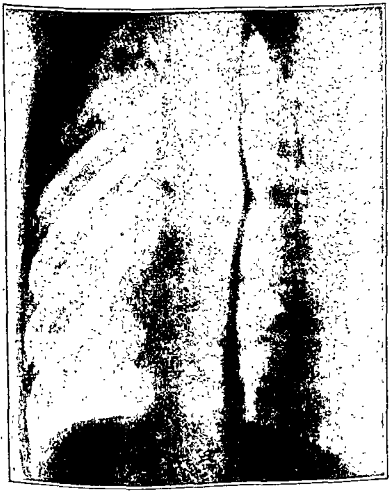
DRS. [illegible]IN PARKINSON
AND
D. E[illegible]N BEDFORD:

THE [illegible]ULMONARY ARTE[illegible] IMPRESSION ON T[illegible] ŒSOPHAGUS.

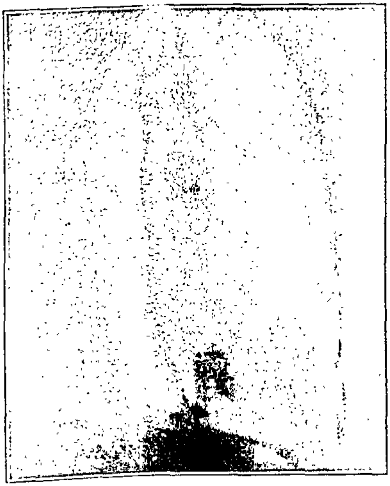
Teleradiogram (first [illegible] position) of normal heart. Man aged 50. The [illegible] œsophagus shows from above downwards: (1) [illegible]rtic curve; (2) the pulmonary artery curve [illegible] an[illegible] slight left auricular curve.

FIG. VII.



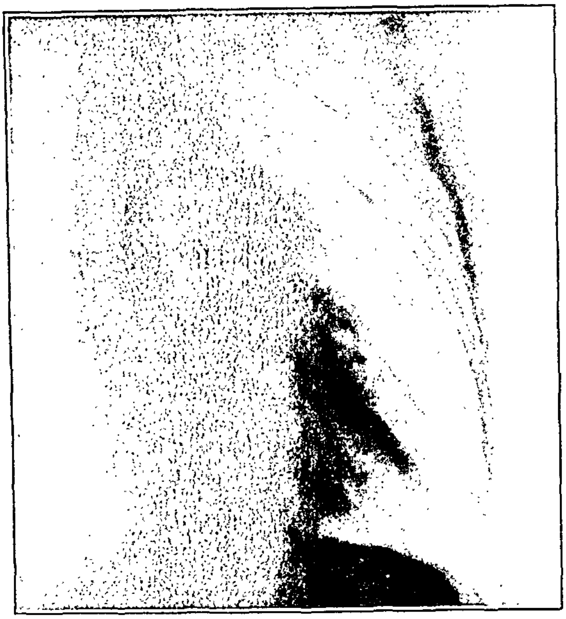
Teleradiogram (second oblique position) of normal heart. Man aged 60. Below the aortic arch is seen the bifurcation of the trachea, and alongside it the pulmonary artery and its left branch. The œsophagus shows a slight aortic curve with convexity forwards, and below it a pulmonary artery curve with convexity backwards—i.e., to the right.

FIG. VIII.



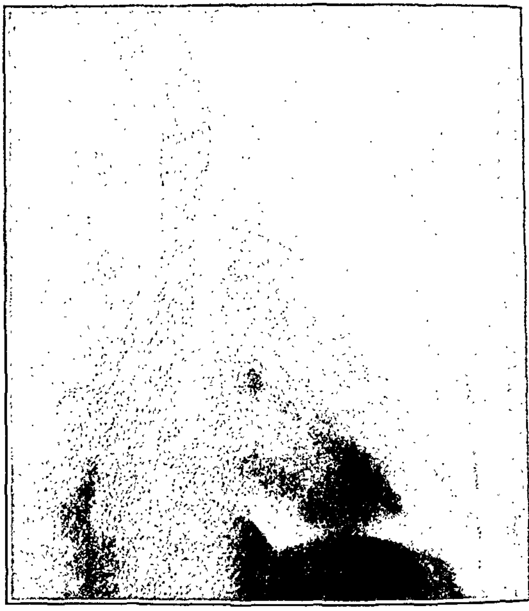
Teleradiogram (first oblique position) of atheroma of aorta. Man aged 69. Below the high aortic curve of the œsophagus is a long, shallow middle curve, adjoining which is the dividing pulmonary artery (denser shadow), separated from the œsophagus by the left bronchus.

Fig. IX.



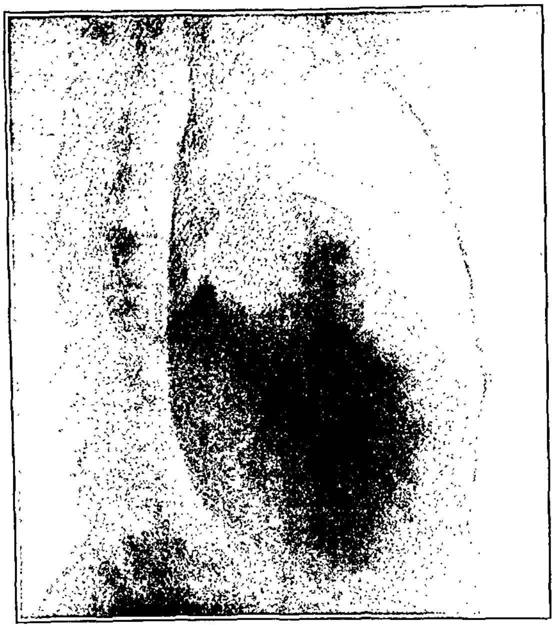
Teleradiogram (first oblique position) of congenital heart disease with enlarged pulmonary artery. Man aged 31. The thin streak of barium in the œsophagus shows a small aortic curve, a large middle curve (behind the large pulmonary artery), and a shallow auricular curve.

Fig. X.



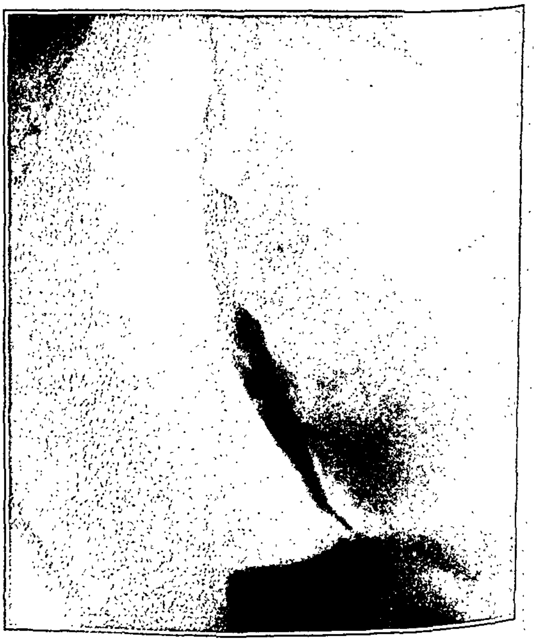
Teleradiogram (first oblique position) of mitral stenosis with fibrillation. Man aged 44. The œsophagus shows two curves only—a combined aortic and pulmonary curve above and a prominent auricular curve below. The left bronchus separates the dense pulmonary artery from the lower half of the combined upper curve.

Fig. XI.



Teleradiogram (first oblique position) of congenital heart disease with aneurysm of the pulmonary artery. Woman aged 48. The œsophagus shows a small aortic impression, a distinct pulmonary artery impression, and the left auricular curve.

Fig. XII.



Teleradiogram (first oblique position) of emphysema and aortic atheroma. Woman aged 66.. The relation of the upper œsophageal curve to the aorta, and of the middle curve to the pulmonary artery, is shown.

ON THE PREVENTION OF MALARIA WITH PLASMOQUINE.

BY S. P. JAMES, M.D. LOND., F.R.S.,
MEDICAL OFFICER AND ADVISER ON TROPICAL DISEASES TO THE MINISTRY OF HEALTH; MEMBER OF THE MALARIA COMMISSION OF THE LEAGUE OF NATIONS;

W. D. NICOL, M.B. LOND., D.P.M.,
DEPUTY MEDICAL SUPERINTENDENT, HORTON MENTAL HOSPITAL, EPSOM;

AND

P. G. SHUTE,
SENIOR ASSISTANT, MALARIA LABORATORY, MINISTRY OF HEALTH.

IN THE LANCET of June 6th (p. 1248) reference was made to our experiments having for their object to ascertain whether any known or reputed anti-malarial remedy is a true preventive of human malarial infection contracted in the natural way by the bites of mosquitoes. The principles and technique of our method of test were described, and our finding was reported that the synthetic preparation, Beprochin (now supplied as tablets labelled "Plasmoquine brand of beprochin"), successfully fulfilled the requirements of the test in all of eight experiments, while similar trials with six other preparations invariably failed to do so. Following this finding, we repeated the experiments with plasmoquine on a further series of patients at the Horton Mental Hospital, Epsom, and two of us tested its prophylactic efficacy on themselves, one (W. D. N.) to protect against benign tertian infection, the other (P. G. S.) against malignant tertian. The same success having attended these trials, we decided that it would be justifiable to call for volunteers to undertake a confirmatory experiment. In this matter we were greatly assisted by Sir Almroth Wright, who kindly permitted the experiment to be conducted under his auspices at the Institute of Pathology and Research, St. Mary's Hospital, and by Dr. Ian Maclean, Prof. A. Fleming, and other workers in the Inoculation Department of the hospital, who made themselves responsible for the attendance and supervision of volunteers and for other important details. Dr. Wilfred Harris kindly arranged that a patient who was to undergo a course of malario-therapy in St. Mary's Hospital should serve as a control case, and we arranged for other control cases at St. Thomas's Hospital, the West End Hospital for Nervous Diseases, and elsewhere. One of us (S. P. J.), who had not hitherto tested the prophylactic action of the drug on himself, took part in the confirmatory experiment, and the other volunteers were: Messrs. E. V. Bevan, L. J. Clapham, Stanley Cooper, A. G. Cross, W. B. Johnston, A. N. McCrea, R. C. MacKeith, and J. Williams and Miss E. Ward. All are students at St. Mary's Hospital Medical School.

The manner in which the experiment was conducted and its result may be described in diary form, as follows:—

Diary of the Experiment.

July 1st: Infection of a batch of 230 *Anopheles maculipennis* for the purposes of the experiment was begun to-day by feeding on a case of benign tertian malarial fever and subsequent incubation at 25° C. The batch is No. 93. The patient's blood contains 880 gametocytes per c.mm. The count of ex-flagellating male gametocytes in moist preparations is 220 per c.mm.

July 11th: Feeding on the infecting case was repeated every alternate day until the 7th. The count of gametocytes and of ex-flagellating male parasites in the patient's blood has remained about the same as on the first day of feeding. Daily dissection of fed mosquitoes has proved that the batch is heavily infected, as many as 80 or more zygotes being found on the stomachs of some insects. To-day most of the zygotes are ripe and on the point of rupture; a few have already ruptured and discharged their sporozoites into the body fluids of the mosquito. The salivary glands of one specimen contain sporozoites.

July 12th: Sporozoites were found to be present in the salivary glands of all mosquitoes dissected to-day. Of the 230 insects with which the batch was commenced, 94 remain alive.

July 13th: The volunteers, ten in number, attended at 4 o'clock. The purpose and procedure of the experiment were explained, and each volunteer took the first prophylactic dose—namely, one tablet of plasmoquine simplex (0·02 g.). The procedure of infecting the patient in St. Mary's Hospital, who would be a control case, was demonstrated. The patient was bitten by several mosquitoes, one of which was then dissected to verify the presence of sporozoites in its salivary glands. The volunteers were informed that their prophylactic dosage would be one tablet (0·02 g.) three times a day (one after breakfast, one after lunch, and the third at bedtime) for six days, and that they would be infected to-morrow after they had taken the first two of the daily prophylactic doses. Each was given an explanatory card, ruled with headings and spaces, for noting the time at which each prophylactic dose was taken and any toxic or other symptoms observed.

July 14th: Volunteers attended in the afternoon for the procedure of being infected. Prof. W. Jameson and Prof. J. Gordon Thomson, of the London School of Hygiene and Tropical Medicine, Lieut.-Colonel J. A. Sinton, V.C., I.M.S., Director of the Malaria Survey of India, and other interested workers, kindly attended as independent observers. Cards were inspected to ascertain that the prophylactic doses had been taken, and then each volunteer was handed a separate glass jar containing five or six infected mosquitoes. Infection was effected by allowing the mosquitoes to bite the forearm through the mosquito-netting, with which the mouths of the jars were covered. The number of bites received was recorded, and from each jar a mosquito containing freshly drawn blood was selected for dissection, to prove infectivity by finding motile sporozoites in the salivary glands. The result of these dissections was positive in every instance. The numbers of infected mosquitoes by which each volunteer was bitten were: E. V. Bevan, 4; L. J. Clapham 4; Stanley Cooper, 5; A. G. Cross, 2; S. P. James, 4; W. B. Johnston, 2; A. N. McCrea, 4; R. C. MacKeith, 4; E. Ward, 3; J. Williams, 3. The third prophylactic dose on this day was taken by each volunteer ten

minutes after being bitten by the infected mosquitoes, instead of at bedtime. A patient at the West End Hospital for Nervous Diseases was selected as a second control case, and was infected by the bites of six mosquitoes.

July 15th: All taking part in the test attended again for verification of the numbers of bites received, and to ascertain that the prophylactic doses were having no ill effect.

July 17th: All attended again to receive an explanation of the manner in which the result of the experiment would be ascertained and recorded. It was pointed out that the average incubation period in benign tertian malaria caused by mosquito-bites is 14 days, but may be as short as 10 days or as long as 20. It was to be expected that the control case at St. Mary's would begin his malarial attack sometime during the week beginning Monday, July 27th (the 14th day after infection), and it was during that week and the next that the result of the prophylactic experiment would be ascertained and recorded. For this purpose each volunteer was particularly requested: (1) To record, on the second card provided, his temperature twice daily from Friday, July 24th, to Wednesday, August 5th, as well as any symptoms indicating a possible onset of malaria; (2) to attend on July 27th and 31st and August 5th for a specimen of blood to be taken and examined; (3) to keep in touch with us by telephone throughout the period of the experiment, and at its termination to return the cards filled in and signed, together with any personal observations which it might be desirable to note.

July 27th: Volunteers attended, as requested. Benign tertian malaria parasites were found in thin blood films of the control case at St. Mary's, but in neither thick nor thin films of the blood of any of the volunteers. Up to the present (by inadvertence on our part) the temperature of the patient at St. Mary's has been taken only twice daily (at 6 A.M. and 6 P.M.). For this reason it has happened that the actual day on which he commenced his malarial attack is not apparent from the chart, but from to-day his temperature will be recorded every four hours. The finding of parasites in a thin film indicates that, in all probability, he has had slight attacks of fever (lasting, perhaps, only a few hours) for one or two days; in any case, we can take the first date on which parasites were found as indicating the incubation period, which would thus be 14 days. In striking contrast is the fact that no volunteer has observed any symptom indicating the possible onset of a malarial attack, and that careful examination of both thick and thin films of their blood has yielded a negative result.

July 29th: The patient at St. Mary's had a temperature of 100° F. last evening and 102° F. this morning. The patient at the West End Hospital is also reported to have definite febrile paroxysms, indicating that the malarial attack has commenced.

July 31st: Volunteers attended, as requested. Blood films (thick and thin) were taken and carefully examined. In no case were parasites found, and no volunteer has felt any sign or symptom indicating a possible onset of malaria.

Aug. 5th: A third control case, infected at St. Thomas's Hospital by the bites of nine mosquitoes on July 17th, began his malarial attack on the 30th (incubation period 13 days), and a fourth (under Dr. W. J. Adie), infected by the bites of eight mosquitoes on July 20th, began his attack on Aug. 1st (incubation period 12 days). The control case at Horton, infected on July 20th, and given prophylactic doses of quinine before being bitten and daily for eight days thereafter, began to have febrile paroxysms from Aug. 1st (incubation period 12 days), but parasites have not yet been found in the peripheral blood. The mosquitoes used for infecting these and other control cases are those which bit the volunteers. Six volunteers attended to-day, and the remaining four (who were absent from London) will send their blood films and cards. No volunteer has felt any sign or symptom indicating a possible onset of malaria.

Aug. 7th: Blood films and completed cards of all volunteers have now been received and carefully examined. All blood films are negative, and no indication of malaria has been observed. In striking contrast is the fact that the control cases, infected by the same mosquitoes—namely, four persons who took no prophylactic and one who took quinine as a prophylactic—all developed malarial fever 14 days or less after infection.

Aug. 10th: To-day is the 27th day since the volunteers were infected. None has had any indication of malaria. On the 8th parasites were found in the blood of the patient at Horton, who, to serve as a control, was given quinine prophylactically for eight days, and she, as well as each of the other control cases, is now going through the usual malarial attack, with many parasites in the blood and quotidian or tertian rigors, during which the temperature rises to 105° F. or 106° F. The experiment may, therefore, be considered to have terminated.

Conclusion.

This experiment, and the 15 equally successful trials which preceded it, prove that plasmoquine effectively prevents mosquito-borne malarial infection among a group of healthy individuals who take the prophylactic doses. Quinine lacks this remarkable property. The successful result in the present test was obtained by taking 0·02 g. on the day before infection, and the same dose thrice daily on the day of infection and on the five following days, but, from the results of our previous tests, we know that somewhat smaller doses taken over a shorter period are equally effective. The next step should be to ascertain whether the preparation is effective when taken only once daily, and, if so, what may be the smallest daily dose which will prevent malarial infection in persons who are bitten by infected mosquitoes twice or thrice weekly over a prolonged period.

SWEEPSTAKES FOR HOSPITALS.—The Rev. E. J. T. Bagnall, secretary of the London Free Church Federation, recently sent a circular letter to 51 hospitals in Greater London, asking for their views on the desirability of raising money by means of sweepstakes. The Nose, Throat, and Ear Hospital, Golden-square, was the only institution which sent a favourable reply.

SUICIDES DUE TO GAS POISONING.—Returning a verdict of suicide while of unsound mind at an inquest at Hove on August 7th, on a single woman, aged 56, who was found gassed, Dr. E. F. Hoare, the coroner, commented on the fact that at the recent meetings of the British Medical Association at Eastbourne the question was raised as to whether it was possible to make the inhaling of gas obnoxious. Suicide by gas poisoning, he went on to say, was undoubtedly so easy and convenient that anyone who was a little unbalanced yielded to the temptation. If gas could be made more unpleasant to inhale its employment for self-destruction would probably be limited. In many cases, he added, if there were no gas at hand the suicide would have chosen no other form of death. On behalf of the gas company it was stated that the question would receive the consideration of the gas industry.

TOURNIQUET PARALYSIS.

A PLEA FOR THE EXTENDED USE OF THE PNEUMATIC TOURNIQUET.

By Nils L. Eckhoff, M.S. Lond., F.R.C.S. Eng.,
SENIOR DEMONSTRATOR OF ANATOMY AND LATE SURGICAL REGISTRAR, GUY'S HOSPITAL; SURGEON, ST. JOHN'S HOSPITAL, LEWISHAM.

Tourniquet paralysis is a sufficiently common complication of operations upon the arm and hand to warrant the careful consideration of every surgeon who is in the habit of operating on the limbs, yet I have been unable to find any reference to the condition in the English literature, and only one or two short articles in the French.[1][2]

The advantages of a bloodless field are so many that it is unnecessary to stress them here. The time lost in checking hæmorrhage is in itself a sufficient handicap to condemn any operation upon a limb that is not performed below a tourniquet. Yet there are surgeons who purposely refrain from using this aid, owing to the fear of inducing a tourniquet paralysis. What can be more disheartening to a surgeon than to perform an operation cleanly and simply with the help of a tourniquet, only to find convalescence marred by a paresis lasting throughout that critical period when voluntary active movements are so essential in the restoration of function?

Causation.

There are several possible factors in the causation of this calamity. It is difficult, at the outset, to assess the importance of the mere anæmia induced by the tourniquet upon the nerves themselves. From our knowledge of the sensitiveness of certain nervous structures to anæmia, paralysis of the nerves might be expected to follow at once upon the interruption of their blood-supply. Concussion of the brain—with immediate and complete cessation of function of the higher centres—is, according to most authorities, the result of sudden cerebral anæmia. Yet it is remarkable how little all the tissues of the limb—the nerves included—are affected in the vast proportion of cases where a tourniquet is used. As far as can be determined, the function of these structures is usually unimpaired by interference with their blood-supply for relatively long periods.

I have no knowledge of "ischæmic" contracture following the use of a tourniquet. This condition is, according to recent observations,[3] more likely to be due to venous than to arterial obstruction. The paralysis of nerves that occurs in 60 per cent. of cases of "ischæmic" contracture[4] is a secondary phenomenon, caused by the strangulation of the nerves in the inevitable fibrosis, and must not be confused with tourniquet paralysis. In the "ischæmic" cases the nerve paralysis comes on gradually, and can be, to some extent, relieved, if so desired, by freeing the encircling fibrous tissue.

Numbness of the finger-tips occurs fairly frequently after the use of a tourniquet. Numbness of the leg or of the forearm can be induced if the limb be kept acutely flexed for a long time, and passes off rapidly when normal posture is restored. These instances suggest a vascular phenomenon, as would also the case, recently brought to my notice, where a complete paralysis of the arms followed an operation for gall-stones, the arms being placed above the head during the operation. It is, nevertheless, probable, from the fact that most patients suffer no inconvenience after the application of a tourniquet, that anæmia of the nerves cannot be the sole cause of paralysis. The slow rate of recovery in a manifest case—two or three months—also indicates a graver lesion.

The time factor is by some held to be important. Forty-five minutes has been thought to be a safe limit, but from the fact that it is impossible to regulate other factors—such as the amount of the pressure applied—it is obvious that there is a wide margin of error. I have seen paralysis follow relatively short operations.

The type of the tourniquet has undoubtedly some influence. Most are agreed that the older thick rubber tube should never be used. A flat band, of the nature of an Esmarch's or Martin's bandage, seems safer, but, again, is not immune from serious consequences. It is true that paralysis does not follow with such readiness if the tourniquet is placed high up in the arm, so as to encircle the mass of the deltoid, or around the mass of muscles immediately below the elbow. I have, however, seen it in the former case.

The most significant fact in the study of this condition is that the paralysis is practically unknown in the leg. I have heard of only one case, and I have never seen one. In the leg the nerves are always, except where the common peroneal (external popliteal) crosses the neck of the fibula, relatively well covered and protected by muscular tissues, and nowhere come into close contact with the bone. In the arm, however, the neuro-vascular bundle can easily be palpated against the humerus along the inner side of the upper arm, and the radial (musculo-spiral) nerve runs in immediate contact with the humerus as it courses from the medial to the lateral side. This is the nerve usually affected in lesions due to the tourniquet.

The fact that the nerves are sensitive to pressure is well known. The axillary (circumflex) nerve is often affected in dislocations of the shoulder, and the radial (musculo-spiral) in "Saturday night paralysis." The ulnar nerve may be injured if the arm is left hanging against the edge of the operating table during anæsthesia, and is frequently compressed, even in the absence of vascular changes, by the fibrous band associated with a cervical rib. In some people if the arm is kept acutely flexed at the elbow with the hand at the back of the head, as when lying in bed, a tingling is produced in the hand, accurately corresponding with the area of distribution of the ulnar nerve. If the legs are kept crossed for long, a similar tingling occurs in the distribution of the common peroneal, due to pressure on its trunk behind the neck of the fibula.

From these considerations it seems almost certain that the paralysis following the use of a tourniquet is due to the effect of the direct pressure of the encircling band upon the nerves, pressing them against the bone, and not to any extent to the effect of a simple anæmia. This is borne out by the peculiar sensitiveness of the radial nerve, fitting in so well with anatomical considerations and so difficult to explain by any vascular process.

An explanation must also be found for the fact that the sensory fibres in a mixed nerve trunk suffer less than the motor fibres. Sherren[5], in his description of "incomplete nerve injuries," denies this dissociation, but the present series of cases show it clearly. It has been stated by Stoffel[6] and others that there is an exact grouping of the nerve-fibres in a mixed nerve, and that the sensory fibres run in the middle. This might suffice to explain why the sensory fibres recover soonest, or even escape damage, in a tourniquet lesion. But Stopford[7] stresses the evidence of Heinmann, Compton, Borchardt, and Wjasmenski, and

ANÆSTHESIA IN THE SECOND STAGE OF LABOUR IN PRIMIPARÆ.

BY JANE KING, M.B. LOND.,
AND
JOYCE MORGAN, M.D., B.SC. LOND.,
RESIDENT ANÆSTHETISTS, THE MOTHERS' HOSPITAL, CLAPTON.

THE importance of anæsthesia in the second stage of labour is becoming more generally recognised and this investigation, as far as it has gone, suggests that there is at least one anæsthetic which can be used with absolute safety and efficiency. All the cases of this series were primiparæ. Gas and oxygen were given as a routine to all primiparæ with any degree of toxæmia, so that all the least favourable cases were included in the gas and oxygen group. For the remaining cases the anæsthetic was chosen at random. The figures for ether anæsthesia were taken from only 18 cases, and are given for what they are worth, ether having proved an unsatisfactory anæsthetic in the second stage of labour.

In each case a record was kept of the character, duration and frequency of the pains, the pulse-rate, and fœtal heart-rate, and the condition of mother and child after delivery; observations were taken every 15 minutes throughout the second stage. In the majority of cases some sedative—e.g., potassium bromide and chloral—had been given in the first stage, but the effect of such drugs had usually ceased to be evident before the anæsthetic was administered. It was impossible to estimate the effect of the anæsthetic on perineal lacerations, owing to the fact that deliveries were conducted by pupil midwives. Again, owing to the different factors operating, it was difficult to estimate the effect of anæsthesia upon hæmorrhage.

METHOD.

Anæsthesia was commenced at the beginning of the second stage of labour. A mixture of nitrous oxide, 4 parts, and oxygen, 1 part, was given first, the proportion of the two gases being varied to suit the needs of the individual patient. The patient was instructed to take two deep breaths of the mixture at the beginning of each pain, administration being continued throughout each contraction. Towards the end of the second stage, deep anæsthesia was required, and the anæsthetic was continued between the pains. The percentage of oxygen was also increased at this point, because if the patient were allowed to become cyanosed there was a chance of the infant being rather blue. In a few cases a little ether was added to the mixture during the birth of the head.

For these investigations a McKesson's portable apparatus was used, and was found very easy to control.

Comparison of Anæsthetics.

Other anæsthetics used in this series were: (1) chloroform (40 cases); (2) ether (18 cases); (3) chloroform 2 parts, ether 3 parts (20 cases). The effects of these anæsthetics, as compared with those of gas and oxygen, in the second stage are interesting, and are best shown by a series of tables.

Relief of pain was evident in all cases, and there was seldom any difficulty in persuading the patient to take the anæsthetic. Usually with gas and oxygen the patient was unaware that the baby was born, but in two cases it had no effect on the pain, and another anæsthetic had to be used. In a few cases the patient was difficult to control towards the end, but this difficulty diminished with increasing skill in administration.

TABLE I.—*Effect on Contractions.*

Anæsthetic.	Frequency of contractions.			Length of contractions.		
	Less frequent.	Same frequency.	More frequent.	Shorter.	Same length	Longer.
Chloroform ..	18	22	14	3	29	21
Ether	12	5	3	1	7	12
C_2E_3	7	6	6	6	5	8
Gas and oxygen ..	8	35	46	6	35	48

With gas and oxygen the length and frequency of the contractions were increased in 50 per cent. of cases (Table I.). Accessory muscles were used more freely when the appreciation of pain was dulled. With ether the length of the contraction was increased in 60 per cent., but the frequency was diminished in 60 per cent., and in all cases the time interval became very irregular.

TABLE II.—*Length of Second Stage.*

Anæsthetic.	1 hour.	1–2 hours.	Over 2 hours.
Chloroform	27	20	5
Ether	7	7	5
C_2E_3	10	8	—
Gas and oxygen	64	30	6
No anæsthetic	32	56	12

Of the gas and oxygen cases lasting over two hours, five were abnormal, two being extended breeches, one a contracted outlet, one a rigid perineum, and one a distended bladder. There was a definite decrease in the length of the second stage with gas and oxygen anæsthesia compared with the length with other anæsthetics (Table II.). Fifty cases of primiparæ in which no anæsthetic was used showed a further increase in the length of the second stage. Accessory muscles were not used so well with other anæsthetics as with gas and oxygen, because with diminished perception of pain there was also a certain degree of muscular relaxation. With ether it was difficult to get beyond the excitable stage and still maintain the contractions, so that the patients were difficult to control.

After-effects.—With gas the patient was quickly round. With chloroform and ether the patient was drowsy at the end of the second stage and took some little time to recover from the anæsthetic. Vomiting was not uncommon, because many of the patients came into hospital in labour, directly after a heavy meal. Vomiting with gas and oxygen anæsthesia was very rare. The effect on the pulse-rate, as an indication of exhaustion, is shown in Table III.

Gas and oxygen compares very favourably with other anæsthetics, in spite of the fact that this group contains 17 cases of toxæmia, in whom obstetric exhaustion is always inclined to be more severe. In 86 per cent. of cases the pulse-rate either dropped or rose only ten extra beats per minute.

The effect on uterine contraction, as shown by post-partum hæmorrhage, can only be suggested by the following figures, for it must be remembered that there are many other factors besides the anæsthetic which are responsible.

TABLE III.—*Pulse-rate.*

Anæsthetic.	Rate dropped.	Un-changed.	Up 10 beats.	Up 20 beats.	Over 20.
Chloroform ..	15	17	12	3	5
Ether	4	5	3	5	2
C,E, ...	7	4	4	3	—
Gas and oxygen	20	35	16	7	4

Hæmorrhage Exceeding 20 oz.

Chloroform.—3 cases.

Ether.—2 cases (one case due to retained placenta).

Gas and oxygen.—2 cases (one case due to retained placenta and one to severe toxæmia).

The *effect on the child* is suggested by Table IV., but it must be remembered that the skill of the midwife is a large factor in the condition of the child at birth. It is a common fault for the pupil midwife to hold the head too long on the perineum, and a certain percentage of cases of blue asphyxia are due to this cause.

TABLE IV.

Anæsthetic.	Cyanosed but crying at birth.	Blue asphyx.	White asphyx.	Drowsy and full of mucus.	Norm.
Chloroform ..	—	7	1	2	40
Ether	—	3	2	1	13
C,E, ...	—	1	—	—	17
Gas and oxygen	10	4	2	2	82

There was one stillborn infant in the gas and oxygen series, death being due to a tentorial tear.

Of the four cases of blue asphyxia with gas and oxygen anæsthesia, all were abnormal labours, and one case of white asphyxia was an extended breech. It must also be remembered that the infants of toxæmic parents are included in the gas and oxygen group.

Summary.

There are definite advantages in the use of gas and oxygen in the second stage of labour, which may be summed up as follows:—

1. Relief of pain.
2. Uterine contractions increased in length and frequency in 50 per cent. of cases.
3. Second stage of labour shortened.
4. No deleterious after-effects on the mother.
5. No serious effects on the child. (Slight cyanosis is not uncommon, but is seldom associated with apnœa).
6. Anæsthetic pleasant to take and easy to give, and depth readily controlled.

Two *disadvantages* must be noted, both of which may be summed up in the word "expense." Special apparatus is required, and the average cost per patient is about 2*s*., as opposed to 3*d*. for chloroform. The services of an anæsthetist are required throughout the second stage.

In conclusion we should like to thank Lady Barrett for originating this research, and for the interest she has shown throughout.

AN UNUSUAL CASE OF HODGKIN'S DISEASE.

BY J. I. SAPWELL, M.B. CAMB.,
LATE HOUSE PHYSICIAN, KING'S COLLEGE HOSPITAL.

THE following case of Hodgkin's disease presents a number of unusual features, any one of which is remarkable in its own way; occurring all together they appear to form a unique combination.

A married woman of 55 was admitted to King's College Hospital under the care of the late Dr. F. W. Tunnicliffe on Jan. 13th, 1927, complaining of "fluid in the stomach," which she stated had come on nine weeks previously. There was ascites and œdema of the legs. The glands in both axillæ and both groins and at the occiput were enlarged. There was a hard nodular mass (possibly glands) in the right hypochondrium and there was dullness on percussion over the mediastinum in front. The liver dullness extended up to the fourth rib but the lower edge of the liver could not be felt because of the distension. On a subsequent occasion the liver was found to be enlarged an inch below the costal margin. The spleen was palpable. The abdomen was tapped several times, about 18 pints of chylous fluid being withdrawn on two occasions. The pathological report on one specimen of the ascitic fluid showed a fair number of cells, of which 90 per cent. were lymphocytes, and a fat content of 0·26 per cent. Blood counts showed a slight secondary anæmia, with some increase in the large mononuclears, which varied from 7·6 per cent. to 16 per cent.

About two months after admission the patient developed pleurisy with effusion on the left side, and turbid yellow serous fluid, containing about 25 per cent. total protein, was removed by aspiration. The patient's general condition subsequently improved, the pleural and peritoneal effusions did not reaccumulate, and she left hospital on April 23rd, 1927, the provisional diagnosis being lymphadenoma of the "deep" type—that is, affecting the deep lymphatic glands predominantly.

For the next 12 months she attended hospital as an out-patient, during which time her general health was poor and she had a troublesome cough with occasional vomiting, but the ascites did not recur.

She was readmitted to hospital, after an interval of a year, on April 27th, 1928, complaining of fluid in the chest, abdomen, and legs, also of cough, nausea, general weakness, and dyspnœa. She stated that her relapse had started three weeks previously. On examination there were physical signs of fluid in the right side of the chest extending up to the level of the second rib in front. No enlarged glands were felt in the neck or axillæ. There was ascites, the liver was slightly enlarged, and the left leg was œdematous.

On April 28th and May 15th the abdomen was tapped, 14 pints of chylous fluid, having approximately the same composition as before, being drawn off on each occasion. On May 4th the right side of the chest was aspirated and two pints of chylous fluid removed. The pleural fluid contained many leucocytes (mostly lymphocytes), a few red corpuscles, 12 per cent. protein, and 0·3 per cent. fat. Culture was sterile. On May 24th the patient had an attack of paroxysmal tachycardia lasting rather less than 12 hours, and another similar attack occurred six days later. On June 1st enlarged glands were felt in both axillæ and in the left groin, and the mediastinal dullness on percussion was increased. On June 5th a small lymph-gland was excised from the chest wall just below the right axilla and sent for microscopical examination. On June 7th the patient had suppression of urine, and passed no more urine up to the time of her death a fortnight later. The œdema increased, the thighs and lower part of the abdominal wall becoming very swollen. The blood-urea on June 11th was 119 mg. per 100 c.cm. and on June 20th it had increased to 197 mg. per 100 c.cm. In spite of this the patient's general condition remained remarkably good and, though somewhat drowsy at times, she was usually bright and cheerful, uræmic manifestations being on the whole completely absent.

She had eaten a good midday meal, chatted brightly to the other patients, and amused them by singing on the day before her death, which occurred quite without warning; she collapsed suddenly and died on June 22nd.

At *autopsy* milky fluid was found in both pleural cavities. The entire parietal pleura on the right side and the diaphragmatic pleura on the left were infiltrated, forming a thick pinkish-grey sheet of tissue with a nodular surface. The visceral pleura over the lower lobes of both lungs was similarly affected, in one place being more than an inch thick. The underlying lung was collapsed, but not invaded. There be justified by the desperate state of the patient. But I was warned by my colleagues to refrain from this heroic method, as they had witnessed fatal issues in all cases in which intravenous quinine was given. I am surprised that authors still recommend such a course. The supposed power of quinine to break up the obliterating and damaged erythrocytes in the cerebral capillaries is not actually beneficial. The liberated schizogonts can infest healthy erythrocytes and continue their deleterious effect on the brain.

My first four cases of malarial coma died, for I was a novice, and could do nothing to help them. At the fifth case I was struck by a new idea. Considering the encephalitic and meningitic varieties of malarial coma, I decided to try the administration of urotropine intravenously, in the hope of abolishing it. I remembered the power of this drug to pass the barrier of the cerebro-spinal fluid, so that it was recommended by pædiatrists and neurologists in the treatment of leptomeningitis. Recently Paul Rostock[1] wrote a monograph on the treatment of meningitis with urotropine, and on the various modes of its administration. I also took into consideration the capacity of this drug for elimination in the secretions of the liver and kidneys. The course of the drug is exactly that of the malarial parasite, and it should apply its bactericidal potency in just the necessary places.

I therefore injected into my fifth comatose patient 3 c.cm. of a 40 per cent. solution of urotropine, sterilised by a brief period of boiling. The effect was astonishing. All the serious cerebral symptoms began to evaporate slowly, and had completely passed off in three hours. The stuporose state in this and several more cases, and the convulsions in others, wholly disappeared. The pyrexia and the other signs of quiescent malaria, and the parasites in the blood, remained as in an ordinary case, thus showing that the urotropine does not damage the parasite directly. Its effect depends only on sweeping the capillaries of the brain and the secretory canaliculi of the liver and kidneys.

My own belief, which still needs direct experimental confirmation, is that the purification of the blood capillaries is brought about by the fixing power of the formaldehyde produced from the urotropine. This fixative potency raises the specific gravity of the damaged erythrocytes, hinders their adherence to the walls of the vessels, and facilitates their passage.

In this paper I have no intention of wearying the reader with reports of cases. I only wish to emphasise that all the symptoms of the comatose or convulsive state disappear after three to six hours, and that the patient becomes a normal malarial case with a mild course and favourable prognosis. I have observed this effect of intravenous urotropine in ten cases, all of which recovered from coma and eventually from malaria with the usual therapy.

SUMMARY.

In all cases of malarial coma, or any other acute involvement of the central nervous system in malaria, the intravenous injection of urotropine is the surest remedy to convert the severe state into a mild one. The urotropine exercises its salutary effect *loco dolenti*, in the cerebral capillaries and in the cerebro-spinal fluid, passing through the choroid and meningeal barrier.

My experience was gained four years ago, during an annual practice in the sub-tropical country of Tagykistan, at the city of Doshambe.

PSYCHOSIS IN OSTEITIS DEFORMANS.

By W. J. Rutherfurd, *M.C.*, M.D. Glasg.

Dr. S. J. Hartfall's paper,[1] in which he upholds the rarity of mental symptoms in osteitis deformans, leads me to report the following case in which they were present :—

On Dec. 12th, 1925, a patient of mine, a man aged 62, sent for me. I found him in bed with the right thigh in plaster. He told me that he had fallen at his work 30 days previously, and had been taken to hospital with multiple fractures of the pelvis and of the thigh. He had come out with no evidence to confirm this diagnosis, and I had received no message about him from the hospital, on his discharge with his limb in plaster. I communicated with the hospital, and was informed that he had been admitted with fracture of the neck of the right femur (not of the pelvis at all), and that radiographic examination had revealed a condition of the bone suggestive of osteitis deformans.

A courteous letter (dated Jan. 11th, 1926) from the house surgeon went on to say :—

> "Further X rays of other bones were therefore taken (which I suppose led him to believe that he had multiple fractures), and these revealed changes in the skull, tibia, radius, spine, and pelvis, to a greater or less degree, and confirmed the diagnosis. Careful investigation of the history gave the stooping, pains in the back, and bowing of the legs, but not the increase in size of hats. . . .The ribs are, fortunately, not involved to any extent, and he gave no signs of chest trouble while here."

This man is still alive, and is now 71 years old. He is of low stature and shambling gait, with very definite bow legs. Of his two children, his son is in the ranks of the permanently out of work, and married after being a non-worker for many years ; his daughter has exophthalmic goitre, and married an out-of-work labourer of peculiar disposition, who, shortly after marriage, took to his bed for no obvious cause, remaining there until he was removed to the mental ward of the local workhouse hospital in January, 1927. There he was certified, and was removed to the county asylum, where he has remained ever since. With a descending heredity such as this it is impossible to be certain that, in the absence of osteitis deformans, this patient would himself have kept free from mental changes on attaining his present age.

Brief notes were, from time to time, taken over the past six years, and these may, perhaps, be allowed to speak for themselves without the addition of any running comment.

Jan. 20th, 1926.—No albumin or sugar in urine.

March 16th, 1926.—Sends urgently for a special visit, but, when seen, refuses to say what he wants or how he feels, except for the reiterated phrase, " very low." Examination entirely negative.

July 19th, 1929.—Says he trembles from head to foot since his wife's death in May of the present year. (He had her attended by another doctor, by the way.) Only slight tremor of hands. Knee-jerks normal. Thickened radial artery.

Aug. 5th, 1929.—Says his condition is urgent, and that he feels " right down ill," but either will not, or cannot, supply particulars.—Aug. 13th.—Again complains of being " very ill." Says that he feels all right sometimes, but that, as soon as he gets to his work in the mornings, a feeling of illness comes over him. Later in the day is seen striding along in the street at 10 P.M., going in a direction away from where he lives.—Aug. 21st.—Comes for treatment outside surgery hours, saying that he is " very ill."—Aug. 29th.—Is strange in his manner and incoherent in his speech.

Sept. 6th, 1929.—Says that he often feels irritable and miserable.—Sept. 9th.—Brings back his medicine, complaining that it causes him to have palpitation.—*Sept. 16th.*

---

[1] THE LANCET, July 11th, p. 68.

—Says he is "downright ill with one thing and another." When asked what he means, he says that I have had him under my care for a good while now, and ought to know what is the matter with him without his telling me. I then ask him how he is feeling to-night, and his only reply is, "very poorly." A complete deadlock!—Sept. 23rd.—Will not take his medicine.

Oct. 21st, 1929.—Still complains about the way I am treating him. On its being suggested that he might care to attend the out-patient department of a local hospital, he says that he might get "better attention" there than I am giving him. He then suggests that I could, if I cared, do something more for him if he were a private patient than I am doing for him as a patient under the National Health Insurance.—Oct. 25th.—Has an inferiority complex with a delusion of persecution—the persecutor being myself.

Nov. 1st, 1929.—Appears with his National Health Insurance medical card in the surgery to-night, and asks for legal advice, saying that he "thought that I was a solicitor." —Nov. 4th.—Still haunts the surgery, and is obsessed with the idea that he is receiving inferior treatment because he is not a private patient.—Nov. 25th.—Says his medicine is "noxious," and refuses to take it. His objection is to its taste.

Dec. 2nd, 1929.—Has thrown his medicine away, although, to pacify him, he had been supplied gratuitously with a private supply.

June 20th, 1930.—Has a perionychia, and refuses to allow a septic bulla by the side of his finger-nail to be clipped away. —June 27th.—Has been tampering with his dressings.

Feb. 3rd, 1931.—Is still attending for treatment, complaining of all sorts of minor discomforts.

Aug. 9th, 1931.—Seen to-day, bringing the story up to date.

It is obvious that this man is in a perpetual state of vague discomfort; and at his age one almost feels tempted to promote euphoria by the use of one of the available habit-forming drugs. So long as he remains outside an institution it has seemed wiser not to adopt any such means of giving him comfort.

One records a history like this somewhat apologetically, in view of its obvious shortcomings. If, however, the subject is of importance at all it would seem justifiable to place such a story on record. It may also serve a useful purpose in reminding those who are apt to forget such matters of some of the real difficulties encountered in the every-day treatment of patients under the National Health Insurance Acts.

Manchester.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

SECTION OF ANÆSTHETICS.

AT the first meeting of this section on July 22nd the chair was taken by Dr. H. P. FAIRLIE, and subsequently by Dr. LANGTON HEWER. A paper on the

Progress of Anæsthesia

was read by Dr. R. J. CLAUSEN. The public, he said, believed that great advances had been made in anæthesia during the last decade or two. Their flattery was hardly justified if their anæsthetic was ether or chloroform on a mask; the resources at the command of the anæsthetist had considerably increased, but full advantage had not been taken of them. The standard in the large teaching hospitals was probably fairly high, but there was at times an unfortunate tendency for some new technique to be used exclusively in the hospital of its origin. It was essential that the surgeon should realise the importance of the anæsthetist's work, as they could make little advance without his interest and coöperation. Routine anæsthesia might be bad anæsthesia, but a good deal of routine was necessary for smooth work. Any one anæsthetist's standard technique might make little difference to healthy patients undergoing short operations, but a large proportion of cases were not so favourable and needed special adaptation. There was a striking lack of regard for the patient as an individual. In hospitals he was often almost lost sight of. His pillow was removed, and he was left in great discomfort, flat on a metal-topped table, with only a thin blanket underneath him, just at the time when he should be made easy and comfortable. Post-operative backache, headache, and even chest complications might be much reduced if every nurse were dressed and towelled for operation and laid on the table for an hour or two. A tendency sometimes appeared for the theatre to become a stage, on which the star performer displayed his skill, supported by leading lady, minor characters, and chorus, the anæsthetist being expected to supply the comic relief.

The mask and drop bottle were still employed far too often; their use should be limited to induction. Open ether had been described as a method invented by amateurs for amateurs. Local, regional, and spinal methods were not as fully used as they might be, nor were the advantages of gas, notably ethylene, exploited adequately. The gas apparatus available in England had tended to hinder the effective adoption of the method. People complained that the modern apparatus was too complicated; but they did not make that complaint of their motor-cars.

Wherever possible, in major or minor surgery, gas-oxygen should be preferred to ether alone, and, when circumstances did not forbid, ethylene should replace nitrous oxide. The fullest use should be made of combined methods. Ethylene was little more liable to explosion than oxygen-ether. For long oral operations intubation was necessary, but endotracheal insufflation was not to be recommended. The necessity for adequate premedication was not fully realised; morphia was essential in gas-oxygen, and no patient should come to operation without preliminary sedatives. Carbon dioxide and intravenous glucose should be more widely used. There was a striking lack of any serious attempt to investigate the problems of anæsthesia by means of observations on large numbers of cases. There was a considerable personal equation in inhalation anæsthesia—hence the wide diversity of agents, apparatus, and techniques, all with good results.

The reasons for the shortcomings of anæsthesia, said Dr. Clausen, were traditional and economic. Hospital and national customs died hard, and hospitals and anæsthetists alike could ill afford expensive modern apparatus. Nursing homes were often entirely devoid of equipment; consequently portable and simple—even crude—apparatus was used. Progress could only be achieved through the recognition by all concerned of the importance of anæsthesia as a subject. Its status must be maintained and improved. The standard of asepsis must be as rigid as possible. The position of the anæsthetist as a specialist must be made secure, and his services fully utilised in all cases. The demon of hustle must be exorcised, and the tyranny of long lists broken.

DISCUSSION.

Dr. K. B. PINSON spoke strongly in favour of ethylene, commenting on the absence of shock and after-effects. It was not potent enough to control some patients, and ether might have to be added. Attendants complained of the smell, but the patients never did. He used the nasal method, giving nitrous oxide, oxygen, and ethylene in sequence, and had and those in which the infection reacted from a sinus or infected teeth.

Mr. Herbert Tilley said that pain might be due to swelling of a band of tissue behind the tongue, which was red and raised, and in his opinion was not always due to sepsis.

Mr. C. A. Scott Ridout considered that this band was a frequent cause of pain, but thought it due to sepsis. Sometimes an anatomical peculiarity, such as a long styloid process, predisposed to pain.

Mr. H. V. Forster, Mr. J. A. Gibb, and Mr. Lowndes Yates also spoke; and Mr. Bedford Russell replied.

Mr. Musgrave Woodman opened a discussion on the

Treatment of Carcinoma of the Œsophagus.

He considered first the reason of the total failure of our present means of treatment to effect a cure, and pointed out that this in part depended on the free anastomosis of lymphatic channels in this region, and in part on the mobility of the œsophagus, which limit the formation of a zone of adhesions adequate to prevent the spread of sepsis from the lumen of the gullet to the thorax. In cases in which the cancer was limited to the cervical part of the œsophagus, he advocated its excision. In patients in whom the cancer lay within the thoracic segment of the œsophagus, he condemned all methods which demanded opening of the thorax as being too severe for these debilitated patients. For cancers of the thoracic segment, he advocated diathermy, on the grounds that it was a painless operation, which increased the lumen of the gullet and gave an increased ease of feeding, although it never cured. The interstitial application of radon, he thought, had failed, because the upper portion of the growth alone was treated. The central implantation of radium was the treatment that he advocated. He attributed part of the failure to secure more fortunate results to the irritation of the metal tubes in which the radium was carried. He had therefore caused to be made tubes of soft rubber. These he showed, and later, in discussion, members expressed approbation of their design.

The President voiced the feeling of the meeting in expressing their regret that Sir Charters Symonds, the pioneer of treatment of œsophageal cancer, could not take part in the discussion. Mr. Mollison agreed with Mr Woodman that diathermy would not cure, but it relieved dysphagia. He advocated gastrostomy, and had knowledge of an exceptional case in which dysphagia due to œsophageal carcinoma was relieved, and the patient swallowed comfortably till he died of a recurrence five years later.

Mr. Scott Ridout gave details of a case in which a great regression of a growth had taken place. He also advocated gastrostomy, which he does as a routine under local anæsthesia.

Sir James Dundas-Grant advocated early gastrostomy. He referred to perforations of the œsophagus after using radium, and thought that Mr. Woodman's tubes would go far to diminish their occurrence.

Mr. Davis stated that the radium results were worse in œsophageal cancer than in any other site of carcinoma.

Mr. Woodman, in reply, said that although treatment by radium held the field to-day, diathermy should not be given up, for, after its employment, the patient often swallowed better than after any other form of treatment. He believed in small amounts of radium at a considerable distance from the growth. Large doses gave bad results. He disagreed with the performance of gastrostomy as a routine. He had used it largely in the past, but now had almost dropped it, for he found that the mental effect upon the patient was so bad.

Mr. Horgan read a paper on

Development and Anatomical Peculiarities of the Upper Jaw

in Relation to the Surgery of the Nasal Sinuses. He referred briefly to the work of Keith and Campion on the development of the upper jaw, and emphasised their bearing on the conventional forms of operation for chronic nasal sinus disease. It was on the points brought out in this work that he based his belief that the most adequate line of approach to the antrum, ethmoidal, and sphenoidal sinuses was by the canine fossa route.

Mr. Bedford Russell suggested that the transantral route of attack on the ethmoids had a good deal to recommend it. It formed, in his opinion, one of the few examples of cases in which it was better to open the antrum from the mouth in preference to the nose.

Mr. O'Malley said that he had never tried the method which Mr. Horgan advocated, and was personally satisfied with the methods of approach by intranasal routes.

Mr. Tilley considered that antral inflammations could be divided into two—namely, the isolated antra, with a localised infection in which he advocated drainage by the intranasal route, and, secondly, the cases in which general polypoid degeneration of the nasal and antral mucous membrane had taken place. In these the buccal route was, he thought, preferable.

Mr. Forster recommended the intranasal route for opening the antrum, and found that local anæsthesia was adequate for the purpose.

Mr. Gibb spoke of the importance of preliminary intranasal medication before the operation, and Mr. Horgan replied.

Sir James Dundas-Grant read a paper on

The Nasal Element in Spasmodic Asthma,

in which he advocated treatment of the nose, which was frequently the peripheral source of the hyperexcitability of the vago-accessory nucleus. He pointed out that other conditions, such as a susceptibility to foreign proteins, a peripheral stimulus from some other region than the nose, or psychic disturbances, also caused hyperexcitability of this centre, and stressed the need of careful differential diagnosis of the cause of asthma. He considered that the nasal element was an important one in asthma, in support of which he cited the commonness of nasal abnormalities in cases of asthma, the improvement following the removal of these abnormalities, the return of the asthma when the nasal abnormality recurred, and the lessening of the hypersensitiveness to the foreign protein after nasal treatment. He found that when the asthma was of nasal origin the lesion generally lay in relation to the upper and back part of the septum. Operative treatment in children gave, in his opinion, specially good results.

Mr. Bedford Russell cited examples of difficulties that might arise in diagnosis.—Mr. C. A. B. Horsford advocated that operation should be of a thorough nature, or it would fail.—Mr. Horgan spoke of maxillary and ethmoidal sinusitis as a cause of asthma.

By SYDNEY SMITH, M.D., M.R.C.P., D.P.H., Regius Professor of Forensic Medicine, University of Edinburgh; and JOHN GLAISTER, Jun. London: J. and A. Churchill. 12*s*. 6*d*.

Two of this important series of medico-legal text-books take origin from the University of Chicago. Mr. Brothers' volume is written by a lawyer for doctors, and aims at being little more than an exposition of the law of the United States as it affects the medical practitioner. The medical sections are, indeed, so antiquated that one might easily overlook the merits of a work which contains a large amount of valuable information in a small space. The student of forensic medicine will note with interest how closely the American courts have kept to the English in developing the legal principles from which both systems derived. In some respects American courts appear to be harsher to the doctor—e.g., in awarding damages for negligence or for unauthorised operative interference. On the other hand, our American colleagues escape more lightly in actions for breach of professional confidence. An important difference has arisen in respect of the law of insanity. The doctrine of the "uncontrollable impulse," still regarded here as a heresy, has been accepted in most States of the Union. Laws against abortion also show deviations, for in some States it is not held to be a crime unless the woman has quickened, and in all statutes dealing with the subject explicit exemption is granted in cases "where premature delivery is necessary to save the mother's life." This statutory protection for therapeutic abortion (unknown to English law) has had a curious effect. The majority of courts hold that the onus is now on the prosecution to prove the *absence* of a medical necessity for the operation, with the result that the law is, in practice, almost a dead letter. It is consoling to observe that America is struggling, like ourselves, with anachronistic laws on Sunday observance—but, again, with a difference. We forbid recreation on the Sabbath Day, and they forbid work. The doctor, one learns with mingled feelings, is considered exempt from these restrictions.

More ambitious in scope is Prof. Webster's new text-book. The writer's personal interests appear to be mainly concerned with chemistry and toxicology, and these subjects have been allowed to occupy more than half a text-book which professes to cover the "usual phases of legal medicine." They are fully and competently treated, and the section on alcohol is particularly useful. It contains much important information about the effects of prohibition, and good descriptions of alcoholic poisoning. Certain important branches of medical jurisprudence are inadequately handled; with the result that the value of the book to students is much impaired. The section on "wounds and injuries" devotes only a few lines to "regional wounds" and little more to hæmorrhage. On the all-important subject of medico-legal autopsies and reports, the author blandly observes, "we have nothing to say, as we prefer to refer for such details to the articles of Helstoen, Le Court, and Lorries." In this volume of 830 pages there are only 49 illustrations, and of these only one (a badly smudged reproduction of finger prints) is original; the remainder are taken from well-known text-books. More surprising is the entire absence of original case material from a book which is remarkably well documented and rich in references to current literature. Unless Chicago has been cruelly maligned, a magnificent opportunity for practical research has been neglected.

Prof. Glaister's familiar text-book is conspicuously strong at the points where Prof. Webster's is weak. The section on post mortems and reports is in the best traditions of the Scottish schools, which have always grounded their students well in these important respects. The chapter on finger-prints is a treatise in itself, not to be equalled in any similar text-book. The greatest strength of the book, however, lies in the unique mass of case material which the older professor has accumulated in a long career in Scotland, and which his son has more recently enriched from Egyptian experience. Details of recorded cases are particularly valuable to the medico-legal expert, who has to work out relationships of cause and effect in obscure circumstances, with, perhaps, a man's life hanging on his estimate of probabilities. Here we have in detail the stories of classic crimes, with their morals made clear for future generations of experts. In the section on toxicology, the tests are well described and the information is up to date. It is difficult to run such diverse legal systems as those of England and Scotland in double harness in the confines of one volume; and it cannot be said that the authors have always been entirely successful. The section on incest, for example (p. 518), leaves the English law on the subject in considerable doubt. The legal age for marriage is incorrectly stated on p. 437. The most serious defect, however, is the absence of all mention of the Mental Deficiency Act, 1927, and the Mental Treatment Act, 1930, an omission which renders the chapters on these subjects misleading to English students. In a future edition some of the luxuriant growth of minor case records might well be pruned to make room for more up-to-date references to legal enactments and decided cases. With the medical aspects of their subject the authors have kept well abreast.

The small and modestly named volume presented by Profs. Sydney Smith and Glaister, Jun., is in reality a collection of valuable monographs on some of the most difficult problems confronting the medical jurist. Its very technical character will make it useful to Sherlock Holmes rather than to Dr. Watson, but its lucidity of style should enable even the cross-examining barrister to pick up invaluable hints. The amount of detailed learning on the examination of projectiles, of powders, and of weapons is astonishing. Full tables are given, showing particulars of every auspices ROEHL's method is being practised on a considerable scale at Cambridge and elsewhere.

The results of the present experiment, and of others now being conducted at Horton, should also have a noteworthy influence on future antimalarial policy in the world generally, for they indicate that, from now onwards, chemoprophylaxis and chemotherapy may play a larger part in the control of malaria than they have done hitherto. Everyone will remember that, after Ross's discovery of the mosquito cycle of the malaria parasite, KOCH, and later GRASSI, believed that the best hope of overcoming the disease on a large scale lay in an endeavour to break the epidemiological chain by treating the human host, rather than by measures aiming at destroying the insect carrier. That view has since received support from the success which has attended chemotherapeutic campaigns against kala-azar and bilharziasis, but, as regards malaria, field experiments on a similar plan have always failed because taking quinine, although it cures developed attacks, does not prevent either man or mosquitoes from becoming infected. If it is true that, in addition to quinine, a drug has now become available which, when taken in non-toxic doses by healthy people, prevents their infection, and when taken by malaria patients prevents the development of the parasite in the mosquitoes which feed upon them, it is reasonable to suppose that a repetition of KOCH's chemotherapeutic field trials might have a very different result. On a smaller scale, of course, the benefits of a drug which prevents malarial infection are clear. For example, malaria is the cause of much sickness and many deaths among the officers, crews, and passengers of ships trading to Africa, India, and the Far East. During the years 1918 to 1921 there were at least 20 deaths of seamen from acute malarial attacks during homeward voyages from those countries, and at least 65 from recurrences after arrival in England. In one line of steamers trading out of Liverpool no fewer than 531 cases of malaria occurred in the course of 12 months, and instances are on record in which, during homeward voyages from Africa or India, the disease attacked all except two or three of the whole ship's company. As these merchant ships seldom stay more than a few days and nights in malarious ports, it would be easy to arrange for all concerned to take the prophylactic doses during those relatively short periods and for a few days thereafter.

It is worth while, in this connexion appositely, to explain, in the light of the new knowledge, a "prophylactic trial" of plasmoquine which Dr. OTTO FISCHER was deputed by the Institute of Tropical Diseases, Hamburg, to conduct in April, 1926, on a steamship sailing to the African Coast.[1] The details were arranged by Prof. MÜHLENS, but, not regarding the drug as a true prophylactic, he based them on the view that "although plasmoquine alone is inadequate as a therapeutic remedy in subtertian malaria, some result might be expected from its prophylactic use as cases would be treated in the incipient stage when parasites would be relatively few and easily destroyed." With this object the drug was given in large doses (0·059 g.) on three consecutive days each week, instead of in small doses daily, as should have been done if true prophylaxis was the aim. The method left the 39 participating members of the crew unprotected on four days and nights of each of the nine weeks during which the trial lasted, and it is therefore not surprising that six cases of malaria occurred among them. It was claimed however, that this morbidity-rate (15 per cent.), indicated a successful result in comparison with the rates of 25 to 30 per cent. among the crews of two ships which followed the same route and on which the usual "quinine prophylaxis" was in force. Probably the correct explanation of the difference is that the plasmoquine taken by the crew on Dr. FISCHER's ship protected them against infection on three days and nights of each week, whilst the quinine taken by the crews of the other ships had no true prophylactic effect.

THE MANTLE OF FARR.

WE print in another column an appreciation of the work of Dr. T. H. C. STEVENSON from the pens of the Presidents of the Royal Colleges of Physicians and Surgeons, the President of the Royal Statistical Society, the President of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, and of two other distinguished men of science. It would be something of a work of supererogation to seek to add anything to what has been said by writers so well qualified to give judgment, and, in any case, it would be premature to write of the career of a scientific man who, we may fairly hope, will *still* increase the debt of gratitude we owe to him by further researches, as if it were at an end. Nevertheless, we may be permitted briefly to recall to the memories of our readers something of the history of the office which Dr. Stevenson has done so much to dignify.

The General Register Office is, in comparison with most of our public offices, a young department; it is not yet a centenarian. A century ago such vital statistics as this country possessed were, if anything, below the standard of those of other civilised communities. Within 40 years English official vital statistics were admittedly the best in the world, and this pre-eminence has never been lost. Everybody knows, or *ought* to know, that this great triumph was primarily due to the harmonious coöperation of a first-rate administrator, GEORGE GRAHAM, and a statistical genius, WILLIAM FARR. Scientific and literary powers were vouchsafed Farr in abundant measure, but these gifts would not have sufficed to establish an efficient public department, and some little meed of praise is owing from posterity to the forgotten administrator who made the department a going concern. Farr was succeeded in office by a man of a different type. WILLIAM

Ogle was, like Farr, a man of the highest character and public spirit, but, while Farr was a self-taught, energetic man of genius, knowing something of many subjects and without complete mastery of any one technique, Ogle was a highly educated, exact scholar, with the inhibitions and reserves that regular education imposes, and the publications of the department in his time lost something of the vivacity which Farr supplied. Ogle's successor, the late Dr. John Tatham, having the advantage of direct experience of public health administration under modern conditions which his predecessors lacked, effected noteworthy improvements, but even he hardly relieved the annual reports from a certain air of dryness which, in the opinion of some, is the appropriate quality of blue books. Under Dr. Stevenson's auspices this was changed. We do not mean that Dr. Stevenson reverted to the flamboyant method of Farr, and, like Farr and Silas Wegg, dropped into poetry, or, like Farr, made lists of odd surnames and speculated on their derivation. We mean that, like Farr, Dr. Stevenson looked upon the records as the raw material of research, and, using for the most part only the simplest of analytical methods, gave an impressive demonstration of the great and often forgotten truth that very simple methods, in the hands of a man of first-rate ability, will lead to discoveries which men of less ability, even if equipped with all the so-called mathematics in the world, are sure to miss.

We fear that few medical men read the annual reports of the Registrar-General. If more did, medical editors would receive fewer fallacious arguments for publication, and many journeys in search of mares' nests would never have been begun. Nobody has the excuse for neglecting these records of research that they are too mathematical to be intelligible. We can but hope that Dr. Stevenson may be able to use some of his leisure in bringing together into a separate volume his researches into the factors of infant mortality, a book which would at once become a standard treatise. Dr. Stevenson has, indeed, worn the mantle of Farr. When a man of great ability retires from office it is common form to say that his place will be hard to fill. In the present case the difficulty may well amount to an impossibility. Farr had so free a hand as an unofficial research worker, because, 80 years ago, official vital statistics had very little prestige, and important people or interests cared very little what was said by the Registrar-General or his subordinates. That is all changed, and although few really read the reports many use extracts from them as controversial weapons; hence there must inevitably be a tendency to prefer safety to brilliance, to discourage research, which, in the nature of things, cannot be safe. Dr. Stevenson has never been deliberately provocative, as Farr often was, but he has had a literary tact, if we may use the expression, which enabled him to say without provocation many true things not flattering to local or even national self-esteem. The task of his successor will not be an easy one. It will be hard to wear the mantle of Stevenson.

HYPERTENSION AS A SYMPTOM.

For some time it has been recognised that the symptoms associated with the earlier stages of hypertension—that is, before the onset of cardiovascular changes—are somewhat vague. That these diffuse symptoms of ill-health are due to the rise of blood pressure is rendered doubtful, because there is no correlation between the severity of the symptoms and the increase of tension, because the symptoms may often be relieved without reduction of the blood pressure, and also because definite hypertension may be found in people who regard their health as perfect. A year ago J. E. F. Riseman and S. Weiss[1] noted that the symptoms found in these early stages are very like those encountered in cases of psycho-neurosis with normal blood pressure. D. Ayman and J. H. Pratt[2] have now investigated a series of 100 patients, all of whom had a systolic blood pressure of 160 or more and no evidence of renal impairment; 17 of them were men, and 83 women. The commonest symptoms complained of were headache, pain, "nervousness," dizziness, fatigue, insomnia, and vasomotor disorders. The less frequent symptoms were widespread, and referred to all parts of the body. Further, these troubles were invariably multiple and of long standing, the average duration being over 10 years. Only four of these patients had no complaints. Ayman and Pratt next examined 50 psycho-neurotic patients of the same age as the others, but with normal blood pressures, and found that in this group the symptoms were almost identical, not only in character, but also in incidence, multiplicity, and duration. Passing on to inquire further into the onset of symptoms in the patients with high blood pressure, they ascertained that this often coincided with emotional disturbances or environmental difficulties. Ayman and Pratt were thus unable to differentiate between the symptoms associated with the early stages of high blood pressure and those of psycho-neuroses, and as evidence of a similar causation they remarked that so-called hyperpietic symptoms respond to removal of environmental difficulties, to sedatives, and to suggestion. A similar series of cases from which he draws the same conclusions is reported by D. Davis.[3]

F. R. Nuzum and A. H. Elliott[4] have tried to assess the part played by past illnesses, infections, and focal sepsis in the ætiology of hypertension. In those patients whose increase in blood pressure was associated with evidence of renal impairment they often found a history of scarlet fever and acute nephritis; but among those classified as "essential hypertension" the incidence of infection and focal sepsis was no greater than among controls. This investigation also suggested that there is no familial factor in the causation of high blood pressure, and that it is not unusually prevalent in patients with arterio-sclerosis of the larger vessels. Excessive obesity, however, was twice as common in patients exhibiting hypertension as it was in the control group. M. BACKER[5] too, after discussing the various drugs which have been lauded in the treatment of patients with a raised blood pressure, and after reviewing the various ætiological theories put forward by different workers, is forced to conclude that high blood pressure is not so much a disease as a symptom, which is found in people of abnormal nervous constitution and as a result of increased neuromuscular tonus of the arterial tree. The nervous factor in hypertension is also indicated, he says, by the great lability of the blood pressure, by which minor emotional upsets produce marked alterations of tension. The vegetative nervous system of the hypertensive patient reacts excessively to slight stimuli; mentally, this constitutional tendency manifests itself in neurotic symptoms, while in the cardio-vascular system it produces hyperpiesis. Ayman[6] has found that the blood pressure is liable to wide variations, particularly in patients with "essential hypertension," and in his most recent paper[7] he shows that this variation affects both the systolic and diastolic pressures to the same degree. The finding that the blood pressure, when observed sufficiently frequently and over long periods, exhibits these changes largely discredits many of the therapeutic effects claimed for various drugs, since, without very careful and frequent estimations before treatment starts, successful therapeutic reduction of the blood pressure may be simulated by minor changes due to emotion and environment.

ANNOTATIONS

THE SHORTAGE OF HOSPITAL NURSES.

WE publish as a supplement to-day the Second Interim Report of THE LANCET Commission on Nursing. It contains the questionnaire addressed to hospitals (printed in these columns on Feb. 28th) and a statistical and explanatory summary by Mr. Bradford Hill of the replies received. While comment on the document will not be expected from us, we may conveniently allude to the contents.

It is found that one-fifth of our hospitals fail to secure suitable candidates as sisters; one-half fail to secure the staff nurses and probationers of the standard they require. Nearly one-fifth of the full establishment of probationers leave annually, and it would seem that the hospitals must lose one-third of their annual entry, or in other words, more than one-tenth of their establishment of probationers without their becoming qualified. The improvised arrangements which are being adopted to meet the situation include the employment of temporary nurses, and the alteration of the educational standard. The report presents a picture of the nurse's life in hospital, her hours of work, her pay, her training, and her prospects, the arrangements for her recreation and holidays, her sleeping accommodation, and various other amenities of her career. These conditions are not constant and invariable in all the different classes of hospital; life in a children's hospital, a fever hospital, or a mental hospital has its special features. Making allowances for these differences, wide divergencies in many matters are found to exist. This Second Interim Report does no more than marshal facts and (on its last two pages) mention some opinions. The Final Report, expected to appear later in the year, will endeavour to recommend the remedies. Meanwhile, all who are concerned or interested in hospital nursing have the opportunity to give serious study to the materials which our supplement contains.

ECONOMO ON ENCEPHALITIS LETHARGICA.

IN 1917 Constantin v. Economo published a monograph entitled "Encephalitis Lethargica" in which he embodied the results of his researches on that disease. Twelve years later he gave an account of his further experience and surveyed the whole position. It is this latter work which Dr. Newman has now adapted to the needs of English readers.[1] Economo devotes some space to an assertion of his claim to have first identified and described encephalitis lethargica, "a new, hitherto unknown epidemic infectious disease, *sui generis*." This priority and the author's brilliant work is so universally acknowledged by neurologists as to make the assertion superfluous. When the disease was described, more or less independently, in 1918, by Cruchet and Netter in France and in England by MacNalty, McIntosh, and Marinesco, Buzzard and Wilson, due credit was given to Economo's prior claims, as soon as his original account[2] came through the war zone. At the same time Economo agrees with Crookshank and other medical historians that encephalitis lethargica has occurred before, although only now recognised as a pathological entity. He identifies with it the nona epidemic of the years 1890–91 in Italy, the "Tübingen sleeping sickness" of 1712, and various outbreaks of epidemic somnolence described by Ozanam, Lepecq de la Clôture, and others. This history is encouraging, for it strengthens the hope arising from the diminished incidence observed in most countries that the disease is disappearing from our midst. It is a fell disease, not only because of its high mortality in the acute stage, but on account of its severe after-effects. To these, under the title of "chronic post-encephalitic diseases," Economo devotes special attention, giving a concise account of the therapy both medicinal and psychological which his experience has shown to be useful. Dealing with the epidemiology and the character of the infection Economo considers it probable that the virus settles first in the naso-pharyngeal cavity and thence spreads along the lymphatic channels into the nervous system. It is therefore a droplet infection. He states that transmission of the disease from person to person seems rare and presumes this to be of secondary importance, because the virus once settled within the skull has little chance of getting out (*virus en cage* as Netter puts it). Here he seems to us to have paid rather scant attention to the possibility of carrier infection. In this respect encephalitis lethargica seems to follow the epidemiological behaviour of two other epidemic diseases of the nervous system, cerebro-spinal fever and poliomyelitis, in which contact infection plays a major part, but frequently escapes clinical notice because transmission is by the healthy carrier. Economo agrees with the view that the encephalitis of influenza is quite distinct from encephalitis lethargica. His book contains an excellent account of the acute forms of the malady, their course and prognosis, and of the morbid anatomy of both acute and chronic forms. A pleasing feature is the generous tribute paid by the author to the work of British investigators and to the report (1918) of the Local Government Board. Economo concludes his book with the remark: "Encephalitis lethargica can scarcely again be forgotten." Even if the time should happily come when the disease can only be studied in books such as this, Economo's fundamental discoveries will continue to influence the study of neuropsychology.

ACCESS TO MUNICIPAL HOSPITALS IN BIRMINGHAM.

THE Birmingham City Council has confirmed its decision to exclude general practitioners from the treatment of patients in its two municipal maternity homes. There was a time when the patients might be attended by their own doctors if they wished, but most of the deliveries were undertaken by midwives and, when help was needed, the local practitioners were summoned by the matrons. Difficulties however seem to have arisen in maintaining a uniform standard of efficiency and in obtaining the doctors just when they were wanted. About a year ago the Council came to the conclusion that the employment of whole-time officers would avoid embarrassments, ensure better care, and minimise the risk of infection, as well as providing staff for the antenatal wards, premature babies' wards, and child welfare clinics. It would also enable the pupil-midwives to receive uniform instruction and supervision and would ensure that the medical officer who had watched the antenatal period should have charge of the confinement. The work of private practitioners was to be safeguarded by imposing an income limit for patients admitted to the homes.

The Council was so convinced of the value of these advantages that, although the practitioners protested, it would not consider reverting to the old method. It was prepared however to consider an arrangement whereby a doctor might send his private patient into one of the homes and follow the case through. In collaboration with the local division of the British Medical Association, the Council tried to work out a scheme. The Association made it clear that Birmingham practitioners wished ultimately to follow their own patients into all the hospitals of the city, and set out a series of proposals for the management of the maternity homes. They suggested that each home should be run by a committee of six, three appointed by the municipal authority—one of them in executive control of the home—and three being general practitioners, the chairman being an obstetrician. Every practitioner living within two miles of the home should be asked whether he was willing to attend his own patients and emergencies in the home, subject to the rules and regulations of the committee, and those signifying assent should form a rota. This would ensure that every patient had an approved doctor and—subject to his being willing and available—the doctor of her choice. The Council however found itself unable to agree to this proposal on the grounds that it could not forgo direct responsibility for the management of its institutions; that the executive medical officer would be in an anomalous position, being only one of a committee of control; and that the variations in standard and the difficulty in securing prompt attendance would not be removed. There the matter rests. The practitioners uphold their claim to access, maintaining that the standard of work would be as high as could be obtained by other means. The Council disagrees and has intimated that it sees no advantage in continuing the discussion.

TUBERCULOSIS IN RUSSIAN INFANTS.

DR. E. Rautenstein, who is in charge of a welfare centre in Leningrad, has studied[1] seven babies who showed symptoms of tuberculosis before completing the third month of life. Out of a total of 213 infants under observation by her at the centre, twelve gave a positive tuberculin reaction and among these were the seven infants with clinical evidence in addition to the biological reaction. Dr. Rautenstein first discusses whether infection took place before or after birth. She concludes that intra-uterine infection is of more importance than is usually admitted, particularly if the view of Calmette and his collaborators as to the existence of a filtrable virus is accepted. At the same time it has to be remembered that so-called intra-partum infection cannot be altogether excluded and a strong case against postnatal infection can be made out if the liver is more severely affected than the lungs. In the cases described a decision was impossible because the isolation of the mother from the child directly after birth had not been carried out. In the first rank of clinical evidence comes the temperature chart; it was sometimes possible to trace a short initial fever, then a nearly afebrile period during which the tuberculin test became positive, and a terminal febrile phase. This sequence was not always seen because of the circumstances under which the infants were observed. At the earliest stage a frequent occurrence was a period of vomiting and loose stools due, in the author's opinion, not to local bacillary invasion of the alimentary tract, but to a general reaction of the body to its first dose of tubercle toxin. Physical examination of the lungs revealed, as a rule, evidence of infiltrated areas by alteration in the percussion note, the breath sounds being commonly diminished. Cough was absent until shortly before death except when there was pressure of enlarged mediastinal glands upon the trachea or main bronchi; then it had the characteristic "ringing" timbre. Hæmoglobin and red cells were diminished in all cases; a definite lymphocytosis was only present in cases which recovered. The sedimentation rate was higher in the fatal cases but the rate required checking by the lymphocyte count and the tuberculin test; with consistent positive test and high count, a rate above normal was not inconsistent with recovery. Liver and spleen were enlarged in all the seven cases. Dr. Rautenstein doubts whether tuberculosis is really becoming more frequent in the early months of life. Slow loss of weight, slight fever, and anæmia following a short bout of diarrhœa and vomiting lead to a diagnosis of "marasmus" which is rudely upset at the autopsy by the discovery of tuberculosis. Such errors, which are unfortunate in leading to the source of infection being overlooked, could, she thinks, be largely avoided by systematic radiological examination of the chest. Even at this early age the disease is not necessarily fatal; three cases in her series appeared to make a good recovery.

DIABETES MELLITUS IN THE UNITED STATES.

A RECENT analysis of the apparent increase in the death-rate from diabetes mellitus in the United States has brought to light some noteworthy facts.[1] The increase is not at all uniform, it seems, when analysed by age, sex, or race. Mortality among older women, especially among coloured women, shows a rise which more than outweighs the great and definite improvement among the young. In the years preceding the discovery of insulin the death-rate from diabetes was steadily increasing at all ages under 45; since 1922 there has been a sharp decline at those ages. Among males above this age the rate has remained fairly steady during the insulin period, but among females it has been stationary only between the ages of 45 and 55, and above this there has been a steady rise. Over 65, the mortality has increased among males by 25 per cent. and among females by 40 per cent., and if we take the last four-year period the increase has been 33 per cent. and 50 per cent. respectively. Among negroes there has been no improvement whatever. The death-rate for males under 45 has been stationary, while for females it has increased 60 per cent. Over 45, the male negro death-rate has gone up by 20 per cent. and the female by 75 per cent.

Unfortunately, it is not clear from the analysis whether diabetes was the primary or merely a contributory cause of death, and it may be that the increase in the older classes is due to improved diagnosis, and that the deaths were due to such causes as arterio-sclerosis, which, as Prof. D. M. Lyon and Dr. Murray Lyon[2] have pointed out, is as likely to be a cause of diabetes as a result of it. These authors showed that in deaths from coma the average age in 150 cases was 37 years, while in "non-coma" cases it was 62. It is difficult, however, to see why improved diagnosis should apply to women more than men, and to coloured women more than white, and the figures strongly suggest that on the whole the incidence of diabetes has risen and that insulin does not deal effectively with the "degenerative" type of diabetes in elderly people, where this disease is only a small part of the picture.

Another interesting contribution is a study of 300 diabetic ex-Service men undertaken by the Medical Service of the United States Veterans Bureau.[3] While no special tendency to diabetes, or modification of its effects as the result of warfare, seems to have been proved, the investigation confirms many of the points which have emerged from the study of the disease among the general population. For example, it was found that cases with a normal cholesterol content of the blood were more amenable to treatment than those in which it was high. The chief cause of the persistence of hyperglycæmia and glucosuria, in spite of insulin therapy, seemed to be the presence of complications or co-existing diseases —79 per cent. presented such complications, and the average number was 2·6 per patient. The mortality was 4·6 per cent., and in the 14 fatal cases five of the patients were over 45 years old. The principal cause of death in these five cases was stated to be diabetes mellitus in two, diabetic gangrene in two, and pulmonary tuberculosis in one; while the secondary causes were all arterio-sclerosis or its variants. Of the nine deaths under the age of 45, diabetic coma was the principal cause in four, pulmonary tuberculosis in four, and nephritis and myocarditis in one. An instructive feature of the series was that in only five out of 300 cases (1·7 per cent.) did the clinical symptoms in themselves denote the presence of diabetes, whilst 30 cases (10 per cent.) were entirely symptomless. This is exactly the figure given by Joslin, and shows once again the importance of routine examination of the urine.

METROPOLITAN WATER.

Sir Alexander Houston's[1] report on the chemical and bacteriological examination of the London waters deals with the 12 months ended Dec. 31st, 1930, and the Director of Water Examinations to the Metropolitan Water Board for the twenty-fifth time supplies a valuable scientific year book in a fascinating way, incorporating into statistical and laboratory statements and memoranda much apt and amusing anecdote.

The report commences by a description of the chlorination of the Thames and New River water, and as chlorination will, at any rate, until something preferable for bactericidal purposes be found, be an accepted process of purification, it is useful to read the arguments in its favour. The change of front on the part of the public, from hostility to tolerance, and from tolerance to appreciation, is marked, and Sir Alexander holds that this revolution of opinion has followed the publication of definite information on the subject no less than the technical improvements in method. The public has learned that chlorination is a cheap and harmless way of destroying the known germs of epidemic water-borne disease, while the great objection to the process, the taste, which was, when chlorination was first introduced, a very definite one, has been met successfully. The water-consumer has a right to demand a water which is not only safe, but which is inoffensive to the taste, and this position has been reached. But much careful experiment and assiduous trial has preceded this satisfactory result, the production of a tasteless as well as a safe water having considerably tested the resources of chemical research; and Sir Alexander may be legitimately proud of the ability to state that now in 999 out of 1000 supplies success has been achieved. But he is not unduly complacent, for he asks his readers not to regard chlorination, however carefully and efficiently practised, as the ultimate solution of all water problems. "We must still," he says, "seek virgin sources of water-supply, still retain and maintain, as far as this is reasonably practicable, the old-established armoury of defence." Chlorination, that is, should be regarded primarily as a means of amplifying security, to whatever extent it has already been secured.

Following the information on chlorination, we have a section on prefiltration waters, which is introduced by Sir Alexander with a paragraph in which he likens the 49 storage reservoirs, extending over 2700 acres and holding about 20,000 million gallons, to a great lake, and he finds that the feeling of safety engendered by the comparison of these reservoirs to a natural lake is not misplaced. In 1922 the examination of prefiltration waters, partly suspended in the period following the war, was reconsidered by the Board, when it was determined to examine completely and thoroughly, chemically and bacteriologically, and each week, all the various kinds of water which feed the filters, raw water, stored water, gravel water, and so on. There were certain difficulties incurred in the bacteriological examination, but the disadvantages were compensated for in other directions, and the bacterial and chemical figures, as summarised under bacteriological and chemical results, of raw river and prefiltration waters make remarkable reading.

We have next an interesting description of the search for pathogenic microbes in crude sewage, for which examples were collected at the Barking outfall hourly for 24 hours, and mixed proportionately to flow. The procedure in searching for the typhoid bacillus is set out at length, with close analysis and tabular statements. The relation between water-supply, the composition of sewage, and the meteorological conditions is recognised in a section comprising meteorological notes extracted for the most part from the *Meteorological Magazine*. A comment on the position in this country for the year 1930, contained in a communication made to the *Times* of Jan. 28th, 1931, by Mr. E. G. Bilham, is quoted as follows: "Decade for decade, year for year, and month for month, the ten years from 1921 to 1930, and the year 1930 itself, have, in the amount and persistence of the rainfall, surpassed most of the records of nearly all the corresponding periods since 1731. In the last 200 years only one previous decade—that of 1871–1880—has had a higher mean rainfall than that which has lately come to a close, with a correspondingly damp December." Sir Alexander must be one of the few people who can derive pleasure from such a statement; and his comment is to "hope that the amplitude of our sources of water-supply are not likely to be imperilled." The report closes with a description at some length of the Kempton Park Works, which, as the most up to date of all the Board's works, deserve this special notice.

GASTRITIS SIMULATING PYLORIC ULCER.

A STUDY of affections of the pylorus simulating ulceration has lately been published by Dr. Östen Holsti[1] of Helsingfors. It was prompted, he says, by two cases of severe dyspepsia treated in hospital in 1928 and 1929, in which operation was performed on account of suspected ulceration. No ulcer was found, either in the resected or in the remaining parts of the stomach and duodenum, but the microscope showed acute deep gastritis. Holsti has since carried out detailed microscopical and other examinations in similar cases, and the material he now presents consists of 14 patients, of whom only three were women. There was a history of chronic constipation in six cases, and the dyspeptic symptoms had often begun in early youth, and had lasted several years. In as many as 11 cases they were those of an uncomplicated, juxta-pyloric lesion. The Wassermann reaction in the blood was always negative. There was a history in many cases of temporary improvement following dietetic treatment based on the diagnosis of ulceration. When these patients came to operation, no ulcer of the pylorus could be found, but microscopical examination showed signs of endo-, myo-, and peri-gastritis. The two main seats of the inflammatory process were the mucosa propria and the plexus myogastricus. In half the cases, permanent relief from all the symptoms followed the resection. Of the remaining seven, two derived only temporary improvement from it, two did not even experience temporary improvement, and three could not subsequently be traced. Holsti concludes that his material represents a somewhat heterogeneous group, in the members of which there was an interplay of various factors of no uniform character. No case was so simple or early that only a single factor could be held responsible for all the morbid changes, and it would seem, he says, that a vicious circle is constituted by the inflammatory factor, disease of the arteries, venous stasis, and changes in the intra-mural plexuses—all or some of which are to be found in various degrees and combinations in each case.

PHYSICAL CONCOMITANTS OF MENTAL DISEASE.

THE research laboratories of the City and University of Birmingham have become associated particularly with the discovery of focal sepsis in cases of mental disease. The latest report, covering the twelve months ended March 14th, records a continuation of this work; in one murder-suicide case the sphenoidal sinus was found full of glairy muco-pus, and in a case of insanity following typical encephalitis lethargica the sphenoidal sinus showed marked chronic disease and contained pus. No less than 5367 specimens have been examined and reported upon by the laboratory, a work which has necessitated the manufacture and use of 42,500 tubes of media and 5470 plates of culture media, an average of 3500 tubes and 456 plates per month. Research into nasal sinus bacteriology accounts for the greater part of these. A new method of examining fæces for typhoid and dysentery organisms, by intraperitoneal injections of specially prepared material into mice, is being studied, and further work on agglutination tests has been carried out. As a result of a large series of experiments a method of demonstrating blood in brain vessels has been devised which is superior to the best injection methods and does not possess their insuperable difficulties. This method opens up a new field of research in cerebral localisation. By applying it to sections one quarter of a millimetre thick it is possible to examine a whole brain in a couple of months. Chemical experiments have been continued on the resistance of red blood corpuscles to hæmolytic agents under varying conditions, and the permeability of the corpuscular envelope to inorganic substances and dyes has been quantitatively investigated. The permeability of colloid albuminous substances without lipoidal envelope has been determined by the use of masses of raw egg-white. An attempt is being made to separate viruses from brain-mash obtained post mortem by cataphoresis, using hæmoglobin as an indicator. A series of experiments has been undertaken to show whether heat alone is responsible for the temporary increase in the permeability of the brain membranes which is known to occur during malarial treatment of general paralysis; results so far seem to indicate that it is.

THE WORLD'S REQUIREMENTS OF NARCOTIC DRUGS.

SINCE the production and distribution of opium, morphine, heroin, and cocaine assumed international importance under the Opium Convention signed at The Hague in 1912, various estimates have been propounded as to the amounts of these drugs required for legitimate medical purposes. The Health Section of the League of Nations a few years ago arrived at the conclusion that 10·4 tons of morphine, 0·87 tons of heroin, and 6·0 tons of cocaine might be held to represent the world's annual requirements. A laborious and elaborate analysis, recently completed by the secretariat of the League and based on the statistical returns from the various manufacturing and consuming countries has resulted in yielding uniformly lower figures than those vouchsafed by the Health Section. The secretariat's figures are 8½ tons of morphine "as such," about half a ton of heroin, and 5 tons, or rather less, of cocaine. The figure for morphine is given for "morphine as such" because there is also to be brought into account the morphine used for conversion into codeine, morphine esters, and ethers, which have not hitherto been classed as "dangerous drugs," as well as into dionin and apomorphine. If morphine so utilised is to be included the secretariat puts the annual requirement at 31½ tons for all purposes, although the actual manufacture of morphine in 1929 amounted to 59½ tons, and it is estimated that not less than 100 tons of morphine in all its forms passed into illicit traffic. As regards raw opium the League's secretariat gives 375 tons as the annual world requirement for legitimate purposes; there is, however, also the opium prepared for smoking, of which some 600 tons are annually exported, for which India is responsible to the extent of 66 per cent. Lastly there is the opium consumed in British India, which amounts to 200 or 250 tons a year.

THE HISTORY OF THE AMPUTATING KNIFE.

THE historical section of the Museum of the Royal College of Surgeons has received many additional possessions during the past twelve months, some of which are described in the annual report of the Museum. Of these, not the least interesting to surgeons and students are the specimens illustrating the history of the amputating knife, which show the many changes that the blade of this instrument has undergone during the past thousand years. The series, arranged chronologically, begins appropriately with a replica of a Roman scalpel or cutting knife that was found with other surgical instruments at Pompeii; for the first description of the amputation of a limb is that given by Celsus (A.D. 30). This is followed by the model of an amputating knife described by Albucasis, with a long straight blade terminating in a sharp point, called by him a "knife-rasor," which was employed in the tenth century. Next is a model made from a drawing in the manuscript work on "Chirurgery," written by John Wryghtson, an English surgeon, in 1350. The blade of this instrument is short and at the extremity is curved slightly inwards. A century later, as shown in the next specimen, the form of the blade was completely changed and is curved backward with the cutting edge on the outside instead of the inside of the curve. In 1578, Ambroise Paré, in his "Chirurgie," described two knives that he used when amputating, one of which he calls an incision knife and the other a "crooked knife for dismembering," the blade of which is crescent-shaped with the cutting edge on the inside. The amputating knife described by another famous French surgeon, Guillemeau, in 1594, has a broad blade curved only at the extremity and is similar in shape to Wryghtson's knife of the fourteenth century. The knife described by Fabricius Hildanus in 1646, of which a model is shown, differs widely from its predecessors. It has a heavy blade shaped like a scimitar with the cutting edge on the outside of the curve. But this innovation apparently did not last long, for in 1665 Scultetus describes the amputating knives used in his time as having a crescent-shaped blade and figures a "crooked knife, wherewith," he says, "the flesh is to be cut in so far as the bone which must be saw'd off."

Early in the eighteenth century Sharp introduced his amputating knife with a curved blade which was sometimes made with a double edge, and later Perret's still more crescent-shaped blade with a periosteal elevator came into use in France about 1772. From 1760 to 1775 the curved blade of varying shape was favoured and it was in general use until 1788, when Loder advocated a knife with an almost straight blade which he had found to be effective. From about this period, the straight-bladed and relatively small amputating knife began to replace the strongly curved instruments used by Sharp and other surgeons in the earlier part of the eighteenth century. Benjamin Bell figures a straight knife in his "System of Surgery" in 1788, and Savigny in 1798 illustrates a knife with a blade intermediate between Bell's and Perret's, which shows that the straight type was gaining in favour. Savigny points out that "care should be taken in the construction of this instrument that the back is not thicker than is absolutely necessary to give and support the required firmness of the edge, otherwise it becomes unwieldy in its management." Sir Astley Cooper, however, appears to have preferred the broad back, for his amputating knife, shown in the series, has a very thick back with the sides of the blade much smoothed along its borders, but the blade is straight. Lisfranc, who observed that he preferred straight knives for amputation, taught that "when a knife is required for the forearm or leg, the cutting edges should be extended to the insertion of the blade into the handle." He therefore had his knives made with long slender blades with double edges. In 1846 Robert Liston established the long straight blade in favour, and this type has remained almost unchanged. His knives, which he had made in various sizes, sometimes measured over a foot long in the blade alone and were finished with a dagger point, the backs being sharpened for the last two inches. The cutting edge was almost straight till it curved upward near the free end to meet the back. In his "Practical Surgery" he thus explains his reason for the long slender blade: "The form and size of the instrument ought always to be in proportion to the extent of the proposed incisions as regards both their length and depth. If an extensive incision is necessary, an instrument presenting sufficient length of edge must be employed so that the parts may be separated smoothly and quickly." Although his knives had wooden handles, Liston always insisted that the handle of a surgical knife should be perfectly smooth and polished, so it could be effectively cleansed, and this idea was adopted by Lister.

This series serves to illustrate the interesting fact that in re-establishing the advantage of the long straight blade, Liston was but reviving a type that had been used by the Arabian surgeons of the tenth century.

INDEX TO "THE LANCET,"

VOL. I., 1931.

THE Index and Title-page to Vol. I., 1931, which was completed with the issue of June 27th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

SPECIAL ARTICLES

A NATIONAL MATERNITY SERVICE.

ANALYSIS OF FOUR SCHEMES.

Prof. J. M. Munro Kerr, at the forty-second Congress of the Royal Sanitary Institution held at Glasgow from July 4th to 11th, set out a scheme for a national maternity service. This differs in many respects from those already outlined in the Interim Report of the Departmental Committee on Maternal Mortality and Morbidity, published in August, 1930, and from the British Medical Association's Memorandum on a National Maternity Service Scheme for England and Wales, published in June, 1929; but it has a number of points in common with that described by Prof. W. Blair Bell in our issue of June 13th last.

GENERAL OUTLINE OF THE SCHEMES.

The need for more systematic and better antenatal and postnatal care is admitted by all. Prof. Blair Bell declares that the people who know most are not always in charge, and urges a scheme to pool resources.

The essential elements of the schemes of the Departmental Committee and the B.M.A. are the provision of a trained midwife to be responsible for the conduct of pregnancy, labour, and the puerperium; to supervise the patient, to teach her hygiene, and to call in the doctor for any abnormality or difficulty. Every patient at the same time is to be in touch with the doctor of her choice, who will make at least one statutory antenatal and one postnatal examination, and attend as required. The antenatal clinics in both these schemes would become more and more consultative or educational, and would only exist as routine centres where the doctor preferred to make his antenatal examinations at a clinic rather than his own consulting-room.

Prof. Munro Kerr starts from the same premise as the others—that the normal midwifery of the country is passing, and will continue to pass, into the hands of midwives, and that general practitioners for the most part do not wish to retain it. Those of them who are specially interested, and can spare the time, will be included in his obstetric service.

While the schemes of the Departmental Committee and the B.M.A. start, as it were, from the periphery—concentrating on the individual patient—those of Prof. Blair Bell and Prof. Munro Kerr work outwards from the centre, concentrating rather on the institutions that are to form the nuclei of the service.

ACCESSORY SERVICES.

The reports of the Departmental Committee and of the B.M.A. discuss the subject under the headings: doctor, midwife, accessory services. The doctor and the midwife are to perform the services already described, and both reports urge the need for better education in medical schools and midwives' training schools. Both suggest that an anæsthetist should be available under the scheme when required, but neither proposes the provision of anæsthesia for normal cases—a probable demand of parturient women in the future. Both provide for consultant services when the doctor in charge needs them, and both allow for institutional care of abnormal cases and of normal cases at the patient's wish or when home conditions are bad. Prof. Munro Kerr would have every primipara delivered in an institution. Both the Department Committee and the B.M.A. hope that the general practitioner will be able to follow his cases through their institutional period, but the Departmental Committee suggests that some one person—perhaps one general practitioner in a district—shall be appointed in charge of the institution, to give unified control and maintain the standard of treatment.

The B.M.A. wishes sterilised outfits to be provided in every case; the Departmental Committee would only have them "where required." The B.M.A. provides for home helps, and the Committee regards them as desirable. The other two schemes do not deal very much with these points. Prof. Blair Bell would have anæsthetics available everywhere, and would provide home helps. He would, however, make a radical change in the midwife system, insisting that all nurses who undertake obstetric work should be fully trained and should live in hostels, whence they would work both the clinics and the midwifery service.

THREE TYPES OF HOSPITAL.

Prof. Munro Kerr and Prof. Blair Bell both propose a regional scheme based on three types of hospital; Prof. Blair Bell compares his types to the base hospital, the field hospital, and the casualty clearing-station, familiar to us in the war. With these correspond fairly closely Prof. Munro Kerr's primary, secondary, and subsidiary institutions.

The "Primary" or "Base" Hospital.—Prof. Blair Bell would have areas of approximately 50 miles round a teaching hospital. At this base hospital he would have both students and midwives taught, and general, consultant, and specialist services provided for the area. He stresses the importance of having this in a general hospital, partly for reasons of economy, partly to ensure a better sense of proportion, and partly because of the better nursing service and the readily available consultative service in all departments. He would build no new maternity hospitals, but would build on to existing general hospitals where more accommodation was necessary. He would have these centres coöperate with existing maternity hospitals.

Here Prof. Munro Kerr differs from him, for he would have his primary hospital at an existing obstetric hospital. The teaching in these units would be primarily for medical students and not for midwives, and stress should be laid on post-graduate courses. The work would be general, consultative, and investigatory, with a domiciliary service, but not postnatal or infant welfare. He agrees with Prof. Blair Bell that the unit should be in charge of a university professor, so that there could be coöperation with the university laboratory and staff. He would do gynæcology in these primary units, but lays less stress on it than Prof. Blair Bell does in his base hospital, and would do especially emergency work, the primary centre being connected with the surrounding area by an efficient motor ambulance service. These should also be the research centres, equipped with first-class laboratories.

The "Secondary" or "Field" Hospital.—The second class of hospital in Prof. Munro Kerr's scheme would be of three types:—

(a) Other hospitals in cities where a "primary" is situated; these should be autonomous with full status, but they should not take the most difficult or the emergency cases, but should be reserved for "clean" cases and do the ordinary

NATIONAL MATERNITY SERVICE: COMPARISON OF THE FOUR SCHEMES.

—	DEPARTMENTAL COMMITTEE.	B.M.A.	BLAIR BELL.	MUNRO KERR.
Principal idea of scheme.	Provision of midwife for every case, and doctor for ante- and postnatal care and abnormality.	Same as Deptl. Ctee.	Definite National service to pool resources and give control to obstetricians.	Network of obstetric centres on basis of existing organisations.
Duty of doctor.	Responsible from "booking" to end of puerperium; specified antenatal and postnatal examinations. Attendance as required by midwife.	One prescribed antenatal and one postnatal examination and see patient when referred by midwife.	General practitioners or pædiatrists would staff clinics remote from the hospitals and some of the clinics at large hospitals ("field").	General practitioners would staff cottage hospitals and the antenatal, postnatal, and infant welfare clinics run from them. Panel of G.P.'s specially interested.
Duty of midwife.	To supervise; teach hygiene; arrange antenatal care; attend labour and puerperium (14 days); advise postnatal examination; refer to doctor for any abnormality. Standard of midwife to be raised.	Same as Deptl. Ctee. To have more practical training.	Midwives to be abolished and all obstetric nurses fully certificated, living in hostels and working the clinic and domiciliary service from them.	—
Duty of clinics.	To become more and more consultative and to teach midwives.	To teach mothercraft. If doctor prefers to see his patient in a clinic, then a clinic should be arranged for him at the local maternity hospital.	Those at "base" to be consultative.	To become sorting-out centres, keep records, do simple laboratory tests, and arrange supplementary services and domiciliary work.
Domiciliary services.	Average case to be attended at home. Home helps desirable.	Normal cases treated at home. Home helps to be available.	To be run from "field" hospitals, worse cases being referred to base. Home helps.	To be run from all three types of hospital by G.P.'s specially interested and prepared to undertake whole care. Home helps.
Delivery in hospital.	Beds for abnormal cases; when the home conditions are bad or when the patient wishes. G.P. to follow case through.	Beds where required (as in Deptl. Ctee). Same doctor to attend if possible. Three per cent. need hospital treatment; 1500 beds required.	One quarter of cottage hospital beds (not less than three) should be maternity.	All primiparæ to be delivered in an institution, in addition to those recommended by Deptl. Ctee.
Anæsthesia.	Anæsthetist to be provided for abnormal cases free; at a fixed fee for normal cases.	Anæsthetist to be available when needed.	Available everywhere.	—
Consultant.	To be available when required.	Same as Deptl. Ctee.	Bad cases sent to "field" or "base" hospital.	Bad cases to be sent to primary or secondary centres by motor-ambulance.
Sterilised outfit.	To be provided when needed.	To be provided in every case.	—	—
Central organisation.	Scheme to be worked by existing doctors and midwives—with better education.	Same as Deptl. Ctee.	General directing ad hoc body representative of all concerned. Independent chairman. Reports direct to Minister of Health.	General directing ad hoc body with powers to train and discipline midwives. Representative of all concerned. Chairman: chief medical officer of district.

THREE TYPES OF HOSPITAL:

BLAIR BELL.

Base. Field. Casualty clearing.

BASE HOSPITAL.

At an existing general hospital in a university centre. Run by professor, coöperating with colleagues in university laboratories and at hospital. To be general, consultative, and specialist. To teach students and midwives. To have maternity and gynæcological beds. To cover area of 50 miles radius. Consultative antenatal, postnatal, and infant welfare clinics and beds.

FIELD HOSPITAL.

Large general hospital with maternity ward, clinical laboratory, and isolation block. To do antenatal, postnatal, infant welfare, and domiciliary work, in- and out-patients. To work in its immediate district, referring the worst cases to the base. Specialists, junior obstetricians, and general practitioners on the staff.

CASUALTY CLEARING STATIONS.

Cottage and small hospitals, one-quarter of their beds being for maternity. Liaison with base. Antenatal and postnatal beds.

NETWORK OF CLINICS.

(a) At base, run by experts, consultative.
(b) Scattered round base, associated with it, and run by junior experts and general practitioners.
(c) More remote, connected with field hospital or casualty clearing station, and run by general practitioners and pædiatrists.

MUNRO KERR.

Primary. Secondary. Subsidiary.

PRIMARY HOSPITAL.

At an existing maternity hospital in a university centre. Run by a professor, coöperating with colleagues in university laboratories. Senior staff allowed to do private practice. Staff resident as far as possible. To do normal cases and particularly emergency cases, and to be consultative and investigatory. To teach post-graduate students only. No postnatal or infant welfare work. Gynæcological beds and clinic, if possible. Antenatal clinic and beds.

SECONDARY HOSPITALS.

(a) Other hospitals in city where there is a primary. Independent, with full status, but not to take most difficult cases or emergencies. Teach midwives primarily. Do gynæcology, antenatal, postnatal, infant welfare, and domiciliary work. Staff similar to primary, but simpler.

(b) Towns with no primary centre. Hospital does ordinary obstetric work—antenatal, postnatal, and domiciliary—and simple gynæcology and laboratory work. In liaison with nearest primary by motor-ambulance.

(c) Cottage hospitals, staffed by general practitioners. Direct the antenatal, postnatal, and infant welfare work of district, and have beds for emergencies and antenatal cases.

SUBSIDIARY.

Antenatal, postnatal, and infant welfare clinics, and a domiciliary service under the local health authority. Each clinic associated with a particular secondary or primary. Run by general practitioners, public health officers, and pædiatrists.

work of an obstetric hospital. They would teach students and midwives, but their teaching would be primarily for midwives. They would hold antenatal, postnatal, and infant welfare clinics and have ante- and postnatal beds, and run a domiciliary service. They would also do gynæcology.

(*b*) Hospitals in towns or small cities where there was no primary centre. These would do ordinary obstetric work, provide antenatal and postnatal beds and clinics, simple gynæcology, simple laboratory work, and a domiciliary service. Their antenatal clinics would be consultative for the subsidiary centres.

(*c*) The cottage hospital would deal with emergencies and have antenatal beds, and direct the antenatal, postnatal, and infant welfare work of the area.

The first and second class would be staffed similarly to the primary hospital, but more simply, and the third class would be staffed by general practitioners.

Of these the second group corresponds fairly closely to Prof. Blair Bell's field hospitals, which would be large general hospitals containing maternity and isolation wards and a clinical laboratory, and carrying on antenatal, postnatal, infant welfare, and domiciliary services. They would be built on a standard plan adapted to local needs, and would work in their immediate districts, referring their worst cases to the base hospitals. They would be staffed by general practitioners and junior obstetricians.

Clinics and "Casualty Clearing Stations."—Finally, Prof. Munro Kerr would have a limited number of subsidiary centres in large towns or large rural areas. These would be antenatal, postnatal, and infant welfare clinics under the local authority, each associated with a particular primary or secondary unit. They would be the sorting-out and coördinating centres. They would have a secretarial department and a simple laboratory for urine testing. Records would be kept there and social services (home helps, accouchement outfits, &c.) would be arranged from them. The work would be done by general practitioners, public health doctors, and pædiatrists.

Prof. Blair Bell's "casualty clearing stations" correspond to (*c*) of Prof. Munro Kerr's secondary units—viz., the cottage hospitals. Prof. Blair Bell says that each of these should have one-quarter of their beds devoted to maternity, with a total of not less than three, and that they should run antenatal and postnatal work, referring difficult cases to the base hospital or getting help from there. He says that there should be one isolation centre in each district in the same town as the field hospital, in charge of the best obstetrician available. In addition, he would have a network of clinics, those at the base being consultative and run by experts, those scattered round the base being associated with it and run by junior experts and general practitioners, and those in remote districts being run by general practitioners or pædiatrists and being connected with a field hospital or a casualty clearing station.

Prof. Munro Kerr declares that it would not be satisfactory to have the clinics run by public health whole-time workers, and, although it might be tempting to have them run by the staff of an obstetric hospital, he feels that if this were once inaugurated the general practitioners would never get back again. On the whole, he thinks they should be run by practitioners, but he sees the disadvantage that practitioners in large cities would not be able to follow their institutional cases through a hospital.

THE DIRECTING BODY.

To run this scheme Prof. Munro Kerr would have a general directing ad hoc body with powers to train and discipline midwives. The body should be representative of all concerned—obstetricians, medical practitioners, medical officers of health, midwives, insurance commissioners, Ministry of Health, and local authority—and the chairman should be the chief medical officer of the Health Department. This corresponds fairly closely with the governing body suggested by Prof. Blair Bell, except that he would have the practitioners represented through the B.M.A., and the obstetricians through the College of Obstetricians, and would have an independent chairman. Prof. Blair Bell's great idea is to get the scheme under the control of the obstetricians, whereas Prof. Munro Kerr would associate it primarily with the Department of Health.

Prof. Munro Kerr's two great points are that obstetrics is a distinct entity, and, of all departments of medicine, the one most suited to have a service of its own, and that the present time is peculiarly opportune for inaugurating such a service, particularly on account of the Local Government Act, 1929.

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

LOTTERIES, APPEALS, AND TAXES FOR HOSPITALS.

ECONOMIC conditions are making the financing of the public hospitals in New South Wales particularly difficult. Almost all these institutions depend on large annual Government subsidies, which in the past have been granted on the basis of £1 for each £1 contributed by the public. Not only have voluntary contributions diminished considerably, but the State Government have found it impossible to continue its subsidies on the former scale. The £1 for £1 subsidy has been discontinued, and each hospital receives subsidies at the discretion of a Hospitals Commission. In spite of strict economy and exploitation of every possible source of revenue, a number of hospitals have had to close wards. Recently, the Royal Prince Alfred Hospital, the largest hospital in Sydney, closed 200 of its beds.

The efforts of the State department to meet this extraordinary position have been interesting. Betting has always been a favourite source of revenue for the hospitals, and a percentage of the gross proceeds of the totalisators, which are found on all large racecourses in New South Wales, has always been reserved for them. When funds from this source showed a falling off the deficiency was countered by fairly heavy taxation on all bets made through bookmakers. This however, did not appear to give the anticipated return, and the next step was to make a change in the method of betting on the totalisator. Now, not only is it possible to bet for a place, but there is also a special "straight out tote" in which winnings are divided among the ticket-holders of the first horse only. This has resulted in a considerable increase in the turnover of the totalisator, and thus, indirectly, in the amount available for distribution to the hospitals.

Seeing that large sums of money are contributed annually from New South Wales to a private Tasmanian lottery, and to a government lottery in Queensland, it was not surprising that the State parliament, early in the year, passed an Act for establishing a New South Wales State lottery in aid of hospitals. This was opposed very strenuously by the Council of Churches, a body composed of representatives from most of the Protestant churches in New South Wales. The Council recommended a Church and State appeal, to which the Council would give its utmost support. The Premier agreed to this, but, it is understood, intimated that if it were not successful a lottery would be instituted. The appeal failed hopelessly, and the State lottery will be launched at a very early date. Tickets will be 5*s.* 3*d.* each, the first prize being £5000, and it is proposed to hold one every ten to fourteen days. It is estimated that a fully subscribed lottery should bring gross receipts for about £26,000, and that it will result in additional revenue of about £400,000 a year.

The Hospitals Commission, in its annual report, suggests a further source of revenue in the form of a special tax on motor vehicles—this although the population is groaning under a burden of taxation which is probably without equal anywhere else in the world. The reason given for the suggested tax is that, as motor vehicles are responsible for an increasing number of accidents, they should be made to pay their contribution towards the hospitals, which deal with their victims. It is estimated that 5 per cent. of the gross total of hospital days, for which all general cases were in hospital, were the result of motor accidents—that is, about 100,000 bed days per annum. It is recommended that an addition of 5*s.* should be made to the registration fee for each motor car, which would give a revenue of £55,000 per annum. From this it is proposed to recoup public hospitals to the extent of 7*s.* per bed per day for all motor accident cases admitted, and 5*s.* for attention to similar cases to out-patients. Further, 6*d.* would be paid for every mile actually travelled by ambulance transport cars for the purpose of conveying injured persons from the scene of the accident to the nearest public hospital.

ROYAL AUSTRALASIAN COLLEGE OF SURGEONS.

Now that the prefix Royal has been added to the title of the College, the name of the College of Surgeons of Australasia has been changed to the Royal Australasian College of Surgeons, and the latters signifying the Fellowship from F.C.S.A. to F.R.A.C.S. The word "Australasian"—which is at best somewhat vague and unsatisfactory—has been placed in the middle of the name, to avoid confusion with the Royal Colleges of Great Britain. The journal has altered its name to the *Australian and New Zealand Journal of Surgery.*

Although the college has been in existence but a few years, there are now two honorary Fellows, 391 Fellows, and 17 junior members, and at the recent fourth annual meeting, held in Sydney, 30 new Fellows were elected. A revision of the policy of future admission of Fellows is under consideration; it is suggested that each candidate, after he has obtained a senior surgical degree and has served the necessary period of surgical apprenticeship, should be interviewed by a board of censors, which should satisfy itself as to his surgical training and ability. At present the college is trying to obtain some uniformity in the M.S. degrees in the universities of Sydney, Melbourne, and Adelaide, and its efforts have met with a certain measure of success. Each university has agreed to some modification of its regulations for this degree, but they are still far from uniform, and likely to remain so. Adelaide and Sydney have adopted regulations which are for the most part similar, requiring the candidate to pass the first examination in anatomy and physiology (and, in Sydney, pathology), and a second examination, in which he may select a number of groups of subjects. These groups are, roughly: general surgery, obstetrics and gynæcology, diseases of the eye, and diseases of the ear, nose, throat, and larynx. Melbourne, on the other hand, has refused to grant an M.S. degree in the various specialties, for which it is substituting diplomas. At the recent annual meeting of the college it was decided to ask the University of Sydney to pass a regulation to the effect that candidates who passed a Primary Fellowship examination of the Royal College of Surgeons of England, might be exempted from Part I. of the examination for the M.S. degree. Although Melbourne has agreed to do this, it is thought unlikely that Sydney will agree. It is obviously of great importance to the college to obtain a uniform surgical standard of examination, and a number of Fellows think that the only satisfactory solution is for the college itself to hold examinations.

It is likely that the permanent building for the college will be in Melbourne. At the first annual meeting, held at Canberra, a site was granted there by the Federal Government for the erection of a building. Canberra, however, is not altogether suitable, because it is so far from all the executive members.

THE PRIMARY FELLOWSHIP EXAMINATION.

The Primary Fellowship examination of the Royal College of Surgeons of England begins at Melbourne on Aug. 11th. The following examiners have been appointed: Prof. William Wright, anatomy; Prof. G. A. Buckmaster, physiology; Prof. F. Wood Jones, assessor in anatomy; and Prof. W. A. Osborne, assessor in physiology. Associate Prof. H. S. Summers is superintendent of the examination, and Dr. W. A. Hailes is superintendent of dissections. Although the total number of candidates is not definitely known, there will probably be at least between 20 and 30. The present economic condition of the country will however prevent a number from sitting.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

B C G STATISTICS UP TO DATE.

I SEEM always to be coming back to B C G, and by now, perhaps, some of your readers may wonder if your Paris correspondent has not got an *araignée dans le plafond* as far as this subject is concerned. But I am ready to wager all the gold you have sent us this last week or two that the historian of a century hence will say that the interest taken in B C G in France in 1931 surpassed the interest taken in all the other medical problems put together.

It will be remembered that an inquiry was addressed in January of this year to the tuberculosis dispensaries with experience of B C G vaccination in France. The answers from this source, together with other new statistical data, have now been collected by Calmette, who presented a report to the Academy of Medicine on July 21st. It deals with the period 1925–1930, and with the information obtained from 114 dispensaries, and from the medical practitioners and midwives of 42 departments. The first batch of figures, obtained from the 114 dispensaries, have been handled by Mr. Moine, the expert statistician, and they deal exclusively with the children born and brought up in tuberculous surroundings, and kept under the supervision of the dispensaries. Among the 8075 infants vaccinated, there were 89 who died within the first month of life and 581 who died (general mortality) in the course of the five years under review. There were 371 deaths among 2685 vaccinated infants between the ages of one month and one year, and 121 deaths among the 4811 vaccinated children between the ages of one and four years. Among the 579 vaccinated children over four years there were no deaths. The mortality of the vaccinated infants between the ages of one month and one year, born in tuberculous surroundings, was 4·7 per cent., whereas the general mortality of the non-vaccinated infants of the same age, living or not living in tuberculous surroundings, was 6·1 per cent. The mortality among the non-vaccinated infants, living in tuberculous surroundings, under the supervision of the dispensaries, ranged from 16 to 25 per cent. The information obtained from the 388 medical practitioners and midwives of 42 departments shows that 22,746 children have been vaccinated and kept under supervision. There were 174 deaths (a mortality of 0·7 per cent.) during the first month of life—i.e., before the vaccination could help in any way. There were also 408 deaths from all causes (a mortality of 1·8 per cent.) between the end of the first month and that of the fourth year. Commenting on these figures, Calmette described them as being more satisfactory than he had dared hope. He added that up to July 1st, 1931, some 354,000 children had been vaccinated with B C G in France alone.

FURTHER DATA ON B C G.

The first to give B C G to human beings were Dr. Weill-Hallé and Dr. Turpin, who, between 1921 and 1924 gave it by the mouth to 321 new-born infants. The subsequent careers of these juvenile pioneers of experimental medicine are, of course, of exceptional interest, not least to the physicians who took the risk of this particular step. In a communication to the Academy of Medicine on July 21st, Dr. Weill-Hallé presented a study of the comparative mortality among the infants given, or not given, B C G, in 182 families, which included 716 infants. The families were classified according as they were healthy, definitely tuberculous, or suspect. Within the first 12 months of life in healthy families there were 136 non-vaccinated infants with a mortality of 27 per cent., and 55 vaccinated infants with a mortality of 10 per cent. In the tuberculous families there were 175 non-vaccinated infants with a mortality of 29 per cent. (51 deaths within the first year of life), whereas among the 67 vaccinated infants the mortality was only 8·9 per cent. (six deaths). In the "suspect" families there were 215 non-vaccinated infants with a mortality of 37 per cent., and 68 vaccinated infants with a mortality of 16 per cent. Similar marked differences between the fates of the vaccinated and the non-vaccinated, in favour of the former, were found among the children over the age of one year.

THIRD INTERNATIONAL CONGRESS ON RADIOLOGY.

This Congress, held between July 26th and 31st, was attended by representatives from some 30 different countries. Madame Curie was elected honorary president, and the inaugural address was given by Prof. Forssel, of Stockholm, who chose as his subject the social campaign against cancer. The fact that more than 300 communications were addressed to the congress will give some idea of its importance. One of its tasks has been to pave the way towards international unification in radiology. To this end a commission has been appointed, on which the principal countries concerned are represented by experts in physics and medicine. An exhibition of the paraphernalia evolved from radiology was organised in the outskirts of Paris, at the Porte de Versailles, and it was amazing to see what a diversity of instruments and apparatus has grown out of this new science. Transportable devices figured prominently, and one of the most conspicuous was a large aeroplane provided with a special radiographic outfit to be used for the wounded who have fallen far afield, and for whom immediate transport is not feasible. The exhibition was open to the public free of charge, but one could not help wondering how this imposing array of highly technical specialties could do more than mystify and vaguely impress the ordinary sightseer.

MEDICINE AND THE LAW.

A Question of Age.

If an Act of Parliament refers to "a man of 23 years of age or under," do the words cover a man of 23½? The question has so puzzled the Court of Criminal Appeal that the number of judges had to be increased from three to five in order to obtain a solid decision; in the end the decision, though adequate, was not definite. The disputed words occur in the Criminal Law Amendment Act of 1922. A previous Act of 1885, dealing with the offence of carnal knowledge of a girl between 13 and 16 years of age, allowed an accused person to escape conviction if he could establish that he had reasonable cause to believe that the girl was of or above the age of 16 years. In 1922 this possible defence was abolished; in its place a different proviso was added—namely, that "in the case of a man of 23 years of age or under" the presence of reasonable cause to believe the girl to be over the age of 16 years should be a valid defence on the first occasion on which he was charged with this particular form of crime. This proviso to Section 2 of the Act of 1922 was an improvised piece of amateur draftsmanship. To speak of a girl as "of or above the age of 16 years" is perfectly clear; to speak of a man as "of 23 years of age or under" is ambiguous. A man charged with this offence at Huntingdon Assizes was found to have committed it in March, 1930. He was born on Sept. 26th, 1906, so he had passed his 23rd birthday on the day of the offence and had not yet reached his 24th. Mr. Justice Avory, at the trial, held that the accused was too old to avail himself of this statutory defence. The same ruling had been given in R. v. Dumont last year. In the Court of Criminal Appeal the appellant's counsel said a man was "of 23 years of age" until he reached 24. Counsel for the Crown argued that there were three categories—"under" 23, "of" 23, and "over" 23; all these were referable to a definite standard of time, the attainment of the 23rd birthday. The Court allowed the appeal on the broad principle that, when an equivocal word or ambiguous sentence leaves a doubt of its meaning which the canons of interpretation fail to solve, the benefit of the doubt should be given to the subject and against the Legislature, which has failed to explain itself. Even now, therefore, we do not know what the disputed words mean. We are merely told that they are so justifiably disputed that it would not be fair to use them to put anyone in prison. In effect, therefore, a "man of 23 years of age or under" means a man under 24.

The decision hardly seems one of those where fresh legislation is required in order that the law may be brought into line with what Parliament may be supposed to have intended. The reformers, in 1922, were disinclined to accept any proviso, but they were pressed with arguments that the law should not multiply the opportunities of blackmail. Parliament, it was said, should be slow to make a criminal of a young man who might be honestly misled as to a girl's age; in the matter of dress and the wearing of the hair, distinctions between the ages of 15 and 17 were nowadays negligible. In R. *v.* Dumont the girl was 15 years and 9 months old; she had told the defendant she was 19; the Recorder of London at the trial said she looked at least 17. In the 1922 Act the reformers' main object was to punish the offences of old men with young girls; from this point of view there is little difference between 23 and 24.

Cremation—the Medical Attendant's Certificate.

A rather insignificant printing error, in the form of the "Certificate of Medical Attendant" (Form B) in the Cremation Regulations, may have caused a disproportionate amount of trouble to the practitioner. The original Regulations, made in 1903, prescribed, in Form B, the following question and direction:—

> 9. What was the cause of death? { Primary.
> Secondary.
> (Specify the disease, injury, &c., and if possible distinguish the primary from the secondary cause as in the Death Certificate.)

In 1920 the Regulations were reissued without alteration to this passage. Six years later, the amending Births and Deaths Registration Act enacted that every certificate of cause of death required to be given by Section 20 of the 1874 Act should be "in the prescribed form"; the "Form of Medical Certificate of Cause of Death," subsequently prescribed in the Third Schedule to the Registration (Births, Stillbirths, Deaths, and Marriages) Consolidated Regulations, issued in 1927, speaks of "immediate cause," but omits all reference to the former classification of "primary" and "secondary." Last October new Cremation Regulations were made. The new Form B contains the old question 9 ("What was the cause of death?"), but adds thereto new requirements of information to conform with those on death certificates; the practitioner must now specify "immediate cause," "morbid conditions . . . giving rise to immediate cause," and "other morbid conditions (if important) contributing to death, but not related to immediate cause." But, though the old classification of "primary" and "secondary" has thus disappeared, by some oversight the words "primary" and "secondary" have been left in the form as they appeared on bracketed lines in the original Regulations of 1903. The unexplained retention of these two words must have puzzled many certifying practitioners, but need do so no longer. The Home Office, it is understood, is taking steps to delete the otiose words and to explain that they were printed in error.

PANEL AND CONTRACT PRACTICE

RANGE OF SERVICE.

SOME months ago, at a meeting of the insurance committee for the County of London, doubts were cast upon the competence of the committee, consisting as it does of a majority of lay members, to express an opinion on medical questions. The point specially concerns "range of service" cases; laymen must find it hard to decide a question whether an operation or other service advised for, or rendered to, a patient by a practitioner is within the scheme of the practitioner's obligations under the Terms of Service, or whether it involves special skill and experience such as general practitioners as a class cannot reasonably be expected to possess. Under Article 43 of the Medical Benefit Regulations a "range of service" question must be submitted to the local medical committee. If the local medical committee and the insurance committee disagree, the question must be submitted to referees; if they agree it may still be referred to referees by the Minister. In order to place these cases in the clearest possible way before the insurance committee within Article 43, the London medical benefit subcommittee now puts them forward with a definite recommendation that the insurance committee be invited either to agree or to disagree, as the case may be, with the local medical committee. Not only does this procedure comply more exactly with Article 43; it also helps to simplify for laymen, and possibly to limit, discussion of a medical matter.

We note that lately the London insurance committee was invited to disagree (and did disagree) with the local medical committee's opinion that the treatment of varicose veins by injection involved special skill and experience such as general practitioners cannot reasonably be expected to possess. The decision conforms with that of the referees in the Kent and Leicestershire cases mentioned in this column a fortnight ago. On the other hand, the insurance committee agreed with the local medical committee's opinion that the following were services requiring such special skill and experience and justifying the charging of a fee within Clause 10 of the Terms of Service: Refraction for myopia and for presbyopia, refraction under mydriatic for astigmatism and for hypermetropia, ultra-violet rays for neurasthenia, septic tonsils dissected out, and tonsillectomy. Another operation for which a fee was allowed was the incision of a swelling in the middle line of the neck. The patient had suffered from suppuration of one of the deep cervical glands of the anterior triangle of the neck; this necessitated a general anæsthetic and careful dissection in order to expose the gland, which was then incised and a rubber tube inserted. The two committees agreed that this required special skill and experience.

HEALTH INSURANCE IN SWEDEN.

The reform Bill rejected by the Riksdag in 1930 has now passed both legislative chambers. The system of health insurance set up by it will, however, not come into force until 1935, and as regards medical benefit not till 1938. The new powers make it possible to use sickness funds for purposes other than health and maternity insurance, and the National Labour Office says[1] that the measure is regarded in many quarters as a step towards compulsory health insurance. At present the principle of voluntary insurance is retained but an organisation is set up to prevent the overlapping of funds; the State subsidy is increased, and both sickness and maternity benefits are larger in cash and in kind. An order has been issued requiring insurance institutions to administer the payment of State relief intended primarily for women of small means who are not members of a recognised sickness fund. Uninsured women who cannot meet the expenses connected with their confinement are entitled to an allowance of one krona a day for thirty days, which can be increased to 56 days in the case of women employed in industrial undertakings.

CORRESPONDENCE

RETIREMENT OF DR. STEVENSON.

To the Editor of THE LANCET.

SIR,—We do not wish the retirement of Dr. T. H. C. Stevenson from his official work at the General Register Office to pass without an expression of our deep regret on the event, and of our appreciation of his public services.

Of Dr. Stevenson's contributions to the scientific journals we shall say nothing, except that these would have sufficed to secure a permanent place for him in the history of statistical science. The searching and illuminating discussions of the problems of vital statistics which he has contributed to the census reports and to the annual and decennial reports of the Registrar-General have formed noteworthy landmarks in the study of our national records. Dr. Stevenson's remarkable analysis of the data of the census of fertility, taken in 1911, was a tour de force, while the essays contributed by him to the annual reports of the Registrar-General make a wider appeal and, in our judgment, place Stevenson second only to William Farr amongst those public servants who have secured for England her proud position in the realm of official vital statistics. His studies of the factors of infant mortality, of the local distribution and evolution in time of mortality from tuberculosis, and of the interpretation of the statistics of cancer mortality, especially in relation to its local incidence in the human body, are further examples of immensely important medical research. Dr. Stevenson first demonstrated, upon adequate data, the contrasting rates of mortality of single and married women from cancer of the breast and reproductive organs. This and his more recent studies of the variation of cancer mortality with social status constitute probably the most important statistical contributions yet made to our knowledge of malignant disease.

In these, as in many other instances, Dr. Stevenson approved himself a worthy successor to Farr, and there has been secured that continuity of research into medico-social problems of which the Registrar-General's records form an almost unlimited storehouse. We offer this imperfect tribute to the merits of a great public servant in the hope that our readers may reward him in the way he would most value—by studying these records of first-rate investigation for themselves, and be stimulated to similar inquiries based on our scantily used records.

We are, Sir, yours faithfully,

DAWSON OF PENN.
MOYNIHAN.

IMPRISONMENT FOR MENTAL DISORDER.

To the Editor of THE LANCET.

SIR,—Your readers may remember a letter from Dr. Frederick Dillon[1] drawing attention to the case of a lad who had accused himself of murder, and, after the police had searched in vain for the corpse, been discharged with a warning not to do it again. Dr. Dillon pointed out the risks attached to the absence of psychological investigation of such a case, and the validity of his contention was shown when the same youth later reappeared in court after an attempt at arson.

A similar need of psychological investigation is exemplified in to-day's papers. A young man, said to be the owner of a flourishing business, was sentenced at Hove police-court to 14 days' hard labour for the theft of a motor-cycle. His behaviour had been extraordinary, and apparently inexplicable, and the defence—carried on by his relatives without legal or medical aid—was "loss of memory." The newspaper accounts show that both the Mayor of Hove, who tried the case, and his clerk made kindly—but, of course, unsuccessful—efforts to obtain from the man an explanation of his conduct, and there seemed no alternative to imprisonment. The descriptions accord with a typical fugue state, which apparently still continues, and urgently demands skilled handling, but no one in connexion with the case seems to have had any conception of such a possibility. Nor would there be any certainty of more understanding if the man had been remanded for medical examination; for how many of us are sufficiently acquainted with modern psychological principles and technique to understand a fugue state? It would be wrong to blame the police or bench, and on the legal aspects of the case I can offer no opinion; yet, if my hypothesis is correct, it is distressing to think of this man being placed in prison with no hope of his mental condition being recognised or treated.

I am, Sir, yours faithfully,

London, W., August 7th, 1931. MILLAIS CULPIN.

TRAVELLING IN RUSSIA.

To the Editor of THE LANCET.

SIR,—It is only fair to warn any scientific man—especially a medical man—who proposes to go on a scientific tour organised by the Society for Cultural Relations with Soviet Russia to make sure in London before leaving that he will see that class of subject which interests him, because he will be on a "conducted" tour, where many names are called out, and where he is hurried from place to place. This, though interesting, does not deal with any particular subject. So far, I have seen nothing (according to programme) of medical interest. Though a medical man, starting with an assurance that I should see subjects of medical interest, especially, I am allowed to see only plants and laboratories, and to meet men with long and unpronounceable names, who have no connexion with medicine. Possibly things may be better later, but as we have no programme I cannot be sure. There was a programme, but it was not adhered to.

If there are any so-called "eminent" men in the party, even though in the minority, their subjects are attended to. The wishes of the majority count for nothing, and it is an extremely arduous and rough tour. Hence, unless the tourist's interests are similar to those of the big men the tour may not be worth it.

Beyond that, if interested in seeing what the country is doing, the tourist will have a very interesting time indeed. So far as culture goes, he can get far more in London. The S.C.R. looks after the tourists extraordinarily well, and with extreme patience. "Intourist" (the Soviet organisation for touring parties) gives no assistance whatever, except to the big men, and I can get no information of routes, costs, or anything from it.

---

THE ADEQUATE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—I fear that by the time this reaches you the interest aroused by the discussion in your columns on the adequate treatment of syphilis may have evaporated. Certain aspects of the subject appear to me to be so important that I trust you will allow me a little of your valuable space.

With all respect, I am of opinion that the divergence of views expressed in the letters of Colonel Tyler Burke, Colonel Harrison, Mr. David Lees, and others is of little moment. Their letters suggest that there is a wholesome dread of arsenicals being likely to cause neuro recurrences, and claims are made that by the simultaneous or alternate administration of bismuth or mercury, or both, these risks are avoided.

The essential point is that the statistics given are not concerned with the end-results. I had the Medical Research Council's paper, No. 132, sent out to me in the hope that I should find some help and guidance, but was disappointed to find that it could give me no assistance.

In the early part of this year a three-day conference was held in Nairobi by the Kenya Branch of the British Medical Association to consider syphilis, and I was requested to open the discussion on treatment. I found myself in a very difficult position. I had to ask myself whether I could conscientiously advise an intensive campaign on the lines prescribed by the V.D. authorities in England, or should I rest satisfied with suggesting that attention should only be given to obviously contagious cases and to women who had had miscarriages which could be attributed to lues. I felt obliged to join issue with the controversialists and panicmongers, who write as if syphilis *remains* an infectious disease. No one with adequate experience doubts that infectivity does disappear. I am not forgetting that Warthin says that he has never found a case of cured syphilis at autopsy, but collections of spironemata in the aorta or meninges are a source of danger only to the patient. The Wassermann and other serological reactions are of little help, for contagion is present before there is a serum change, and positive reactions are present when the stage of infection has passed.

In this colony syphilis in the African is a mild disease. Tabes and G.P.I. are exceedingly rare, and Vint, in Kenya, and Webb and Holliday, in Uganda, have shown that aortic disease and aneurysm are much less common than in Europe. It may be taken for certain that few, if any, African patients have completed a course which the high authorities mentioned would consider "adequate," and a huge number of luetics have had no treatment at all. Yet the clinical results, so far as they can be ascertained, appear to be very close to those found byBruusgaard in his analysis of the patients under the care of Prof. Cæsar Boeck, from 1890–1910, who were permitted to combat the disease solely by their tissue reactions, without any specific treatment. This analysis was made from 1925–1927.

Permit me to recall some of Bruusgaard's figures. He traced 471 of Boeck's patients. Of these, 164 had died. One-third of the fatalities were caused by pulmonary tuberculosis and cancer; 25 per cent. had succumbed to cardiovascular disease (a very large majority of these being between 40 and 60 years of age). There were only five deaths from G.P.I. and tabes. Of the 307 survivors, no fewer than 200 were symtom-free. Of these, 68 gave a positive Wassermann. My dilemma can be appreciated, and I finally decided that until we have end-results of cases "adequately" treated by modern methods it was impossible to make a dogmatic statement. It is now more than 20 years since "606" was introduced, and the time is ripe to start a systematic follow-up. If we can get accurate statistics of the fate of 1000 patients the subject will be in a very different position. In every case the condition of the cardiovascular and central nervous systems must be evaluated by experts. A serologist will also be necessary. These workers should be selected by the Medical Research Council, and should be free from the routine duties of a V.D. clinic.

Such statistics as are contained in Paper 132, and others referred to in the discussion, are of little interest outside the clinics where they were collected. We all know that early involvement of the central nervous system occurs, as amply proved by Parnell and Fildes, at Haslar, early in the war. Most of us know, however, that it is unlikely that G.P.I. or tabes will occur within the period of the observations of Colonel Harrison's assistants, and others. This is amply proved by a study of Bruusgaard's patients, who were observed up to 20 to 30 years after their infection. The same holds good in respect of cardiovascular disease.

Probably some of the statistics now available may be made the starting-point of the follow-up inquiry. If this were not so one could only regret that so much time and expense had been lavished upon them. Paper 132 is a case in point. Surely, it is unnecessary to investigate the occupation of male patients—in them, at least, syphilis is not an occupational disease—and the prevalence of congenital lues in paintmakers, photographers, or pianoforte-tuners has not even a sociological interest. But I suppose even the M.R.C. nods sometimes.

I am, Sir, yours faithfully,

JAMES H. SEQUEIRA, M.D.,
F.R.C.P. Lond., F.R.C.S. Eng.

Kenya Colony, B.E.A., July 15th, 1931.

RECOVERY FROM STREPTOCOCCAL SEPTICÆMIA.

To the Editor of THE LANCET.

SIR,—I am quite sure that Dr. Ryle and myself are in complete agreement as to our aims. They are accurately stated and the position well summarised in your leading article on p. 252 of the issue in which his letter appears. Dr. Ryle has laid stress on clinical symptoms in a disease which I consider requires more investigation bacteriologically before we can correlate the symptoms and the nature of the bacterial infection. For instance, I am well aware that one or more of the symptoms which Dr. Ryle has called "a diagnostic syndrome," may occur in hæmolytic streptococcal infections, but before applying the term syndrome it is necessary to prove that the symptoms occur *collectively* in a large percentage of the cases. Within the last few weeks I have had two fatal cases of septicæmia. Neither had a single symptom of the syndrome, yet each had hæmolytic streptococci in the blood stream. Unless emphasis is laid on such cases as these we shall not get a blood culture and a complete bacteriological examination made in every case of continued fever, which is the point which Dr. Ryle and I are both trying to insist upon.

If Dr. Ryle objects to my utilising the Guy's Hospital figures of six recoveries out of 21, because some of the patients had other grave diseases, I would refer him to the statement in his own article, that, after elimination of the five cases in which septicæmia complicated another disease, two-thirds of the remaining group died. This was enough to warrant the only conclusion we drew, viz., the high fatality-rate of streptococcal septicæmia. Obviously, the death-rate in a large hospital gives a more accurate representation of the death-rate generally than does a series of nine cases taken from a consulting practice.

Dr. Ryle now states that his conclusions with regard to sera were mainly in respect of the ordinary polyvalent serum. If by this he means the unconcentrated serum, it should be made quite clear that his warning with regard to crippling serum-sickness was only meant to refer to this unconcentrated serum, and does not apply to the concentrated sera which are now available, and which, with ordinary precautions, can be given, and are given, in large doses without deleterious effect.

I am, Sir, yours faithfully,
A. H. G. BURTON.

Public Health Offices, Ilford, August 7th, 1931.

VEHICLES FOR CHEMICAL CONTRACEPTIVES.

To the Editor of THE LANCET.

SIR,—Your annotator on chemical spermicides (p. 257) would find much about the effects, knowledge of which he considers desiderata, in my book, "Contraception: Its Theory, History, and Practice." While something was said therein of the value of the greasy vehicle in contraceptives in the earlier edition, much more has been added in the greatly enlarged and reset edition, which appeared at the beginning of July, and to which it is extraordinary no reference is made either by your annotator or in Dr. Baker's letter.

Dr. Baker suggests that "the superiority of cocoala as a vehicle for chinosol is evident." Is this "a new fat," as Dr. Baker states? If this is the proprietary preparation which has long been known to those concerning themselves with the practical side of contraception, a sad disillusionment awaits the members of the medical profession who take Dr. Baker's assumption of its superiority without clinical test.—I am, Sir, yours faithfully,

MARIE C. STOPES,
President of the Society for Constructive Birth Control and Racial Progress.

Hindhead, Surrey, August 11th, 1931.

*** A review copy of the third edition of Dr. Marie Stopes's book (London: G. P. Putnam's Sons, pp. 487, 15s.) reached us on July 15th. A considerable amount of matter, devoted in the earlier editions to propaganda, has been omitted from this edition, and much interesting information is added upon recently popularised contraceptive methods. The author adheres to her original view that the best available method for normal and healthy women is the rubber cervical cap. For women suffering from uterine displacements and abnormalities of the cervix she recommends a flat rubber sponge, some three-quarters of an inch thick, soaked in olive oil, which the woman is advised to boil for two minutes in salt water after use.—ED. L.

CANCER-PRODUCING SUBSTANCES.

To the Editor of THE LANCET.

SIR,—In view of certain statements which have appeared in the press, the authorities of the Cancer Hospital (Free), Fulham-road, wish to state that no announcement of any kind referring to cancer-producing substances has been issued from this hospital since their official report to the British Empire Cancer Campaign, which was presented at the annual meeting of the Campaign on July 20th. In this report (pp. 33–42) no claim is made that the cancer-producing substance present in tar has been identified.—I am, Sir, yours faithfully,

J. COURTNEY BUCHANAN,
Secretary.

Cancer Hospital, Fulham-road, London, S.W., August 12th.

*** Recent work at the Cancer Hospital on carcinogenetic substances was noticed in an annotation on p. 197 of our issue of July 25th.—ED. L.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs. G. Kirker to *Durban*; J. Hamilton to *Britannia*; and J. Cusson to *Sandwich*.

Surg. Lt.-Comdrs. (D.) A. MacPherson to *Victory*, for Haslar Hosp.; A. Lawrey to *Ganges*; and R. R. Adams and R. S. Ward to *President*, for three months' dental post-graduate course.

Surg. Lt. (D.) H. V. Pell to *Victory XI.*, for R.N. Hosp., Portland, tempy.; F. J. Goldsworthy (actg.) to *Vivid*, for Devonport Barracks; and J. C. Benson (actg.) to *Victory*, for Portsmouth Barracks.

ROYAL ARMY MEDICAL CORPS.

Maj. and Bt. Lt.-Col. T. J. Mitchell retires on retd. pay and is granted the rank of Lt.-Col.

Maj. (temp. Lt.-Col.) F. Casement to be Lt.-Col.

Maj. E. M. Middleton to be temp. Lt.-Col.

Lt. J. W. Kendall to be Capt. (prov.).

ROYAL AIR FORCE.

Flying Officer E. W. B. Griffiths is promoted to the rank of Flight-Lt.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 1ST, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 26 (last week 30); scarlet fever, 1416; diphtheria, 831; enteric fever, 60; pneumonia, 401; puerperal fever, 37; puerperal pyrexia, 114; cerebro-spinal fever, 31; acute poliomyelitis, 13; acute polio-encephalitis, 1; encephalitis lethargica, 14; dysentery, 24; ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 4th–5th was as follows: Small-pox, 51 under treatment, 2 under observation (last week 58 and 2 respectively); scarlet fever, 1216; diphtheria, 1481; enteric fever, 12; measles, 147; whooping-cough, 379; puerperal fever, 35 (plus 4 babies); encephalitis lethargica, 211; poliomyelitis, 1; "other diseases," 130. At St. Margaret's Hospital there were 15 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox or enteric fever, 18 (2) from measles, 4 (1) from scarlet fever, 16 (3) from whooping-cough, 22 (4) from diphtheria, 41 (10) from diarrhœa and enteritis under two years, and 11 (0) from influenza. The figures in parentheses are those for London itself.

Four of the deaths from measles were reported from Barnsley; 4 of those from whooping-cough from Liverpool. Diarrhœa was credited with 5 deaths at Liverpool; 4 at Manchester.

The number of stillbirths notified during the week was 275 (corresponding to a rate of 40 per 1000 births), including 57 in London.

PUBLIC HEALTH SERVICES

PORT SANITARY AUTHORITY.

Dr. W. F. Dearden, in his twenty-fifth annual report to the Manchester Port sanitary authority, mentions that no case of cholera, plague, or yellow fever appeared, that three cases of scarlet fever were removed to hospital, and that single cases of malaria, dysentery, pneumonia, and tuberculosis were treated on board. One child, with scarlet fever, was sent to hospital from a canal boat. On board ships 915 rats were destroyed (the average number per ship was 2½ in 1930, 5½ in 1929, so rats are decreasing on ships), and 2332 on shore; 31 examined were found free of plague. Of the 877 tons of food condemned, 682 were apples, mostly on account of "brown heart," being death of tissue from interference with respiration. Inspection of 1976 ships showed that 502 had defects, 116 forecastles requiring cleaning and painting. There were 85 defects in water-closets, 76 in ventilation, 81 in lighting, 50 in heating, 57 in water storage, while 33 forecastles were verminous. Defects were more numerous in British (30 per cent.) than in foreign ships (15). The crews of vessels inspected averaged 26 men. The chief reported defects in canal boats were leakages into cabins. Like other port medical officers, Dr. Dearden finds better accommodation for seamen on foreign ships than on British ships, especially on new vessels. Having examined 88 British ships and 52 foreign, all built since 1926, he found that the crews' quarters were aft in 76 per cent. foreign, but only in 42 per cent. British; there were washplaces and bathrooms in 76 per cent. foreign and 55 per cent. British, messrooms and hospitals in 94 per cent. foreign, and in barely half of the British ships, the reason being that improved accommodation is compulsory abroad, but at home is recommended only by the Board of Trade, which has no power to compel compliance. It is said, he remarks, that shipping cannot stand fresh financial burdens, but (he asks) would burdens be materially increased if ships were properly planned from the start, and, alternatively, if burdens are thus increased, how do the ships of small nations bear them and still compete with our shipping, which escapes them? He hopes the Board of Trade and Ministry of Health will combine to get statutory authority to make regulations requiring a certain type of accommodation for sailors on British ships. At the same time, suitable water storage should be ordered, and sanitary dust-bins for ships in dock, not coal-burning, and so unable to dispose of their own kitchen refuse. Shipowners and others have recently been conferring about crews' living quarters, and a month ago the President of the Board of Trade stated that the Board would take such action as lay within its power to give effect to their recommendations. If we have correctly understood Dr. Dearden's report, that will leave matters precisely where they are.

MENTAL HOSPITAL REPORTS.

The City of Cardiff Mental Hospital had 749 patients in residence on the first day of this year. The death-rate for the year was 7·7 per cent., and the recovery-rate 39·9 per cent., despite the high percentage (21·7) of admissions for general paralysis—accounted for by the high incidence of syphilis in the seaport. The general health was good, and there was no infectious disease, except one case of scarlet fever, one of erysipelas, and four of tuberculosis. All new female cases were discussed with the gynæcologist, and those whose symptoms pointed to any gynæcological condition were examined by him. A large number of patients were submitted to routine ear, nose, and throat examination, and a certain amount of sepsis was discovered and removed, without, however, any very striking psychical improvement. The dentist attended regularly throughout the year and examined over 500 patients. The consulting surgeon performed three major operations. In the biochemical laboratory a number of interesting pieces of research are being carried on, including work on the carbohydrate and nitrogen metabolism of the psychotic, the psycho-galvanometer, oxidation in the brain, somatic changes, the blood coagulation time, and gynæcological and menstrual conditions in the psychoses. Malarial therapy has been continued, and the results show a discharge-rate of 33·3 per cent. and a benefit-rate of 46·9 per cent. Continuous baths and ultra-violet light treatment have been used together and have seemed to enhance each other. The occupational therapy department has been kept busy. The best occupations officer, in the opinion of this hospital, is the mental nurse with a knowledge of arts and crafts. Some 80 per cent. of the women and 70 per cent. of the men are employed in useful tasks. All ground-floor wards are administered on the open-door principle, and patients in non-observation wards now do not go to bed until 9 P.M., after a light supper. There are 76 men and 111 women on parole, and during the year 162 patients were granted leave of absence on 1374 occasions. After-care work is carried on in coöperation with the Cardiff League of Social Services, but the Medical Superintendent looks to the day when the hospital will have its own full-time social worker. The out-patient clinic at the Cardiff Royal Infirmary has had to open a second weekly session; 82 new patients attended last year. Two unqualified resident clinical assistantships are now available for final year students, and this experiment has proved a great success. During the year five nurses obtained the final certificate of the General Nursing Council. This hospital is in the enviable position of always having a waiting list of suitable applicants for probation.

The East Riding Mental Hospital at Beverley had 610 patients under care on March 31st last. The recovery-rate for the preceding year was 25 per cent., and the death-rate 8·54 per cent. Autopsies were performed in all cases where permission was given—i.e., 96 per cent. Confusional and excited cases are treated by hydro-therapeutic methods with very satisfactory results, and general paralytics, who fail to respond to tryparsamide, are treated with malaria. The dental surgeon visits regularly and examined 161 patients during the year. Parole was granted to 46 patients. A laboratory has been established and equipped, and arrangements have now been made to house the mentally defective children elsewhere. Plans for a new nurses' home have been approved. The staff consists of 39 men, 21 of whom hold the R.M.P.A. certificate, and 38 women, of whom four are certificated.

The Hereford County and City Mental Hospital at Burghill housed 545 patients at the end of last year. The recovery-rate for the year was 25 per cent., and the death-rate 5 per cent.; post-mortem examinations were held in 59 per cent. of the fatal cases. The visiting dentist extracted 363 teeth. The general health was good, and there was no infectious disease, except two cases of erysipelas and one of diphtheria. Parole within the grounds is granted to 29 men and 11 women, and six men are allowed outside the estate. One male and two female wards are "open door," and periods of trial are practically always given before discharge, though not very often with a money allowance. Of the nursing staff of 72, 11 men and 14 women are certificated or registered, but considerable difficulty is experienced in procuring candidates.

At the Joint Counties Mental Hospital for the Counties of Carmarthen, Cardigan, and Pembroke there were 652 patients on March 31st last; the hospital is overcrowded. The recovery-rate for the year was 33·3 per cent., and the death-rate 11·9 per cent. The general health caused some anxiety, as influenza was very prevalent, and there were 19 cases of diarrhœa or enteritis, 6 of tuberculosis, and 23 of peripheral neuritis—the cause of which is still obscure. The dentist visits weekly, and treated 160 patients, but the absence of electricity in the institution deprives the patients of many modern methods of treatment. A new hot-water system has been installed, and a new verandah is being built. The visiting commissioners urge the advisability of allowing more patients out on trial before discharge, and of granting money allowances. A laboratory is to be fitted up. Two nurses passed the final examination for the R.M.P.A. certificate during the year.

There were 796 men and women on the books of the **DOWN COUNTY MENTAL HOSPITAL** at **DOWNPATRICK** at the end of last year. The recovery-rate for the year was 31·1 per cent., and the death-rate 7 per cent. An electro- and hydro-therapeutic equipment is to be added to the hospital, and occupational therapy has already developed considerably, 60 per cent. of the patients being usefully employed. Stress is laid on the manufacture of useful articles, tweeds and linen, for instance. Seventy members of the nursing staff hold the R.M.P.A. certificate.

The **MONMOUTHSHIRE MENTAL HOSPITAL** at **ABERGAVENNY** had 1206 patients on its register at the end of last year. This hospital is one of the few in which the male patients outnumber the female. The recovery-rate for the year was 35·3 per cent., and the death-rate 6·3 per cent. There was no outbreak of infectious disease, but sporadic cases of chronic dysentery and tuberculosis came under care. An out-patient clinic has been established at the Royal Gwent Hospital, at Newport, and 84 new patients were treated during its first year of work. The Medical Superintendent hopes that Maindiff Court will soon become a modern admission and convalescent villa in the sense of the new Act. Plans for a nurses' home have been submitted to the Board of Control. The dentist visited weekly, and extracted 249 teeth during the year. The visiting surgeon was called in consultation ten times, and performed eight operations. Fifty-six men are allowed parole beyond the estate, and 85 men and 26 women are free within the grounds. An X ray apparatus has been installed, and general paralysis is to be treated by induced malaria. Of the 152 members of the nursing staff, 39 men and 20 women are certificated or registered, eight having passed the final examination for the nursing certificate during the year.

PRIVATE MENTAL HOSPITALS.

The report of **THE RETREAT, YORK**, is illustrated, as usual, by charming pencil drawings. During the year 116 patients were admitted, 110 discharged, and 20 died, the number on the books on Dec. 31st, 1930, being 206. Of those admitted during the year, 64 per cent. were on a voluntary basis. The recovery-rate was 37·8 per cent., and the death-rate 8·5 per cent. The Medical Superintendent, in common with every one of his colleagues this year, discusses the Mental Treatment Act, but, in addition to his welcome of the measure, he expresses considerable disquietude at the lack of alteration in the popular attitude towards the mentally ill. As far as he can see, recognition of the modern trend of thought is only made by those most intimately concerned, and there is serious need for a rapid change in the popular conception of mental illness and its treatment. The general health at the Retreat during the year was very satisfactory. The occupational therapy department, under its whole-time instructor, provides every kind of work, and is gathering more and more patients into its happy activity. A seaside house was again taken for the summer. A seven-seater motor-car has been bought to take patients for excursions into the country; it is in regular use every morning and afternoon. Garrow Hill is being altered to form a nursing home, to be run in connexion with the Retreat. The visiting commissioners suggest the installation of an X ray apparatus. Six gentlemen and 12 ladies have parole beyond the grounds, and seven gentlemen and 16 ladies within the grounds. During the year three nurses passed the final examination of the General Nursing Council. Nine female nurses are employed nursing male patients.

The 104th annual report of **JAMES MURRAY'S ROYAL ASYLUM, PERTH**, illustrated by photographs, records a successful year of progress. There were 178 patients on the register on March 31st last, the ratio of voluntary to certified patients admitted being 40:24. The new detached hospital block—Gilgal Hospital—has been completed and is now open for voluntary patients, suffering from slight or brief neuropathic or psychopathic disorders, who are sensitive or apprehensive about association with invalids of a different type. The building has been equipped in the most modern style. Each ward unit consists of a dormitory with 8 to 11 beds, a day room, dining room, six private rooms, three observation private rooms, two bath rooms, with a continuous bath, a clinical treatment room, a verandah, and offices. The death-rate at the James Murray's institution last year was 8·1 per cent., and post-mortem examinations were made in five out of the 14 cases. Of the 50 patients discharged during the year, 21 were recovered and 26 relieved. The damage done by the fire in April, 1930, has now been made good, and the whole system of water-mains has been renewed. The commissioners comment with gratification on the amount of parole allowed. During the year four nurses and two attendants obtained the R.M.P.A. certificate, and three nurses and one attendant passed the final examination of the G.N.C. The hospital has reluctantly abandoned the examinations of the R.M.P.A., as that certificate does not entitle the holder to a place on the State register.

At **BARNWOOD HOUSE, GLOUCESTER**, there were 139 certified patients and 17 voluntary boarders on Dec. 31st, 1930. The hospital has been very full on the female side, but there have been fewer men admitted than during previous years. Had there been more accommodation there would probably have been many more voluntary patients. The recovery-rate for the year was 57·7 per cent., and the death-rate 5·04 per cent. The discharges included one case of general paralysis treated by induced malaria. The general health was good, and there were but few cases of influenza. A permanent occupations officer has been appointed, and it is hoped that this department will develop. Parties were taken to the seaside in the summer and accommodated at a large private hotel. Pathological work is carried out at the Gloucestershire Royal Infirmary. The cinema installation is now in working order and is very popular. An ultra-violet ray installation has been supplied. Twelve patients have full parole beyond the grounds, and 12 more within the grounds. During the year seven nurses passed the final examination of the R.M.P.A., bringing the total certificated to 78 per cent. of the men and 35 per cent. of the women.

ENLARGEMENT OF WELLHOUSE HOSPITAL.—A new block, containing two theatres, has just been added to this poor-law institution at Barnet, which is the largest hospital in Hertfordshire. The cost of erection and equipment was £13,000.

HOSPITAL EXTENSIONS.—The Duke of Connaught recently opened, without ceremony, two new wards at the Children's Hospital, Hampstead.—A fortnight ago Lord Apsley reopened Cirencester Memorial Hospital after its enlargement at a cost of £14,000. The work includes the addition of 14 beds, making a total of 42, with accommodation for another 14 in an emergency, the improvement of the private wards, and additions to the domestic amenities.—About the same time Viscountess Allendale opened the new women's wing of the Wakefield Clayton Hospital. The wing, which contains 48 beds, is the gift of Mr. S. Canning Childs, of New Jersey, U.S.A., who is a native of Wakefield, in memory of his mother. This latest benefaction of Mr. Childs, who was present at the ceremony, brings the value of his gifts to Wakefield to £63,500.

OBITUARY

DONALD MACPHAIL, M.D., F.R.F.P.S. Glasg.

Dr. Donald Macphail, who died on August 2nd, at the age of 77, had been living at Hamilton since he retired from his practice at Coatbridge, Lanarkshire, some seven years ago. He was a graduate of Glasgow University, and on qualification in 1877 took up house appointments at the Western Infirmary under Sir William Gairdner and Sir George Macleod. After a year as resident assistant physician at the Belvidere Fever Hospital he began to practise in Glasgow, and became assistant to Sir George Macleod, then Regius professor of surgery. From early student days he had been an earnest worker, and in association with the late Dr. David Newman and Prof. Joseph Coats he was responsible for starting what afterwards became the clinical and pathological laboratory of the Western Infirmary. Here and elsewhere the scientific trend of his thoughts was clearly evident. When still an undergraduate and president of the University Medico-Chirurgical Society he selected Darwin's "Origin of Species" as the theme of a presidential address at a time when evolution was barely clear on the horizon. In the pathological laboratory he made inquiry into the chemical composition of diseased bone, and devised an ether percolator which economised both time and material. While at Belvidere, he undertook a review of the hospital figures for the eight years preceding 1879, in order to elucidate the seasonal fluctuations of typhus and enteric fever, and the movement in their mortality-rates. To this subject he returned in the *Glasgow Medical Journal* for 1893, in order to demonstrate the possible fallacies of comparing different modes of treating enteric fever without reference to the natural fluctuations in the severity of the disease. To the *Proceedings* of the Pathological and Clinical Society of Glasgow, now merged in the Royal Medico-Chirurgical Society, he was a frequent contributor.

DR. DONALD MACPHAIL.

[*Photograph by Annan.*

Most of Dr. Macphail's life, however, was to be spent in general practice, and within a couple of years he had left Glasgow for Coatbridge, to become surgeon to the employees of two of the large ironworks for which the district is famous. As works' surgeon he began courses of first-aid and ambulance training, which were at that time a novelty, and this was a branch of his activities which he followed for very many years both as a lecturer and examiner. Of his principal occupation it is less easy to write. "To the family doctor, whose energies are wholly absorbed in his work," writes a colleague, "the goal is reached when he wins the friendship and esteem of his patients, and this Dr. Macphail earned and won in full measure. Innate modesty made him indifferent to an evanescent popularity, but the solid esteem in which he was held by his fellows was shown many years ago when, on the opening of the Alexandra Hospital, Coatbridge, he was appointed one of the first operating surgeons. On retirement from practice he was entertained at a public dinner by his fellow-practitioners and other friends, and a few years ago he was elected, without examination, to the Fellowship of the Royal Faculty of Physicians and Surgeons." Outside his work he was a highly accomplished pianist, and took pleasure in sketching.

Dr. Macphail's family, in the present generation, has been closely connected with medicine. A younger brother, Dr. James Macphail, went as medical missionary to the Santals, and his work is now being continued by his nephew. Another brother is Dr. Alexander Macphail, of the Ministry of Health, while yet another, Dr. John Macphail, practised at Barnsley, Yorkshire, until his death a few years ago. One of his daughters, Dr. Katherine Macphail, was the founder, and is now director, of the British Hospital for Children at Belgrade, Yugoslavia.

JOHN ROBERT LORD, C.B.E., M.D., F.R.C.P. Edin.

We regret to announce the death, on Sunday last, after a brief illness, of Lieut.-Colonel J. R. Lord, medical superintendent of Horton Mental Hospital, within a day or two of his 57th birthday. By his death psychiatry loses an ardent and valued worker.

COLONEL LORD.

[*Photograph by Claude Harris.*

John Robert Lord was born at Blackburn in 1874, and educated at the Grammar School there, and later at Owens College. He went on to Edinburgh for his medical studies, during which he organised the University battery of the City Artillery. After qualifying M.B., C.M. in 1896, he became assistant demonstrator in pathology at the School of Medicine. He took his M.D. in 1926 and also the M.R.C.P. Edin., being elected a Fellow of the college in the same year. Under the influence of Clouston he became interested in the study of psychological medicine, and in 1897 held his first appointment as assistant at Carmarthen Mental Hospital to Dr. Edwin Goodall, with whom he kept up a life-long association. In 1898 he entered the mental hospital service of the London County Council, first at Hanwell, and then at Bexley, where he was deputy superintendent. Full charge came to him at the early age of 33, when he was appointed superintendent of Horton Mental Hospital, Epsom. From this time on his whole life and activities centred round the study of mental disorders, with the exception of the years 1915–1919, when he was officer commanding the Horton War Hospital, during which time 45,000 officers and other ranks received treatment. He rose to the rank of Lieut.-Colonel, R.A.M.C., was mentioned in despatches, and received the C.B.E.

Colonel Lord made many contributions to the branch of medicine in which he specialised. His early work was on epilepsy and the study of the pineal gland, along with some anthropometrical research. He was bronze medallist of the Royal Medico-Psychological Association, and his literary contributions dealt with Social Workers and the Insane, the Clinical Study of Mental Disorders, Mental Hospitals and the Public, and the Evolution of the Reception Orders for Mental Patients in England and Wales. At Horton, Colonel Lord was able to put into practice many of his ideas. He was a pioneer in the development of the villa system, and extended it to convalescent villas; he organised a modern type of admission hospital, established one of the first occupation therapy centres, and coöperated with the Ministry of Health in the founding of a malaria therapy centre for the treatment of general paralysis. His work for the Medico-Psychological Association was of outstanding value. From 1900 he was assistant editor of the *Journal of Mental Science*, becoming co-editor in 1911, his keenness contributing largely to bringing that journal to its present high scientific standard. In 1926, after serving for many years on its council, Colonel Lord was elected president of the association, and, as a result of his inaugural address, a research and clinical committee was formed, with himself as chairman. Whilst giving time and energy without stint to work on this and the educational and parliamentary committees, Colonel Lord, during the last ten years, found wider outlet for his activities. He was honorary secretary of the National Council for Mental Hygiene, and latterly a member of the General Nursing Council. In 1930 he went to America to attend the first International Congress for Mental Hygiene. He was elected an honorary member of the Belgian and French psychological societies. In 1928, under the affiliation scheme, he was made lecturer in mental diseases to the London (R.F.H.) School of Medicine for Women.

At Horton, Colonel Lord was regarded as an administrator of outstanding ability; he certainly realised his aim of making the hospital rank among the foremost of mental hospitals. "Those of us who had the privilege of working under him," writes Dr. W. D. Nicol, "found him a good chief and a generous friend. It was in 1920 that it was first discovered that he was a sufferer from diabetes, and his courage in the face of great odds was admirable. He not only overcame his disabilities, but he managed to get the best out of life, and he will be remembered as one who did a great work in the cause of psychiatry. It will be difficult to think of this hospital without him."

Colonel Lord found his relaxation in foreign travel and at home in growing roses. In March of this year he married Miss Ruby Carr, an Edinburgh medical graduate on the Horton Hospital staff, with whom he shared his many interests.

MEDICAL NEWS

Royal Colleges of Physicians of London and Surgeons of England.

At the Final Examination of the Conjoint Board, held from July 6th to 28th, the following candidates were approved in the subjects indicated, but are not eligible for the diplomas of the colleges:—

Pathology.—H. Ackers, Liverpool; H. Agar, Leeds; C. F. S. Aiken, Middlesex; G. T. Allen, St. Thomas's; G. N. Barker, St. Thomas's; Mavis W. M. Beddall, Univ. College; H. Blumovitch, St. Bart.'s; G. H. Brookman, St. Bart.'s; D. G. W. Brown, Liverpool; W. Bullock, Liverpool; V. Constad, Guy's; H. V. Corbett, Liverpool; T. A. L. Davies, St. Thomas's; A. H. Dunkerley, Camb. and Manchester; G. E. Dunkerley, Univ. College; F. R. Edwards, Liverpool; G. M. Evans, Bristol; T. A. Gavin, Guy's; K. J. Gilchrist, Guy's; A. M. Gill, Middlesex; J. H. L. Gilmore, M.A. Camb. and St. Thomas's; M. Hafezi G. P. Gladstone, London; F. J. S. Gowar, Middlesex; M. Hafezi St. Mary's; R. J. C. Hamilton, St. George's; H. G. Hanley, Liverpool; Helen A. Hatrick, Univ. College; W. N. Hine, Middlesex; L. A. Hiscock, St. Bart.'s; R. A. P. Hogbin, Guy's; A. Hollingsworth, St. Thomas's; M. S. Holzman, London; W. A. John- A. C. Howard, Univ. College; D. H. Irish, Guy's; W. A. John-son, St. Mary's; T. B. Jones, Westminster; W. H. Jones, Manchester; W. W. Jones, Guy's; E. Kaminsky, Univ. College; K. D. Keele, St. Bart.'s; J. J. Kempton, Bristol; A. Kennedy, St. Thomas's; L. O'N. Knox, Guy's; W. Kravchick, St. Bart.'s; L. W. Lauste, St. Thomas's; I. Levy, Guy's; J. R. M. Martin, St. Bart.'s; J. A. W. Miller, Guy's; M. A. N. Moezuddin, St. Thomas's; J. de C. Muller, St. Thomas's; Irene P. Murray, King's Coll.; P. H. Nankivell, Middlesex; W. T. North, Guy's; R. S. Ogborn, Univ. College; G. B. Palmer, L.D.S., Guy's; J. S. Parkinson, Manchester; R. H. Patel, Birmingham; S. Paul, Guy's; Norah W. K. Petter, Royal Free; W. S. Pitt-Payne, Guy's; C. B. R. Pollock, Guy's; V. T. Powell, Cardiff and Guy's; F. Radcliffe, Camb. and St. Bart.'s; J. C. Read, L.D.S., Guy's; R. G. Reid, Guy's; D. F. Robb, St. Thomas's; P. G. Roberts, St. Bart.'s; R. D. Roper, Camb. and St. Bart.'s; A. Rothwell, Camb. and King's Coll.; H. W. Salmon, Middlesex; O. A. Savage, St. Bart.'s; G. O. Sawyer, Guy's; R. T. Shipman, St. Thomas's; P. Q. M. Spaight, St. Bart.'s; K. W. Stroude, Liverpool; D. J. Swamy, Durham; S. K. K. Sze, Camb. and St. Thomas's; J. R. Thornton, St. Thomas's; E. Troensegaard-Hansen, Charing Cross; A. A. M. Wajih, Charing Cross; A. R. Walters, Middlesex; Clara M. Warren, Royal Free; H. Waterman, Leeds; S. W. Wright, Guy's.

Medicine.—S. S. Alam, M.B. Punjab; A. B. Anderson, Ph.D. Camb., Univ. College; A. Ascher, King's Coll.; T. J. Ashley, Cardiff; G. Ashton, Oxford and Univ. College; M. Bloom, Manchester; H. Blumovitch, St. Bart.'s; L. Bowen, St. Bart.'s; J. R. Braybrooks, Oxford and King's Coll.; I. Cohen, King's Coll.; H. W. Cowen, Camb. and Univ. College; R. A. F. Creet, St. Thomas's; A. S. V. Daniels, L.D.S., Westminster; S. C. De, M.B. Calcutta; Jennie G. Evans, Westminster; F. R. Glover, London; R. A. E. Hammond, Camb. and Guy's; Joan G. Harcourt, Royal Free; Florence D. Hawes, Royal Free; Doris I. Howell, Charing Cross; E. Kaminsky, Univ. College; B. L. Kapur, M.B. Punjab, Univ. College; K. D. Keele, St. Bart.'s; Victoria H. King, Royal Free; H. H. Langston, St. Bart.'s; O. C. Levine, Univ. College; J. MacDonald, M.B. Glasg.; J. A. S. Marr, M.B. Cape, Middlesex; J. R. M. Martin, St. Bart.'s; Oonah L. Matthews, Univ. College; M. T. Maung, M.B. Rangoon, Guy's; I. D. Monger, Wales and Charing Cross; Elisabeth J. Morris, Liverpool; D. R. Narang, M.B. Punjab, London; H. D. Owen, Liverpool; E. Palmer, Camb. and King's College; T. J. Royal College of Physicians of London.

The College will be closed from August 17th till Sept. 19th, both days inclusive.

British College of Obstetricians and Gynæcologists.

The quarterly meeting of the Council was held in London on July 27th, with Prof. W. Blair Bell, the President, in the chair. Prof. J. M. Munro Kerr (Glasgow) and Dr. J. S. Fairbairn (London) were re-elected vice-presidents for the current year. A vacancy for a representative of the Members on the Council, occasioned by the elevation to the Fellowship of Prof. E. Farquhar Murray, was filled by the election of Mr. J. St. George Wilson (Liverpool) for the remainder of the current year.

Dr. T. M. Healy (Dublin) and Dr. Margaret I. Balfour (India) were admitted to the Fellowship *in absentia*.

It was reported that the finance and executive committee had inspected several premises but had so far not found a house in London that conformed to the requirements of the College. It was decided that the annual dinner should be held at Grosvenor House, Park Lane, London, on Oct. 23rd, and that this should be preceded by a ceremony for the conferment of the honorary Fellowship on Lord Riddell, Prof. Paul Bar (Paris), Prof. Whitridge Williams (Baltimore, U.S.A.), and Prof. Essen-Möller (Lund, Sweden), and also of ordinary Fellowships and Memberships.

A Hospital Rate.

The town council of Gillingham, Kent, has decided to levy a rate towards the support of two of the local hospitals. The rate is expected to produce £585, of which £300 is to be allocated to St. Bartholomew's Hospital, Rochester, and £105 to the Kent County Ophthalmic and Aural Hospital at Maidstone.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE ASSOCIATION, 1, Wimpole-street, W.

Monday, August 17th, to Saturday, August 22nd.—All Saints' Hospital, Vauxhall Bridge-road, S.W. Special post-graduate course in Urology. Afternoons and some evenings. Demonstrations and cystoscopies.—Queen's Hospital for Children, Hackney-road, E. All day course. Medical and surgical demonstrations. Two weeks.—Further particulars from the Fellowship of Medicine.

ST. MARK'S HOSPITAL, *City-road*, E.C.

Thursday, August 20th.—4.30 P.M., Mr. E. T. C. Milligan: Modern Surgery of the Colon.

Appointments

Ackerman, W. L., M.D., M.R.C.P. Lond., has been appointed Resident Medical Officer of Brighton Infirmary and Warren Farms Schools.

Drum, E. F., M.B., Ch.B. N.U.I., Asst. Superintendent, Peamount Sanatorium, Dublin.

Gebbie, N., M.D., Ch.B. Glas., D.P.H., M.O.H., Hull.

Main, F. F., M.B., Ch.B. Edin., Asst. M.O.H., Burgh of Kilmarnock.

London County Council: Rose, D. F. (Miss), M.A., M.B., Ch.B. Edin., D.P.H., Temp. Asst. M.O., Hackney Hospital; Lindford, H. (Miss), M.D., Ch.B., Temp. Asst. M.O., Mile End Hospital; Morgan, J. (Miss), M.B., B.S. Lond., Temp. Asst. M.O., St. Andrew's Hospital; Sandow, J. F., L.R.C.P. Lond., M.R.C.S., Temp. Asst. M.O., St. James's Hospital; Chamings, R. W. E., M.B., B.S., Temp. Asst. M.O., St. Giles's Hospital; Hicks, J. A. B., M.D., M.R.C.P. Lond., M.R.C.S., Pathologist, Lambeth Hospital Group Laboratory; Barnard, W. G., M.R.C.P. Lond., M.R.C.S., Histologist, Southern Group Laboratory; Allott, G. N., M.R.C.P., Pathologist, Lewisham Hospital Group Laboratory; Goodhart, G. W., M.D., B.Ch. Camb., Pathologist, Archway Hospital Group Laboratory; and Evans, Sir Thomas G. Carey, M.D. Brux., F.R.C.S. Eng., L.R.C.P. Lond., Medical Superintendent, Hammersmith Hospital.

Births, Marriages, and Deaths

BIRTHS.

Jack.—On August 3rd, at Tunbridge Wells, the wife of Lt.-Col. Jack, I.M.S., of a daughter.

Simmons.—On July 31st, 1931, to John and Margery Simmons, M.B., B.S., B.Sc. (née Freeborough), of New Chilterns, Amersham Common, Bucks.—a daughter.

Stott.—On August 3rd, the wife of Dr. W. B. Stott, of Parkleigh, Park Drive, Grimsby, of a daughter.

MARRIAGES.

Highmoor—Cairns.—On August 5th, at St. Mary's Church, Ellon, Richard Anthony Highmoor, F.R.C.S.E., Bramerton, Norwich, to Margaret Combat, youngest daughter of Provost and Mrs. Cairns, Hassendean, Ellon, Aberdeenshire.

MacCormac—Broomhall.—On August 5th, at the Parish Church of Bishops Lavington, Henry MacCormac, M.D., F.R.C.P., to Marion Maud, eldest daughter of Dr. and Mrs. Broomhall, of Tai Yuan Fu, China.

DEATHS.

Andrews.—On August 6th, at Beckmeadow, Mundesley, Norfolk, Lieut.-Col. L. A. A. Andrews (Dombey), late R.A.M.C.

Connolly.—On August 5th, at Kingsdown, Ireland, Colonel E. P. Connolly, late R.A.M.S., aged 54 years.

Lord.—On August 9th, at Horton House, Epsom, Lieut.-Colonel John Robert Lord, C.B.E., M.D., F.R.C.P.E., Medical Superintendent, Horton Mental Hospital (L.C.C.).

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

OSTEO-ARTHRITIS.*

BY PHILIP FIGDOR, M.B. GLASG.,
PHYSICIAN TO ST. JOHN'S HOSPITAL, LEWISHAM; ASSISTANT PHYSICIAN TO THE LONDON TEMPERANCE HOSPITAL.

A GOOD deal of confusion still surrounds the subject of osteo-arthritis. This is partly because most of the work that has been done has been directed towards finding a specific remedy, while the disease itself has not yet been adequately studied and described. Different writers attach different meanings to the term osteo-arthritis, and the result is extremely confusing to anyone who consults their text-books.

In 1913 Sir Thomas Horder [1] suggested the classification of chronic arthritis into two main groups:—

1. *Osteo-arthritis*, mostly single joint affections affecting elderly people, with early bony changes.
2. *Rheumatoid arthritis*, mostly a polyarticular disease affecting younger people and with inconspicuous bony changes.

I find myself in agreement in principle with this classification, except that I would divide my two groups into (1) osteo-arthritis or mono-arthritis, and (2) polyarthritis.

The term polyarthritis is becoming increasingly popular with European writers. There are several distinct forms of polyarthritis, and some of them are definitely not what is understood by rheumatoid arthritis. In fact, rheumatoid arthritis is a term which is not used so much as formerly, and should be discarded.

Radiological Appearances.

Our present state of knowledge of osteo-arthritis owes a great deal to radiology, which enables us to differentiate it from other forms of chronic arthritis. A clinical diagnosis of osteo-arthritis can always be either confirmed or excluded by X rays.

I regard Thomson's [2] description of the X ray appearances as a standard. He states that cyst-like structures are seen in all radiograms of osteo-arthritis, and tend to be massed together in localised areas of bone, forming what he calls "storm centres of disease." He claims that acute clinical symptoms (presumably pain) can always be shown to be associated with activity of one or more cyst-like formations on the joint surface. He goes further and states that, in joints without acute clinical symptoms, active cyst-like foci are not seen on the joint surfaces.

Clinical experience shows that there is some basis for this statement. Every now and again one comes across a case where it is accidentally discovered that the patient has definite, even advanced, osteo-arthritis and denies that he ever felt a twinge of pain or stiffness.

A brawny navvy of 50 injured his left knee while digging in the street. On the following day he had an acute synovitis and was sent to hospital for X ray examination to discover if there was any fracture. There was no fracture, but the radiologist reported an advanced degree of osteo-arthritis of the knee-joint. When I saw him, a few days later, I put it to him that he must have had pain in the joint before his accident. This he strenuously denied, pointing out that he had been a labourer, chiefly on road work, all his life. He had pain and limitation of movement of the knee-joint, of course, while he had synovitis, but after a few weeks his synovitis cleared up. Although he had coarse grating in the joint, he had full and free active movement of the joint and said he had no pain. He then returned to his work and, although he promised to return to see me if he had any pain or stiffness in the knee, he has not done so. Presumably he has remained well, although it is now four years since he attended hospital.

A somewhat similar case is that of a man, aged 62, a ship's rigger, who wrenched his left elbow while at work. A radiogram taken on the following day showed advanced osteo-arthritis of the elbow-joint. Here again the man denied previous pain or incapacity, pointing to the fact that his elbow had to function perfectly as he has to do a lot of climbing at his work.

Thomson [2] visualises two distinct and separate radiographic stages: (1) A primary stage, either cystic or granulomatous in type. This leads to erosion of joint cartilage. (2) A secondary stage of villous and osteophytic changes, which may result from such a mechanical erosion. He emphasises the fact that he considers the cyst-like formation to be the important radiographic sign, and almost pathognomonic. The osteophytic out-growths he believes not to be an essential part of the disease, but a product of the patient's reaction, an effort of nature to give extra support to or to limit the functions of diseased joints. It is not, radiographically, diagnostic of the disease.

R. L. J. Llewellyn [3] also recognises two stages in the life-history of osteo-arthritis—namely, a primary or pre-osteophytic phase of prolonged duration, the symptoms being those of villous hypertrophy, and a secondary or terminal stage in which bony and cartilaginous outgrowths appear. His view is that osteo-arthritis is a generalised and not a localised disorder. He thinks that it can be prevented from developing in the early stages, and says that osteophytes are shown in one knee and not in its fellow.

This is a point to which I would draw attention. I quite agree that one frequently comes across cases where the X rays show osteophytes in one knee only in the early stages. But my interpretation of this differs from Llewellyn's in that I hold that the appearance or development of osteo-arthritis in the second knee is a traumatic result of increased strain thrown on that knee when the other is more or less out of action.

Ætiology.

Consideration of this subject almost always begins with the words "septic focus," and attempts to find an organism and to supply a vaccine. In the last two decades research has generally been in that direction. As it is only in the last few years that the radiologists have enabled us to label the disease with accuracy, it seems to me that there is still a great deal to be done in the way of bed-side investigation, as distinct from the laboratory. I have investigated 480 cases of osteo-arthritis, all of which have been confirmed by radiographic diagnosis. The accompanying table shows that osteo-arthritis is a disease of middle and advancing age and that females are more affected than males; this is partly, but not wholly, explained by the fact that females live longer. It will be noted from the table that I have not come across a case of osteo-arthritis in a man below the age of 30, while I have had ten cases in women between 20 and 30, some of them in the early 'twenties.

Cases of Osteo-arthritis.

Age.	Male.	Female.	Total.
20–29	—	10	10
30–39	10	37	47
40–49	58	75	133
50–59	58	56	114
60–69	72	70	142
70–79	18	14	32
80 and over	2	—	2
	218	262	480

I believe that osteo-arthritis is traumatic in origin, or rather, that the exciting cause is a trauma. In my cases 207 out of 480 gave a definite history of an injury, sometimes several years before the onset of osteo-arthritis. But, in stating that osteo-arthritis is traumatic in origin, I bring in stress and strain as evidence of trauma, as well as injury. Many cases with no direct history of injury or accident come into this category.

A man of 58 came to hospital with pain in the left shoulder, going down to the fingers, of three months' duration. X ray showed a moderate degree of osteo-arthritis of the shoulder-joint. He had never had an injury, but on inquiry I found that he had been an engineer but, owing to inability to get work at his trade, he had for the last three years been a telephone labourer, which meant carrying a 30-lb. bag of tools on his left shoulder.

---

* Abridged from a lecture to the Fellowship of Medicine.

A man, over military age, drove a general in France during the war for eleven months. The car was a powerful one and had a very stiff clutch. He said that he used to have pain in his back at the end of a day's driving. When he gave up driving the car the pain left him. However, several years later when I saw him, he had severe pain in his back and an X ray showed advanced osteo-arthritis of his left sacro-iliac joint.

A man who had been an all-round athlete took up fencing when he reached the middle 'forties. He entered into it with such zest that he became a champion. I saw him when he was 62, and he had not been able to fence for some years because he had osteo-arthritis in both hip-joints, more on the right than on the left. The pathological factor in this case is that a strain was put on joints in middle age to which they were not accustomed. It is fairly safe to say that, had he been a fencer from his youth upwards, he would not have developed osteo-arthritis of his hip-joints.

Osteo-arthritis usually attacks only one joint (excluding the vertebræ). If two or more are affected, close investigation will establish that symptoms began in one an appreciable time before the second, and X rays will confirm this. The cause of the second joint being involved is traumatic—e.g., an osteo-arthritis in one hip-joint will cause the patient to put an increased load or strain on the other hip-joint and will, in untreated cases, cause osteo-arthritis there.

In my series there are 12 cases where both hip- and knee-joints were affected; in six the hip-joint was affected first and in the other six the knee-joint. It is noteworthy that osteo-arthritis occurs in the women who have a rapid and heavy increase in body-weight before or at the time of the menopause. In my series of 100 cases of osteo-arthritis of the knee-joints in women only 28 gave a history of injury.

The type of direct injury that causes osteo-arthritis is more obvious. A young man dislocates his shoulder. The dislocation is reduced and he has no further trouble. A middle-aged or elderly man has his dislocation reduced and in a variable number of months or a year or two he develops an osteo-arthritis of the shoulder-joint. A similar result frequently follows a fracture of the upper end of the humerus. A workman has a fall, or is struck on the back. He is taken to hospital and is X rayed, with negative results as regards fracture. In many of these cases osteo-arthritis of the spine develops later.

It is trauma in the middle-aged and elderly that produces osteo-arthritis. Similar traumata in the young do not.

In my series of lumbar and sacro-iliac osteo-arthritis in women, 36 out of 46 had no history of injury, but 26 had had gynæcological operations and two had had hæmorrhoid operations. Eight of these 28 had had pain in the back before the operation, but the others had not, and in all the other 20 pain in the back came on within a few months of operation, and the X ray showed sacro-iliac osteo-arthritis. I incline to the view that this was due to injury to the sacro-iliac joints at the time of operation, in placing the patient into position for operation, or in letting the legs down afterwards.

“ Malignant Arthritis.”

Osteo-arthritis, like cancer, attacks the middle-aged and elderly—i.e., the physiologically dying. Trauma in this state produces a pathological change. What is this change? Thomson and other radiologists are emphatic that the process is degenerative and not malignant. But though the radiologists may be emphatic, their task is not always easy.

A few months ago I saw a woman, aged 51, who was clinically a well-established case of osteo-arthritis of the right shoulder-joint. I sent her for a X ray examination to confirm the diagnosis. The radiologist's report was as follows: “ The bone of the upper third of shaft and head of the humerus and of scapula in region of shoulder-joint shows areas of rarefaction. ? Cystic degeneration. Is there any question of secondary deposits in this case? ”

In this case there was no question of any pre-existing malignant disease and yet that was the radiologist's report. Every now and again one gets these reports, particularly from young and inexperienced radiologists.

That the disease does not kill is no criterion. It causes such severe pain and is often so resistant to any treatment that one is almost justified in labelling it “ malignant arthritis.”

To those who still think in terms of oral sepsis, it can be pointed out that the disease attacks people who have reached the age of double dentures, and, in those who have teeth, extraction of the remaining teeth seems to make very little difference. As a matter of fact, osteo-arthritis seems to attack mainly people who have led healthy, active, temperate, and even abstemious lives. The intemperate form a very small proportion of these cases. These people deserve a good deal more sympathy than they receive. The pain of osteo-arthritis is one of the most severe that any disease produces, yet the victims, because, as they say, “ they have nothing to show for it,” are enjoined by their friends (and often by their doctors) to exercise the joints or they will get stiff and have more pain. Of course, the more they exercise the worse the pain.

Diagnosis of Osteo-arthritis.

It is, of course, very important to diagnose the condition as early as possible, for the prognosis depends very largely on that. Now, particularly in the case of the shoulder- and hip-joints, the first symptom is generally a pain, not located at or near the joint itself but in the muscles below the joint—i.e., a referred pain. A good proportion of these cases come to the hospital with a diagnosis of “ neuritis.”

In my series 128 out of 145 cases of osteo-arthritis in the shoulder-joint had referred pain down the arm, mostly pain from the shoulder to the elbow; and in the hip-joint 54 out of 64 had pain down the thigh, sometimes to the knee, and a few had pain in the knee-joint only. This referred pain is not only an early symptom, but it is the main symptom throughout the history of the case until, in fact, the disease is arrested. In the knee-joint pain is generally confined to the knee. Only a small minority complain of pain radiating down the shins. In sacro-iliac and lumbar osteo-arthritis, the pain is generally confined to the lower back, but some cases reach hospital diagnosed as sciatica.

Limitation of movement of the joint is usually early. In the hip-joint and shoulder-joint abduction is the chief restriction. As the disease progresses, there is a functional ankylosis. I have come across an occasional bony ankylosis in the hip-joint, but most authorities deny that this ever happens.

Grating occurs in the knee-joints, but is not diagnostic, because it also occurs commonly in healthy joints. The same remark can apply to the early stages in the shoulder-joint. The knee-joint, however, does become definitely enlarged, particularly—judging by its appearance—the lower end of the femur, giving the knee a characteristic look.

The gait of a person with osteo-arthritis of the hip-joint is a characteristic waddling, with almost nothing to distinguish it from that of a case of congenital double dislocation of the hip-joint. Muscular wasting occurs, but it is seldom a gross wasting and sometimes is not very apparent.

A PATHOGNOMONIC SIGN.

In observations previously published,[4] I have noted what I believe to be a pathognomonic sign of osteo-arthritis in the lumbo-sacral region, including, of course, the sacro-iliac joints. When the patient lies on his face and the lumbo-sacrum is palpated with the flat of the fingers, there is a characteristic flabby, “ penetrating ” feel of the wasted lumbar and sacral muscles, giving one almost the impression that one is palpating the bare bone. There is no tenderness on palpation. It is difficult to describe the tactile sensation one receives, but I believe it to be pathognomonic. Of the 86 cases in my series every one had this sign.

Treatment.

I have elsewhere [5] defined a specific therapeutic agent as “ one which, used in a particular, definite, and specified form—e.g., in a drug of a definite chemical composition—and applied in a particular, definite, and specified way to a particular, definite, and specified disease or pathological condition, secures a relief from symptoms and a return to normal and active function of the body or part, excluding permanent tissue damage." According to that definition, there is no specific remedy for osteo-arthritis.

Claims have been made that particular micro-organisms are the cause of osteo-arthritis, but Koch's postulates have not been fulfilled.

Warren Crowe[6] believes in the view, advanced by many workers in the last two decades or so, that streptococci are the cause of osteo-arthritis and non-articular rheumatism. He stresses the numerous varieties of streptococci and the difficulty in differentiating them. In treatment, therefore, in order to make certain that the several streptococci infecting any given patient are included, he advocates the use of a stock streptococcus vaccine, containing the greatest possible number of different streptococci.

My own view, and one that I take care to emphasise to patients, is that the most important part of treatment is rest. The affected joint must be rested. Future restoration of function of the joint is, in my belief, a secondary consideration to getting rid of the pain. The first object of treatment must be to ease the patient of the sometimes intolerable pain he suffers. I am against any forcible movement of the joint, as it sometimes lights up the disease again. Some cases where the pain has entirely ceased but where there is almost an ankylosis of the joint, in the course of a year or two (sometimes a few months), with freedom from pain, achieve an almost complete restoration of function of the joint by the patient's own natural efforts.

In osteo-arthritis of the shoulder-joint, the arm should be placed in a complete sling, with the elbow well supported, so that all weight is taken off the shoulder-joint. It is surprising what relief this simple procedure often gives. It is not easy to achieve rest of the hip- or knee-joints while the patient is going about. In some cases a walking calliper is the only thing that will ease the pain.

I believe that osteo-arthritis is a local and not a general condition, and that local treatment in the form of rest is essential. The application of liniments and pastes to the seat of pain or to the joint is useless. Massage, also, is not only useless but is contra-indicated, as it often increases the pain.

Diathermy is the most valuable form of treatment. The current should be directed to and concentrated on the affected joint and nowhere else, and should be given three times a week for 15 to 20 minutes. Where the patient reacts to this treatment, sometimes as few as half a dozen treatments will give relief from pain of some months' duration, but generally the duration of treatment should be reckoned as many weeks up to several months. I believe that diathermy is the nearest approach we have to a specific remedy for osteo-arthritis. The patient generally finds the treatment very soothing, and it frequently banishes the pain for the time being, even in the early days. Precisely how it acts one cannot determine. Certainly in the majority of cases it seems to arrest the disease process, whatever that may be. The large majority of my cases have done very well with diathermy and require no other form of local treatment.

Every now and again one comes across cases that do not respond to diathermy, but do well with radiant heat or chlorine ionisation, provided that the patient has had a course of diathermy first.

There is one form of general treatment which must be given in all cases, and that is an analgesic or a sedative of some kind until the local treatment has had time to take effect. I generally advise grs. 10 or grs. 15 bromide mixture thrice daily. If the pain disturbs the patient's rest I *do not* hesitate to give a soporific nightly for several weeks if necessary. The most important point of all is the necessity for as complete rest to the joint as it is possible to obtain.

THE TREATMENT OF FRACTURES.

A CONCISE and valuable account of the treatment of fractures and its underlying principles has been prepared by the Fracture Committee of the American College of Surgeons[1] and published in the quarterly *Bulletin* of the College (1931, xv., No. 1). In 30 pages, *copiously illustrated*, a description is given of the normal processes of bone repair, the conditions favouring them, the functions of practitioner and surgeon in promoting them, and the management of many particular varieties of fracture. No attempt has been made to describe operative procedure, the technique of skeletal traction, or methods of local anæsthesia, and the summary is written with an eye to the requirements of general rather than hospital practice. Emphasis is laid especially on the importance of the "emergency initial treatment," the dangers of delay, and the importance of functional restoration. "The treatment of difficult fractures requires the care of experienced surgeons."

The outline concludes with the following series of aphorisms:—

APHORISMS.

Always use gentleness and care in handling any broken limb. Roughness is inexcusable.

Use only the simplest methods of examination for the diagnosis of fracture.

Eliminate all unnecessary handling of the injured limb.

Definite localised tenderness over an injured bone usually is satisfactory evidence of fracture.

Never attempt to elicit crepitus.

Disturb the patient and the injured part as little as possible.

Do not be deceived by the absence of deformity and disability; in many cases of fracture some ability to use the limb persists. Sufficient examination is one which includes a short history, a brief inspection and palpation limited to the localisation of the point of greatest tenderness, coupled with a slight test for false motion.

Do not overlook the responsibility of making a diagnosis. Look for more than one fracture.

An exact diagnosis is absolutely essential to proper treatment and requires suitable X ray films taken in two planes.

Make it a duty to see that the patient has an early suitable X ray examination and competent treatment *thereafter*.

Keep the axes of the ankle- and knee-joints absolutely transverse. When the sole of the foot rests flat on the ground, the top surface of the astragalus should be parallel with the ground.

A stiff shoulder following a fracture of the forearm usually may be prevented. The functional utility of the limb as a whole is a good measure of successful treatment.

Following fracture, the damage of the injury per se must always be reckoned with and deducted from the normal attainable by treatment.

Passive movements affect bone and joint surfaces, often injuring them both. Active movements affect muscles and mind, usually strengthening both. Guided muscular contractions are of primary importance in causing bony union provided, of course, motion of the bone fragments is avoided. Doctors and the public have been taught for ages to keep broken limbs at absolute rest for many weeks.

Apply traction in such a way as to tire the muscles and not produce irritation; that is, make the pull slow, steady, and if necessary increase its force, until the contraction of the muscles attached to the fragments is overcome.

---

[1] 40, East Erie-street, Chicago, Illinois.

Bring the fragment which can be controlled into alignment with the fragment which cannot be controlled.

The circulation distal to the fixation apparatus should be observed frequently during the first three days until all possible danger of increased swelling under snug splinting has passed.

A small insignificant fracture may mean a large disability. Reduce the fracture with as little delay as possible. It is poor practice to wait for the swelling to go down. A primary reduction will give a better result than a secondary reduction.

Examine for nerve lesions and for associated injuries before attempting reduction.

Make an exact diagnosis of the fracture first and then, if necessary, select a splint. A splint may not be needed. Splints are often harmful. No splint is used to reduce a fracture; a splint is intended to maintain reduction. Splints made to fit everybody rarely fit anybody. Make it a practice to splint effectively. When wooden splints are employed use a large amount of padding on the splint.

Treat every case of injury as a fracture until it is proven otherwise. Limit manipulation without an anæsthetic to the correction of the most obvious deformities only, for a broken bone is exceedingly painful and any motion accentuates the pain. Secure the best alignment possible, for the better the alignment obtained in reduction, especially better will be the resulting function.

Mechanical arthritis may result from static faults after partial reductions, in fractures of the lower extremity.

Voluntary active movement of joints contiguous to the fracture as early as possible without disturbing the fracture is highly desirable. Early active movement will prevent the formation of peri-articular adhesions and adhesions within joints.

In the transportation of the patient, do not underrate the importance of temporary immobilisation to relieve pain and muscle spasm and to promote clotting of blood at the bone ends. Continued pain after 24 hours is usually indicative of an incomplete reduction of the fracture or of improperly applied splints.

C.S.M.M.G. REGISTER.

THE register of members of the Chartered Society of Massage and Medical Gymnastics from July, 1920, to May, 1931, contains, besides the list of members of both sexes in the British Isles, information concerning registration, the objects of the society, and the Ling Association. In this issue of the register mention is made of the additional professional qualifications of members of the society, such as nursing, midwifery, educational gymnastics, or dispensing. A new sign indicates whether the member is on the roll of biophysical assistants, established in 1929 by the Society of Apothecaries. Chartered masseuses and masseurs who have qualified through their own society in light and electrotherapy are eligible for admission to this roll without other formality than the payment of the primary registration fee. At the end of the book an index of members, arranged under postal districts, is included; this should be convenient for the use of medical men in need of a masseuse living locally. The register may be obtained from the offices of the society at Tavistock House (North), Tavistock-square, London, W.C., for 4*s*.

Stockport Infirmary.—H.P. £175.

Swansea General and Eye Hospital.—H.P. £150.

Swansea, Swansea and Merthyr, Tydfil, Joint Mental Hospital.—Med. Supt. £800.

Tilbury Hospital, Essex.—H.S. At rate of £150.

Wakefield, Clayton Hospital.—H.S. At rate of £200.

Walsall General Hospital.—H.P. and H.S. Each at rate of £150.

Weir Hospital, Grove-road, Balham, S.W.—Res. M.O. for War Maternity Home. £150.

West London Hospital, Hammersmith-road, W.—Res. Asst. S. £200.

Westminster Hospital, Broad Sanctuary, S.W.—H.S. to Ear, Nose and Throat Dept. At rate of £102.

Weston-super-Mare General Hospital.—Res. H.S. £150.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £150.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.S. At rate of £100.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons at Ripley (Yorks.); Pateley Bridge (Yorks.); Stockport (Ches.); Kirkham (Lancs.).

ADDRESSES AND ORIGINAL ARTICLES

SIMPLE ACHLORHYDRIC ANÆMIA.

BY DANIEL T. DAVIES, M.D., B.SC. WALES,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL.

(From the Middlesex and Royal Free Hospitals.)

IN this article the name simple achlorhydric anæmia, first suggested by Witts,[1] will be used to mean that form of chronic and simple anæmia found in middle-aged women accompanied by achlorhydria. Many other titles have been offered, such as cryptogenetic achylic chloranæmia,[2] pseudo-pernicious anæmia,[3] hypochromatic anæmia,[4] and idiopathic secondary anæmia,[5] but the first title seems to be the most suitable, for it draws attention to the two salient features—a simple anæmia and an achlorhydria—without in any way confusing the condition with pernicious anæmia. Attention was first drawn to it by Faber [6] in 1914, and several papers by continental observers have since emphasised the distinctiveness of the syndrome and its treatment with iron. The credit of rousing English interest in this disorder is due, however, to Witts, who has recorded his studies in recent publications.[1, 7] American work on the subject is seen in the writings of Mills,[5] Watkins,[8] Waugh,[4] and Mettier and Minot.[9]

Although the condition appears to be comparatively common, it has not been widely recognised as a distinct entity. There are many possible reasons for this lack of recognition, among which the chronicity and mildness of the anæmia, the absence of any acute form, and the prominent digestive symptoms may be cited. Indeed the multiplicity of the symptoms complained of, coupled with the listlessness shown by a chronically anæmic woman, is hardly likely to incite clinical enthusiasm. Nevertheless, once the syndrome is recognised as an entity, it is found to be a frequent source of ill-health in women, and one in which therapeutics can materially aid the patient to a return of well-being. In addition, a study of this anæmia throws some further light on the functions of the healthy stomach and its secretion.

The Clinical Picture.

The disease is far more commonly found in women than in men. In Witts' series of 50 cases, 49 were females. In my collection of 55 only four were males. Mills and Waugh also remark on the predominance of the female. In my series the maximum age incidence is between 35 and 50 years—the youngest 30, and the eldest 65. It is therefore a disease of adult womanhood. The duration of the anæmia is usually of many years, five and ten years being common. The additional gastro-intestinal symptoms may also be of equally long duration or even longer. The patient, having suffered from flatulence and pallor for so many years, often fails to fix any date to the first appearance of the symptoms—"having always been pale" and "having always suffered from indigestion."

The symptoms can be divided into two natural groups—those directly due to the anæmia and those due to the digestive disturbances. The symptoms due to the former are in no way different from those of other anæmic states, with the one exception that, as the hæmoglobin is diminished to a much greater extent than the red cells, dyspnœa may become such a prominent symptom as to incapacitate a person from daily work and yet the red cells number above four million. One of the males of the series was a blacksmith, quite incapable of performing his work, although his red cells stood at five million, but his hæmoglobin was only 50 per cent. This state contrasts with that seen in a patient with pernicious anæmia, who is usually at work until the red cells have fallen below three millions.

The alimentary symptoms, although of varying degree, are present almost without exception. Discomfort and fullness after food, a poor appetite, and flatulence are common. These, again, are of long-standing and may dominate the picture for a number of years. The anorexia may be more marked in the morning and improve towards evening. Discomfort is worse after meat and least after carbohydrate foods. In consequence the diet becomes one of bread, potatoes, milk puddings, and tea, the patient being led by her symptoms to believe that other foods are definitely injurious. Many of the patients, when asked, remarked on their loss of desire for any change in diet; they had not touched meat for years, and they were satisfied if they ingested small and frequent carbohydrate feeds.

Symptoms suggestive of visceroptosis can often be elicited from these patients and, indeed, some have resorted to abdominal supports. Diarrhœa was not complained of by any of the observed cases. Although the digestive symptoms are of varying severity they appear to be far more constant than in pernicious anæmia and far more taxing to the patient. They have commenced in such an insidious manner that it is difficult for the patient to give any exact information about their onset.

The appearance of the patient is characteristic in the fully developed case, for the complexion has a peculiar sallowness—almost a lemon tint, as seen in pernicious anæmia—and the sclerotics show a bluish colour; the picture thus does not resemble secondary anæmia from hæmorrhage. The patients are often underweight, and the wrinkles, and folds of inelastic skin contrast with the rotound appearance in pernicious anæmia. Many of my patients were grossly underweight—some only 6 st.—another result of their poor intake of food. The patients often exhibit fissures and painful cracks at the angles of the mouth, and this is accompanied by a well-marked atrophic condition of the tongue mucosa. The more severe the anæmia, the more angry and red does the bald tongue appear, but it is uncommon to obtain complaints of soreness of the tongue. In a few the tongue shows less marked changes, the only observable lesion being atrophy of the papillæ. In this series only five out of 55 showed no tongue changes. The high frequency of a glazed tongue is therefore a valuable diagnostic feature, and more constant in this condition than in pernicious anæmia.

Another characteristic abnormality exhibited by these patients is seen in the nails, which may be unduly brittle, tend to split longitudinally, are commonly flat and sometimes "spoon-shaped"—"koilonychia." Kaznelson [10] drew attention to these nail changes, and emphasised the improvement obtained on adequate treatment. Four of the present series showed the extreme spoon-shaped changes, while 31 complained of excessive brittleness and tenderness, and 26 showed flattening. These nail changes seem to be peculiar to this disease and are not found in pernicious anæmia.

When the anæmia is marked the spleen is often palpable, but not greatly enlarged. With improvement in the anæmia the spleen returns to its normal size. The abdominal wall is atonic and inelastic, and frequently the abdominal aorta can be palpated with undue ease.

The anæmia is more obvious during and after a pregnancy, to improve somewhat later. One of my patients required active treatment during her pregnancies in 1925, 1927, and 1929, but in between the pregnancies, although pale, she was able to do her work. Another gave a similar history during two pregnancies; she improved on their termination, but remained pale. Menstrual irregularities are also recorded; six women complained of amenorrhœa and four of excessive bleeding. So severe was the bleeding in two that radium treatment was contemplated. With the improvement in the anæmia, these patients also showed an improvement in the menstrual cycle. Two of the women gave histories of hæmatemesis, one 23 years previously, and the other 11 years previously, but the majority gave no history of abnormal hæmorrhage, so that the anæmia cannot be accounted for simply by loss of blood.

THE BLOOD.

While there is generally a marked reduction in the hæmoglobin content the red cells are often surprisingly normal. When the hæmoglobin is 40 per cent. or less, it is quite common to find the red cells at four million. The colour-index is therefore much below unity. The average hæmoglobin content of the present series was 52 per cent. and the average red cell count 3·9 million. The lowest hæmoglobin percentage was 25 and the lowest red cell count 2·58 million. No marked abnormality is found in the red cells other than those common to secondary anæmia. Some show a low average diameter, such as 6·9 μ, while others are normal. Witts[1] frequently found microcytosis, but a few patients may show the reverse condition—macrocytosis and a high average red cell diameter. While the majority of my patients showed no abnormal features in the blood films, except those of secondary anæmia, three—two male and one female—showed an average red cell diameter of 7·8 μ and macrocytes. The three were over 55 years of age and are probably examples of the intermediary type between this syndrome and pernicious anæmia.

Some cases show a very minor degree of anæmia; four of this series of 55 showed hæmoglobin values above 70 per cent., although the other features of the disorder were quite manifest on examination. This is of some importance, for it shows that the tongue and nail changes, accompanied as they are by the symptoms of indigestion, may precede the development of anæmia; but the anæmia in such a case may develop rapidly as a result of any aggravating factor —e.g., menorrhagia or pregnancy.

The white cell count in this series varied between 3000 and 7600, counts of 3000–5000 being usual in the more anæmic cases. With improvement in the blood hæmoglobin, the white cells, if previously low, increase to a more normal figure. None of the patients had a leucocytosis.

There is no evidence of increased hæmolysis, for the serum bilirubin is always low and in consequence the serum is pale, a finding which suggested the name "hypochromatic anæmia" in contrast to hyperchromatic or pernicious anæmia.

The blood examination shows, therefore, evidence of a secondary and simple anæmia, the result of hæmoglobin deficiency, which is not due either to blood loss or to excessive hæmolysis, and which is not accompanied by any evidence of a primary marrow disease.

THE GASTRIC SECRETION.

The gastric secretion is of more than usual interest in this condition; indeed the achlorhydria that is commonly found may be, as in pernicious anæmia, the basal and underlying factor in the development of the syndrome. On ordinary fractional analysis, in addition to the absence of free hydrochloric acid, two other features are observed: rapid emptying-rate and increased viscosity of the juice. Emptying-rates of half an hour to one and a half hours are usual, as in all achlorhydric states. Owing to the increased mucus content it is difficult to aspirate the juice. These three findings, the absence of free hydrochloric acid, the increased mucus content, and the rapid emptying-rate, are indicative of a pathological state of the stomach, and are in keeping with the marked symptoms of indigestion.

A clearer understanding of the extent of this deranged secretion is obtained when the juices are examined, before and after the subcutaneous injection of histamine. Of 24 patients of the series who were submitted to the injection of histamine, 12 showed free hydrochloric acid in the samples of juice withdrawn after injection. A further four showed a fall in pH, but not of such a concentration as to be titratable as free hydrochloric acid. In other words, 16 of these 24 patients were not completely incapable of secreting hydrochloric acid, but did so only under stimulation; while eight failed to secrete acid even under stimulation.

Pepsin was demonstrated in 19 out of 25 patients, either in the resting juice or in the samples of juice after histamine injection. In no case was the pepsin secretion found to be as much in health (250–500 units), the average figure being only 70 units. Six showed no pepsin secretion, as well as no acid secretion—true achylia.

A typical result of histamine stimulation is shown in the following figures (Table I.) from a woman aged 44, with a previous achlorhydria on ordinary gastric analysis and exhibiting a mild degree of anæmia (red cells 3·76 million; hæmoglobin 46 per cent.)

TABLE I.

—	Resting juice.	After histamine injection.	
		10 min.	20 min.
Volume	20 c.cm.	15 c.cm.	12 c.cm.
Appearance ..	Cloudy.	Clear.	Clear.
Mucus	+ + +	+ +	+ +
pH	7	7	3
Hydrochloric acid ..	0	0	15
Pepsin	4	64	120

Such a response is obtained in the larger number examined, and presumably is a fair index of the state of the gastric secretion of the majority of the patients. This secretion, with its diminished hydrochloric acid and pepsin content and its excessive mucus, would be consonant with "gastritis."

It is interesting to compare this state of affairs with that seen in pernicious anæmia. In both, an ordinary gastric analysis would disclose an achlorhydria, but, while the achlorhydria in this condition is often only "apparent" or "relative," it is "absolute" in pernicious anæmia even when the patient has returned to health—i.e., the reaction of the stomach juice remains constant. Again, in this syndrome pepsin is still being secreted while there is an absence of pepsin in pernicious anæmia—a true achylia. Finally, mucus, a feature so prominent in the juices of this simple anæmia, is absent in pernicious anæmia.

Examination of the gastric secretion in the syndrome of simple achlorhydric anæmia therefore discloses a marked degree of gastric disturbance, but not of such a severe grade as in pernicious anæmia. The fact that the symptoms are more obvious and distressing is probably accounted for by the fact that the juices are so viscid.

Contributory Factors in Development of the Disorder.

Although the cause of the disease has not been proved, a consideration of the clinical features is highly suggestive of a nutritional disorder. The disease is always chronic, no acute form having been described; it is amenable to iron therapy, and therefore cannot be a primary blood disease; it is not materially influenced by the administration of stomach or liver extract, and therefore the deficiency present in this syndrome cannot be of the same nature as in pernicious anæmia. The two important positive features which may contribute to the genesis of this disorder are the diet and the gastric secretion. The most outstanding feature is the lack of meat ingestion. Many of the patients, on questioning, say that they have not taken any red meat for years, for the obvious reason that they suffer discomfort from meat eating. The same applies to green vegetables. The diet is mainly composed of concentrated starchy foods, of which bread is the chief. Fish is taken without any discomfort. It must be remembered that this diet, poor both in protein and in mineral elements, has been the mainstay of these patients for years. Such a diet is analogous to the diet of tropical countries where anæmia is common.

A similar anæmia produced by feeding polished rice to rats was found by Hart[11] to be as amenable to beef as to liver for re-establishing the hæmoglobin. Bunge,[12] who studied the iron content of the common articles of food, drew attention many years ago to the poor iron content of cereals, and deplored the fact that in the production of fine wheat flour the iron contained in the wheat had been diminished to a fifth of its original value. His emphatic words on the mistakes of treatment adopted for anæmic women in those days are worth quoting: "We may take as an instance the poor bloodless seamstress who eats white bread and drinks tea. With the aid of all our chemical knowledge, we could not give to animals which we wished to make anæmic any food with less iron in it." Milk, rice, and potatoes are all poor in iron, and while red meat contains 17–20 mg. of iron per 100 g. of dried substance, wheat flour contains only 1·6 mg.

Knowing, therefore, that the patients exhibiting this syndrome partake of such a diet for so many years it is justifiable to conclude that their iron intake is poor and liable to result in an iron deficiency. But although a dietetic abnormality is exhibited by the majority, it must be conceded that such an unbalanced diet does not invariably result in an anæmia. On such a restricted diet many patients with a gastric ulcer retain normal blood figures. However, in this syndrome, in addition to the abnormal diet, there is a highly abnormal gastric secretion. It does not appear to be of essential importance to discuss which is the primary condition; it may well be that the gastritis is the initial lesion and the abnormal diet the sequel, but, be this as it may, it seems without doubt that both factors exert an injurious effect, the one on the other.

A recent study by Mettier and Minot[9] sheds important light on the rôle of achlorhydria in this syndrome. Judging the rate of iron absorption by the increase of reticulocytes in the blood stream, they were able to demonstrate that if, after an initial rise due to the ingestion of iron salts, the iron was again given in an acid medium in such a way that the duodenal and jejunal juices were kept acid for a number of hours, a second reticulocyte rise was obtained. From this work it is inferred that the absorption of iron, like that of other minerals, is impaired when there is an absence of free hydrochloric acid, and that a person who shows achlorhydria is susceptible to the development of a simple anæmia which is the result of this lack of iron absorption. They refer to the work of Mitchell and Miller,[13] who found that spinach (rich in iron) was of maximum potency in regenerating the hæmoglobin of the experimental anæmia of dogs when it was given in the form of the acidulated ash. If, in addition to achlorhydria, there is a dietetic deficiency, then two factors are present—a poor intake of iron and a poor absorption of iron.

In this achlorhydric anæmia the diet is deficient in iron and there is a gastritis resulting in absence of hydrochloric acid—two factors with the same end-result—an anæmia which is quickly relieved by the administration of iron.

If a person is severely anæmic as a result of bleeding from a peptic ulcer, there is usually a rapid rise of hæmoglobin and red cells, and seldom is any hæmatinic remedy called for, although the red cells and hæmoglobin may reach a very low level, despite a rigid diet of milk and other foods poor in iron. In these patients the iron stores of the body are probably readily available, and, in addition, the gastric secretion is powerful, resulting in a optimal absorption of the available iron. Those, on the other hand, who are resistant to return to normal levels are either shown to be continuously oozing or are often shown to possess no free hydrochloric acid.

Such a failure to respond was observed in a woman who had a copious hæmatemesis the day before she came under observation. She showed a hæmoglobin percentage of 15 and a red cell count of 2·4 million. Although no further evidence of bleeding was found, the hæmoglobin did not rise above 25 per cent. for nine weeks, and it was only 45 per cent. two weeks later; she showed, however, achlorhydria with excess of mucus, although no organic cause could be found on radiographic examination. This patient had suffered from "gastritis" for years, and had complained of pallor for the previous seven years. Is the delay to return to normal blood values exemplified by this patient related to her gastric deficiency?

The rapid response of the patient following bleeding from an ulcer may therefore be the direct result of his powerful gastric secretion, while that person showing achlorhydria is already at a disadvantage with low and impoverished iron stores through a long-standing deficient absorption of iron from the food.

ANÆMIA AFTER GASTRECTOMY AND GASTRO-ENTEROSTOMY.

The presence of secondary anæmia following gastrectomy and gastro-enterostomy is well known. It appears that the incidence of anæmia in gastrectomy depends on the extent of the gastrectomy, and an interesting paper by Morley[14] has also suggested that the rate of emptying is an important factor in the development of the anæmia; the more quickly the stomach empties the more likely the development of anæmia. He has shown how the Schoemaker operation of gastrectomy, with its longer gastric retention of food, is not usually followed by manifestations of anæmia, while a Polya is frequently followed by a secondary anæmia. In addition to anæmia, typical and advanced atrophic tongue mucosal changes can be seen in patients years after gastro-enterostomy. Gordon Taylor and colleagues[15] noted a similar atrophic mucosa of the tongue following gastrectomy. Since all the manifestations of this syndrome of achlorhydric anæmia can be seen in such surgical cases it appears unnecessary to catalogue them separately; they can be regarded as examples of the complete syndrome in which the operation of gastrectomy or gastro-enterostomy has produced the changes essential to the development of the disorder.

Seven of the present group of 55 were patients who had had a gastro-enterostomy performed many years previously, between 25 and 4 years before the manifestations of anæmia. As is seen from Table II., six showed varying degrees of anæmia, while the seventh (No. 6), although showing typical changes in the tongue and in the nails, still possessed a good hæmoglobin level. The first case showed extreme nail changes, while five complained of brittleness and flatness of the nails. No free hydrochloric was obtainable on ordinary fractional analysis, although one patient did show hydrochloric acid after the injection of histamine. Inquiry into the diet disclosed the same dietetic faults in four of the seven cases, while the remaining three were in the habit of taking some meat daily.

TABLE II.—*Post Gastro-enterostomy Anæmia.*

—	Sex.	Age.	Time of operation (years ago).	Red Cells.	Hæmoglobin per cent.	Tongue	Nails.
1	F.	37	16	3·0	33	Glazed.	Spoon-shaped
2	F.	42	10	4·0	55	,,	Flat and brittle.
3	M.	56	4	3·6	56	Sl. gl.	Nil.
4	F.	52	20	4·6	57	Glazed.	Flat and brittle.
5	F.	42	7	4·2	40	,,	,,
6	F.	56	25	4·9	85	,,	,,
7	F.	45	17	2·8	35	,,	Brittle.

Gastric Juice.—Achlorhydria in each case.
Sl. gl. = Slightly glazed.

The response to iron administration was as good in five of these operated cases as in the "idiopathic" cases. It appears, therefore, that when an operation produces a change in gastric function, such as to result in achlorhydria and rapid emptying, there is a danger of constitutional sequelæ—anæmia, atrophy of the tongue mucosa, and brittleness of the nails. An inadequate diet would accelerate this anæmia, and iron administration would correct it, as well as improving the state of the nails and tongue mucosa.

THE PLUMMER-VINSON SYNDROME.

In considering the cause of this disorder, the syndrome first described by Paterson[16] and Brown Kelly[17] and now called the Plummer-Vinson[18] syndrome, deserves attention. In addition to the dysphagia, there is a long-standing anæmia, atrophy of the tongue, pharyngeal and œsophageal mucosa, a sallow complexion, painful cracks at the angles of the mouth, and changes in the character of the nails. Indeed, the syndrome differs only in the additional dysphagia. Study of the gastric secretion is difficult in this syndrome, but of six examined by R. D. Owen and myself four showed achlorhydria and two showed a secretion of acid after the injection of histamine. Cameron[19] and Witts[1] have also made similar observations; in some cases achlorhydria was found, but it does not seem so common a feature as in simple achlorhydric anæmia.

The laryngologists are inclined to believe that the dysphagia is the primary abnormality, but it appears that atrophic changes are always observed when the patients first complain of dysphagia, although they may state that they have suffered from a "small swallow" for years. In any case, as a result of the dysphagia the diet is a very restricted one of "slops" and very similar to that of the syndrome under discussion.

A typical example showing the course of events is the following, in a woman aged 50, who had suffered from flatulence and discomfort after food for years and who had confined her diet to starchy foods and rarely ate meat, vegetables, or fruit. Her appetite was poor and the bowel constipated. Her swallowing gave rise to occasional difficulties, and necessitated constant caution and much patience but she had not consulted any medical practitioner for this symptom. She had recently experienced palpitations and dyspnœa, for which she sought relief. In addition to the lemon pallor, the lips showed the angular fissures, the tongue showed well-marked atrophic changes, and the nails were flat and brittle. The red cells were 3·7 million, and the hæmoglobin 40 per cent. Achlorhydria was present. As a result of iron administration she felt greatly improved and the blood showed a return almost to normal—red cells 4·6 million and hæmoglobin 80 per cent.

Remarking on the effect of the passage of an œsophageal bougie, Paterson[20] recently stated "Increased ability to swallow immediately follows the passage of a tube, and if this be reinforced by assuring the patient that she is now able to eat solid food, an improvement in the general condition is soon apparent. With the rise in the hæmoglobin content of the blood and the shrinking of the spleen, the relation of the anæmia to the restriction of food is emphasised."

A still closer relationship between these two types of anæmia is exemplified by the following case:—

A woman, aged 42, had enjoyed comparatively good health until seven years ago when, for stomach pains and evidence of an ulcer, a gastro-enterostomy was performed. After the operation digestive symptoms reappeared and the appetite failed. For the last six years the diet has been grossly deficient and anæmia has become apparent. Twelve months ago the tongue mucosa was noted as atrophic; she had frequent cracks at the angles of the mouth, the sclerotics were bluish, and the nails were flat and brittle. The blood showed the usual features: red cells 4·2 million and hæmoglobin 40 per cent. Achlorhydria was present, with hydrochloric acid secreted after histamine.

In other words, the case was typical of simple achlorhydric anæmia. Within the last year dysphagia has appeared and has increased in severity. The condition is now that of the Plummer-Vinson syndrome and the sequence of the gastro-enterostomy, then the anæmia and the atrophy of the mucosa, and lastly the dysphagia, suggests that the primary change in the syndrome is that of the atrophy and that the dysphagia is secondary.

The effect of pregnancy on this simple anæmia is also of some interest. Attention has already been drawn to the exacerbations, the patient obtaining some symptomatic relief with the termination of pregnancy. It is believed that the offspring obtains most if not all of its iron through the placenta, and since the iron content of the liver and other solid organs is high at birth it is reasonable to conclude that pregnancy results in a great depletion of the maternal iron stores, and in consequence an exacerbation of the anæmia in those whose stores are low. Recently Strauss[21] described three cases of this syndrome in women who were pregnant, and in whom the anæmia had become apparent during the pregnancy. In the three the effect of iron therapy was striking.

Metabolism studies on iron in this disorder are lacking, although there is uniformity in the reports of the beneficial effect of iron. As long ago as 1895 Kunkel[22] showed that the liver, spleen, and blood of animals contained an excess of iron after the administration of iron salts with the food. It is now believed that iron, in whichever form it is given, can be demonstrated in increased amounts in such organs as the liver. Recent estimations of the iron in the serum[23] (as distinct from that contained in the hæmoglobin) have shown that, while in pernicious anæmia there is an increase in this value, in some cases of long-standing secondary anæmia as great a decrease is found as in animals rendered anæmic by repeated blood loss. When iron was given to such persons the improvement noted clinically corresponded with an increase in the serum iron. It must, however, be stated that such low values were obtained only seldom, and many cases of secondary anæmia examined by Riecker showed no fall in the serum iron. From these observations he concludes that medicinal iron is seldom required.

The important ætiological features, then, are the deficient diet, poor in iron, the achlorhydria with its impaired absorption of iron, and the simple anæmia with its deficient hæmoglobin and its therapeutic response to iron. All these support the conception of a primary iron deficiency as the essential cause. That such a syndrome develops after gastro-enterostomy (many years after operation) is also in keeping with the hypothesis of an iron deficiency. That a similar picture is also seen in the Plummer-Vinson syndrome further supports the conception of an iron deficiency. I suggest that the first change to occur is the "gastritis," a slow and insidious process, possibly the effect of a blood-borne infection; the result of the "gastritis" is seen in the symptoms of indigestion, and gradually the diet becomes more and more restricted to carbohydrate foods; the iron of the body becomes gradually depleted, and through both factors—a deficient iron intake and a defective iron absorption—this depletion is further enhanced; the production of hæmoglobin fails and anæmia becomes more a prominent feature of the syndrome. When iron is given the anæmia improves.

The Importance of the Disease.

The condition is of importance not only on account of its frequency in middle-aged women, causing a chronic state of anæmia and invalidism, but also because of the widespread nutritional changes that are seen in the fully developed syndrome. Indeed, it appears that the secondary anæmia, the atrophic changes in the tongue mucosa, and the abnormal brittleness of the nails are all manifestations of one and the same deficiency; for not only does the anæmia improve on the administration of iron but, in addition, the tongue mucosa becomes more normal and the nails less brittle and (if previously mal-shaped) grow normally.

The nail changes have only been observed in this disorder and the allied malady, the Plummer-Vinson syndrome. They are not encountered in advanced anæmia and in pernicious anæmia, the nails are always normal to all appearances, so that anæmia *per se* does not materially alter them. But, as has already been suggested, it is highly probable that in both conditions, simple achlorhydric anæmia and Plummer-Vinson syndrome, an iron deficiency is present. Furthermore, since improvement in the character and shape of the nails follows the administration of iron it can be concluded that the bad condition of the nails is intimately related to a long-standing iron deficiency.

Atrophy of the tongue mucosa is seen in many diverse conditions. It is often well marked in pernicious anæmia, subacute combined degeneration of the cord without anæmia, sprue, ulcerative colitis, cœliac rickets, intestinal strictures, and many other alimentary lesions. I have recently observed two cases with repeated intestinal hæmorrhage over a period of three months, and both have developed a glazed tongue while under observation. That the tongue mucosa shows an improvement after liver or stomach extract has been noted by several observers,[24] [25] and Keefer[26] shows photographs of the improvement in cases of anæmia following upon correction of the malnutrition. Similar improvement in the tongue mucosa after iron can be observed in the patients with simple achlorhydric anæmia. Although no actual regeneration of papillæ can be noted, the tongue ceases to be bald and smooth, and becomes less red. The almost constant changes in the tongue in this syndrome and the absence of any history of soreness of the tongue are suggestive of a nutritional disorder, and again may be related to an iron deficiency.

If, therefore, these changes of cutaneous and epithelial structures are nutritional in origin and eventually prove to be an indication of an iron deficiency, then further functions must be attributed to iron in the maintenance of general nutrition.

The relationship between the genesis of this simple anæmia and surgery of the stomach is also of some importance. Such a complication cannot be common, although it probably occurs more frequently than has been realised. That achlorhydria is essential to the development of the syndrome in these operated cases seems also true and, since Lindsay and Evans[27] showed that in a series following gastro-enterostomy only 18 per cent. had persistent achlorhydria, it can be concluded that only a minority possess this disadvantageous state of achlorhydria and therefore become liable to a secondary anæmia. With this achlorhydria, coupled as it is with a rapid emptying, there is a danger of a defective absorption of iron from the food, and when this is further associated with a diet poor in iron, then a chronic anæmia is most likely to develop. It is sometimes difficult to regard the secretion of hydrochloric acid as a valuable asset, when one is confronted with the complications of gastric ulcer, but hydrochloric acid is a normal secretion and, when any mechanism such as gastro-enterostomy results in its suppression, the result may be chronic anæmia.

Relationship to Pernicious Anæmia.

For some years it was thought that the gastric defect played little part in the development of pernicious anæmia, but recent work has shown that the gastric achylia is the real and essential basic lesion. It might be asked, since achlorhydria is found in both types of anæmia, why one person should develop a simple secondary anæmia and another a primary anæmia; for in both the achlorhydria has been in existence for years. There are, however, certain differences.

In the primary type of anæmia the customary history is that the patient, although troubled with a certain degree of flatulence, has been able to digest normal food, and that he has only suffered from anorexia with the advent of the anæmia. Again, examination of the gastric secretion shows the absence of both acid and pepsin; as a result of this atrophic function there is eventually a deficiency in the supply of the necessary factor for the normal maturation of the red cells, with its consequence—a megalocyte anæmia. In spite of the absence of hydrochloric acid, the diet has been so varied throughout the years before the onset of anæmia (Cornell[28]) that adequate absorption of iron has taken place, and, in consequence, although a failure in red-cell production may occur at any time, sufficient iron is available for hæmoglobin production, and the colour-index remains above unity.

This contrasts with the state of affairs in the simple type of anæmia, where the diet has been abnormal for years. The intake of iron has been deficient and, through the absence of hydrochloric acid, the absorption of the little iron present has been defective.

The continued secretion of pepsin and the appearance of acid in some of the patients on stimulation with histamine suggest that the gastric lesion is not of the type which leads to a deficiency, as seen in pernicious anæmia—a deficiency in red-cell production. With the long-standing defective diet and the poor absorption of iron, failure of hæmoglobin production becomes the essential feature, while the red cells are more or less unaffected. That achlorhydria does not of necessity result in an iron deficiency is shown not only by patients with pernicious anæmia (in whom there is always sufficient iron available), but also by more or less normal people who show no anæmia, in spite of achlorhydria. These people generally complain little of indigestion and enjoy a normal diet and, in consequence of this normal diet, presumably are able to ingest sufficient iron for their requirements.

Since both types of anæmia are so intimately related to gastric function, it would not be surprising to meet an intermediate type possessing characteristics of both a primary and also a simple anæmia. Such cases are not common. Six individuals of the present group showed a complete achylia—a secretion identical with that encountered in pernicious anæmia.

A female, aged 48, with a moderate degree of anæmia had 3·9 million red cells and 44 per cent. of hæmoglobin. She showed a good response to iron in spite of the achylia. Time only will prove whether, with such a secretion, the patient will show characteristics of a primary anæmia and will need liver in addition to iron to remain well. It is probable that years must elapse before such a deficiency is made obvious, for it is known that an abnormal gastric secretion has been found 15–20 years before the development of any manifestations of anæmia.

Another who showed achylia was a man aged 58; when first seen in 1929 he showed a severe degree of secondary anæmia—red cells 2·6 million, hæmoglobin 26 per cent. The tongue surface was atrophic, the spleen was palpable, and the nails were normal. As a result of liver extract his blood count rose in nine weeks to: red cells 4·5 million and hæmoglobin 80 per cent. He took no further liver for a period of eight months, when he developed an equally severe grade of secondary anæmia, which again responded to liver extract.

It appears that if an anæmia, although of low colour-index, is characterised by a big reduction in the red cells and also macrocytosis in the blood films, and this be associated with a true achylia, the administration of both liver and iron may produce a better response than either would alone. Such an anæmia is far less common than the ones "true to type."

In Table III. the chief differentiating features between the two types of anæmia are shown.

TABLE III.

	Simple achlorhydric anæmia.	Pernicious anæmia.
Duration of anæmia	Indefinite; 5–10 years or more.	Two years max.
Gastro-intestinal symptoms ..	Usually marked and long-standing.	Not prominent.
Diet	Abnormal for years.	Normal.
Tongue mucosa ..	Atrophic changes constant.	Atrophic changes less frequent.
Nails	Changes common.	None.
Neural signs ..	Uncommon.	Common.
Bilirubinæmia ..	Decreased.	Increased.
Gastric secretion ..	Achlorhydria.	Achylia.
Red cells	Not greatly reduced; microcytes.	Marked reduction; macrocytes.
Hæmoglobin ..	Relatively low.	Relatively high.

Treatment.

"But even if the assimulation of inorganic iron was a proved fact, it would have no importance in medical practice, since, as our experiments show, the iron required for the formation of hæmoglobin is much more readily and plentifully assimilated from the organic iron compounds of our normal dietary. Hence there is in no case any reason to prescribe preparations of iron for the production of hæmoglobin in people who can take their natural food with a good appetite."

Thus did Bunge[39] state his views on the therapeutics of iron in 1889. The further observations of clinical experience have not resulted in any essential alteration in this statement, and, in fact, it is peculiarly apt when this disorder and its response to treatment are considered. For, as has already been emphasised, the food partaken of by these patients is far from being normal or natural, neither do they possess a good appetite. In consequence, if it is agreed that there is an iron deficiency in this disease, material improvement following iron administration should be expected, and upon this there is general agreement, provided iron is given in sufficiently large doses. Satisfactory results have been published by Kaznelson,[10] Meulengracht,[30] Witts,[31] Schulter,[32] and others.

I used ferri et ammon. cit. in doses of grs. 60–90 a day. Provided this is taken over a period of 6 to 12 weeks, there is a decided rise in the hæmoglobin; indeed, the clinical improvement is as striking as that observed in pernicious anæmia with stomach or liver extract. After many years of chronic anæmia the return of a normal hæmoglobin content is accompanied by a well-being which is very new to these invalids.

Of the present series of cases some were only seen once, to obtain treatment elsewhere, some were given additional hæmatinic remedies, others were careless and did not persevere with treatment, while the remainder—those that faithfully ingested the iron as prescribed, over a sufficiently long period—invariably showed a rise in the hæmoglobin as well as a striking improvement in the general health. Table IV. gives the red-cell and hæmoglobin values before and after iron administration in patients who were not given any other form of treatment. An improvement in the hæmoglobin was obtained in all, but as the blood estimations were not done regularly "the duration of treatment" is a somewhat arbitrary figure.

TABLE IV.—*Response to Iron.*

Case.	Initial blood count.		End-result.		Iron Med.†	Case.	Initial blood count.		End-result.		Iron Med.†
	R.C mill.*	Hb. %	R.C. mill.*	Hb. %			R.C. mill.*	Hb. %	R.C. mill.*	Hb. %	
1	3·3	30	5·2	95	2 m.	28	4·6	57	5·0	95	2 m.
3	4·05	55	5·0	96	2½ m.	29	4·3	46	5·2	82	3 m.
4	5·0	52	5·75	85	6 w.	30	3·8	25	4·8	84	3 m.
5	4·8	48	5·0	98	3 m.	31	3·7	40	4·6	80	3 m.
17	2·8	35	4·9	75	3¼ m.	32	4·7	53	5·0	92	2¼ m.
18	3·8	48	5·2	86	2½ m.	33	2·4	40	4·0	85	2¼ m.
20	4·6	65	4·8	110	2¼ m.	34	4·3	30	4·5	82	4 m.
21	3·76	46	5·4	70	6 w.	35	4·7	38	4·8	84	3 m.
23	2·5	25	4·6	75	3 m.	36	2·5	22	4·5	70	5 m.
26	4·1	42	4·9	85	2½ m.	52	3·1	34	4·3	78	3 m.

* R.C. mill. = red cells in millions. M. = months; w. = weeks.
† Iron med. = duration of iron medication.

No untoward symptoms have been noted as a result of the ingestion of these large doses of iron, and only one patient was unable to tolerate grs. 25 three times a day. It is not known why such large doses are necessary, and little is known of the fate of the iron that is absorbed, other than its storage in the liver. It is necessary to continue with smaller doses of iron to prevent relapse, as was shown by some of this series in whom the hæmoglobin fell to its original level of 40 per cent. or so in six months on the cessation of iron therapy. When once the hæmoglobin has reached the 95–100 per cent. level the dose was reduced to gr. 10 three times a day.

In addition to the improvement in the anæmia, the nails and tongue changes become less marked, and in some patients the original departures from normal have completely disappeared, although no actual regeneration of papillæ has been observed in the tongue mucosa. Furthermore, some patients show a gain in weight following general improvement; one patient increased in weight from 6 st. 8 lb. to 7 st. 8½ lb. in nine weeks.

It is a question whether iron should be prescribed to the individuals who show achlorhydria, atrophic changes in the tongue, and undue brittleness of the nails without any marked reduction in hæmoglobin. Several such patients have been given iron and, although exact proof of benefit is difficult to record when the hæmoglobin is already above 80 per cent., yet the return of well-being and vigour has been sufficiently marked to warrant iron administration even in these cases.

The treatment of the digestive disturbances is a more difficult project. It is probable that the anæmia would gradually disappear if the gastric secretion could be re-established, and, as a result of this, appetite and hunger for meat and other articles rich in iron could return to the patient. To attain this, washing out the stomach, to free it of its thick coat of mucus, would be a direct benefit, as Hurst[33] has emphasised. Two patients, previously showing achlorhydria on ordinary fractional analysis, showed a return of acid on a similar examination three and four weeks after daily lavage of the stomach; but as the rise in hæmoglobin was too slow, and domestic reasons forbade delay, these patients were later given iron in addition. Keefer[34] has recently shown that an improvement in an existing anæmia results in a better gastric secretion, and that some of his cases of malnutrition anæmia (tropical in origin), previously showing achlorhydria, showed a return of free acid when their anæmia was corrected. He concludes that achlorhydria is often the result of the anæmia. Whilst it must be readily admitted that such improvement is conceivable and natural, it would be difficult to regard the anæmia in this syndrome as the causative factor in the development of achlorhydria, for several patients with little anæmia yet show achlorhydria, and all the factors point to the gastric abnormality as the primary change. Six of the patients who showed a good response to iron alone were re-examined after they had returned to normal figures, but no improvement was noted in the gastric secretion.

The administration of hydrochloric acid has been frequently tried and applauded, but it is extremely difficult to subsidise the natural secretion. Many years ago Zander[35] claimed that hydrochloric acid administered to a patient with chlorosis was of more lasting benefit than iron, for, in his opinion, it caused a better absorption of iron from the food. Stockman[36] and others failed to confirm these observations in chlorosis. The position is much the same to-day, and the concensus of opinion seems to be that hydrochloric acid administered to a patient with achlorhydria cannot be of much therapeutic importance except in post-prandial diarrhœa. However, there are some patients in whom flatulence and discomfort after food is especially relieved by either hydrochloric acid alone or a mixture containing hydrochloric acid and pepsin. I have frequently obtained symptomatic benefit in this type of patient from a mixture containing a drachm of hydrochloric acid and a drachm of glycerin of pepsin, made up with orange or lemon water, taken after or during meals. Some patients seem to derive no benefit from hydrochloric acid; in fact it appears to increase the discomfort. Others find relief from a morning dose of alkali powder taken half an hour before breakfast; this probably acts by removing the thick coat of mucus and allowing a better gastric secretion during the meal.

Conclusion.

Simple achlorhydric anæmia appears to be a common and chronic anæmia of adult womanhood. The evidence available is suggestive of an iron deficiency, consequent on a defective diet, and an impaired gastric secretion. The disorder can be therapeutically corrected by the administration of iron, but this does not remove the cause. Attention to the gastric secretion and measures to improve it should ultimately result in a better intake and a better absorption of iron. The disease is worthy of attention, not only on account of its frequency in women and the ease of its correction from the standpoint of the anæmia, but also on account of its appearance in patients who have undergone surgical treatment to the stomach. Its development is a further index of the normal function of hydrochloric acid secretion. In addition, it is possible that the malnutritional changes, such as those in the tongue mucosa and entrance to the food passage and in the nails, are related to a long-standing deficiency of iron.

It is a pleasure to acknowledge the kindness of the honorary physicians of the Middlesex and Royal Free Hospitals in allowing free access to the patients under their care.

CONGENITAL ELEVATION OF THE DIAPHRAGM,

WITH REPORTS ON SIX CASES.

By W. Burton Wood, M.D., M.R.C.P.Lond.,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK;

AND

Franklin G. Wood, M.B., D.M.R.E. Camb.,
ASSISTANT RADIOLOGIST TO THE GERMAN HOSPITAL, DALSTON; AND TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS.

Congenital elevation of the diaphragm is a condition due to faulty development of this organ, as the result of which the diaphragmatic dome on one side, usually the left, forms a sac bulging upwards into the thorax and containing displaced abdominal viscera.

The condition was first recognised and described by Jean Louis Petit (1674–1750), who gave it the name of *eventratio diaphragmatica*. His collected writings, however, were not printed until nearly a quarter of a century after his death, when his pupil, Lesne, published them as a memorial of a master greatly beloved.[1] It is thus to Lesne that we owe the preservation of Petit's account of the first known case. If medical precedent had been followed and the condition were known as Petit's disease, fitting tribute would have been paid to one whose name should not be allowed to pass into oblivion.

After describing diaphragmatic hernia, Petit records another example of diaphragmatic displacement which, in his opinion, must have been due to an error in development. The patient had suffered for long from attacks of asthma, aggravated by eating, and had died after an attack of "inflammation of the stomach." At autopsy Petit discovered that the left side of the diaphragm projected upwards into the thorax, forming a large sac. The base of the left lung was glued to this by adhesions, while, on opening the belly, the sac was found to contain the stomach, colon, and mesentery, matted together as the result of recent inflammation. The diaphragm was intact, and Petit lays stress on the fact that there was no rupture in its vault nor any separation of its muscular or tendinous fibres. The case thus differed from cases previously described, in which he had noted a true hernia of the diaphragm.

Cases were subsequently recorded by Froriep[2] (1837), Lawrence[3] (1852), Howard Marsh[4] (1867), Thoma[5] (1882), Tennant[6] (1894), Kronig[7] (1898), and others in succeeding years. It is to Woodburn Morison, however, that we owe the first complete account of the condition, and his admirable monograph[8] on the subject has already taken its place among the classics of medical literature. Each of the cases of diaphragmatic eventration referred to above was discovered at autopsy, and the descriptions refer to appearances found post mortem.

The first instance of the application of X rays to the diagnosis of diaphragmatic eventration that we have been able to discover in medical literature was made in 1901 by Widenmann.[9] The patient, a man aged 48 years, who had suffered from repeated attacks of pain in the chest, was X rayed. The skiagram revealed a dome-shaped shadow projecting upwards into the left side of the thorax. Proof that this shadow was cast by the diaphragm, and that the stomach lay immediately beneath it, was forthcoming when a sound of zinc and small shot was passed into the stomach by way of the œsophagus, and could be seen curling upwards in the clear area immediately below the diaphragmatic arc.

A further application of modern diagnostic methods to the examination of the malformation was made by Baetge (1913),[10] who utilised the electro cardiogram. He claimed that the tracings showed a departure from the normal owing to the displacement of the heart to the right. We have, however, been unable to confirm this, for electro cardiograms of two of our cases, kindly taken by Dr. A. J. Scott Pinchin, showed that the wave forms were not abnormal.

A still more ingenious method of differentiating between gastric hernia and eventration was successfully employed by Hildebrand and Hess.[11] A tube passed into the stomach communicated with a manometer which enabled the intra-gastric pressure to be estimated during the two respiratory phases. Obviously, if the stomach is in the abdominal cavity, intra-gastric pressure will rise during inspiration and fall during expiration, but if the stomach is situated in the thoracic cavity—i.e., if there is hernia of the diaphragm, the reverse effect will be noted.

Ætiology.

The diaphragm is raised in many pathological conditions: (1) Certain abdominal conditions—e.g., ascites, pregnancy, subphrenic abscess. (2) Pulmonary diseases—e.g., tuberculosis, especially of the fibroid type, fibroid lung, atelectasis, neoplasm. (3) Paralysis of the phrenic nerve due to disease, trauma, or operation. (4) Temporary elevation of doubtful origin may occur in children or in adults as the result of trauma. An example of the latter is shown by the following case:

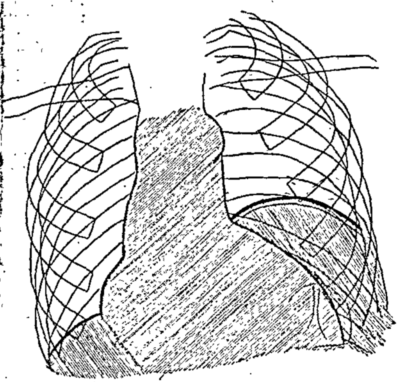
A man, aged 58, whilst working, hit the left side of his chest against an iron grating. Considerable bruising and swelling resulted, and a fracture of the lower ribs was suspected. An X ray photograph was taken but no fracture was seen. On the other hand, the left dome of the diaphragm was found to be raised to the level of about the ninth rib behind. Two months later a second film was taken. In this radiogram both domes of the diaphragm were at the usual level. All pain and swelling had disappeared and the patient stated that he was quite well. The elevation of the left dome of the diaphragm in this case thus appears to be related to the injury to the chest wall, and might be explained as a reflex phenomenon designed to prevent the pain that would have resulted from a contraction of the diaphragm on the injured side.

In all these cases the cause of the rise in the diaphragm is obvious. It is characteristic of eventration that a considerable degree of elevation is present in the absence of any demonstrable cause. There is no increase in intra-abdominal pressure, there is no disease of the lungs, and in at least one case in which a microscopical examination of the phrenic nerve was made after death, the sections showed no abnormality,[12] and though, in another case, Benda found reduction in the size of a phrenic nerve, the fibres were normal.

There seems, indeed, no reason to doubt that Petit was correct in regarding the condition as a congenital defect, for it has been found at the autopsy on a child who only lived 24 hours, and even in a fœtus. It is worthy of note, also, that in nine of the reported cases elevation of the diaphragm was accompanied by other congenital abnormalities.

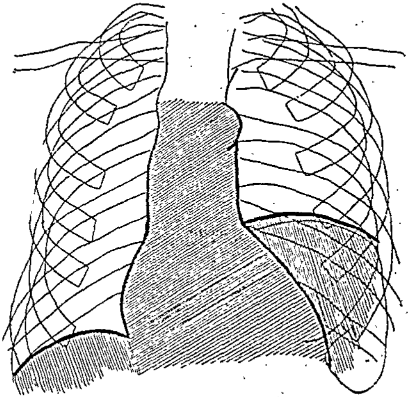
If eventration of the diaphragm is a congenital condition the development of the diaphragm is worthy of consideration. The pericardial, pleural, and peritoneal cavities of the adult are formed by subdivisions of the embryonic body cavity. The anterior end of the cœlom containing the heart is shut off by a partition which forms at about the sixth week of intra-uterine life and, at a slightly later date, the two pleural sacs are separated from the peritoneal cavity by the completion of the diaphragm. The greater part of the latter is formed from the septum transversum, which is ventral in situation, while the dorsolateral portions are derived from the pleuro-peritoneal membranes which close the communicating ducts between the two cavities on the right and left sides. The musculature of the diaphragm is stated to be developed from two muscle masses, derived from the fourth cervical myotome.[13] These grow into the developing diaphragm while the septum transversum is still in the cervical region. Later the diaphragm migrates caudally to reach its proper place.

FIG. 1 (Case 3).



A drawing of a film taken in expiration to contrast with one in inspiration. The right dome of the diaphragm is at the level of the upper margin of the anterior extremity *of the* fifth rib, and the left dome at the level of the anterior extremity of the third rib.

FIG. 2 (Case 3).



A drawing of a film of Case 3 taken in inspiration. The right dome of the diaphragm is now opposite the anterior extremity of the sixth rib, whilst the left dome, which is flatter than in the previous film, has moved down to the anterior extremity of the fourth rib. A definite contraction of the left dome of the diaphragm has thus occurred.

In congenital elevation the right side of the diaphragm is in its normal position, whilst the left cupola forms a thin sac with normal attachments, but projecting into the thorax to reach a high level. It seems, probable, therefore, that neither a failure of migration nor a failure of union of the component parts (a cause of hernia of the diaphragm) is responsible for the condition, but a failure of the development of the musculature on one side. As a result of this, the muscle sheet is almost entirely replaced by a thin membrane, which yields to abdominal pressure. Such a sequence might be expected, for the pressure in the pleural is lower than that in the abdominal cavity, and a membranous diaphragm would fail to fulfil its pressor function.

Clinical Aspect.

The malformation is generally discovered by chance in the living as the result of radiological examination or operation, or in the dead at autopsy. There are no distinctive symptoms, though dyspnœa and dyspepsia have often been noted.

The time-honoured methods of inspection, palpation, auscultation, and percussion, though we cannot afford to dispense with them, have only a limited value in the investigation of obscure disease of the chest. The excellent quality of modern radiograms of the thorax has compelled even the conservative to admit that a skiagram forms an essential part of a complete examination of the chest. In the opinion of the more progressive, an X ray examination is the essential part. It is true that a good physical examination is better than a poor skiagram, but a good skiagram furnishes more reliable information than that obtained by any other method. The application of the classical method of physical examination in one of our cases (Case 1) led to an entirely erroneous conclusion. The patient complained of dyspnœa, there was a family history of tuberculosis, the percussion note was impaired at the base of the left lung, vocal fremitus could not be felt, and vocal resonance was inaudible over the dull area. There was also displacement of the heart away from the affected side. A tentative diagnosis of tuberculous pleural effusion seemed justified. A skiagram demonstrated an elevation of the diaphragm, and a single glance at the film disclosed more than a careful clinical examination had been able to discover. The quickest method of revealing the secrets of the thorax, like those of Joanna Southcote's box, is the intelligent application of the X rays. A brief description of the physical signs will therefore suffice.

On inspection there may be diminished movement of the affected side of the chest—almost always the *left side*. The presence of Litten's sign has been noted. On palpation vocal fremitus is reduced at the left base. The results of percussion will depend upon the relative amounts of fluid and air in the stomach, a dull note being elicited over fluid and a tympanitic note over the inflated part of the organ. Tympany may extend as high as the fourth rib anteriorly. On auscultation breath sounds and vocal resonance are absent over an area approximately corresponding with the height of the diaphragm. A succussion splash is usually evident, for the stomach is rarely empty.

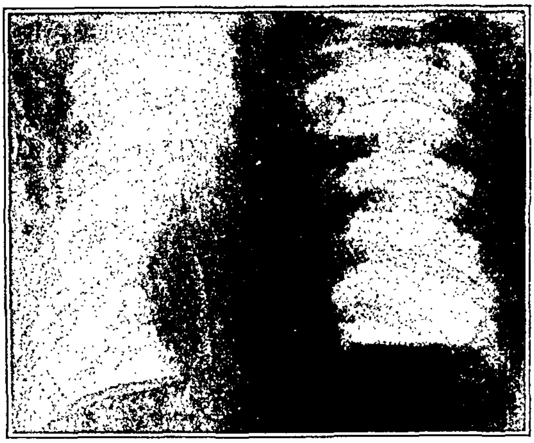
RADIOLOGICAL EXAMINATION.

The following descriptions refer to left-sided eventration.

Fluoroscopy shows the diaphragmatic movement.

During quiet respiration the unaffected dome exhibits normal excursions. These are usually well marked, but there is no evidence of exaggeration to compensate for the absence of movement on the elevated side.

FIG. 3 (Case 1).

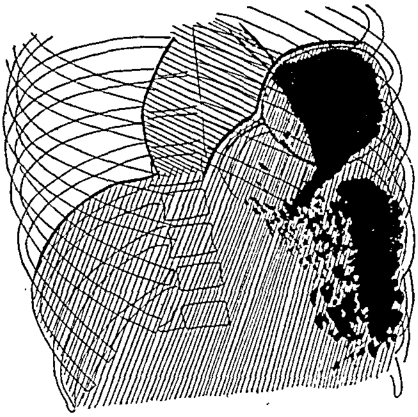


An erect anterior view taken after an ordinary meal without barium. The raised bowline of the left dome of the diaphragm and displacement of the heart to the right are shown. In addition three fluid levels are seen in the stomach, disposed one above the other.

When the patient is instructed to breathe deeply, the abnormally elevated dome will be seen to move slightly up and down, its excursions being synchronous with those of the healthy side. Only one of our cases (No. 5) showed a contrary or paradoxical movement, such as is seen in paralysis of the diaphragm. In Case 3 true contraction of the diaphragm was proved by radiograms taken in inspiration and expiration (Figs. 1 and 2).

A *radiogram* taken when the patient is recumbent shows the right side of the diaphragm in its normal situation while the left side exhibits a boldly outlined and smoothly rounded dome, the summit of which may be at the level of the second or third intercostal space. No stomach bubble can be made out in this position, but the splenic flexure, with its contained gas, is seen lying high up under the raised diaphragm. The heart's shadow is displaced to the right, and just above it the translucency of the bifurcation of the trachea is similarly displaced. Below the affected diaphragm a uniform opacity obscures the view, except in those cases in which, as noted above, some evidence of a displaced splenic flexure is found.

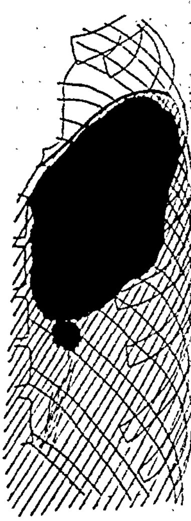
FIG. 5 (Case 6).



A drawing of a film taken prone ten minutes after the ingestion of a barium meal. The patient is rotated slightly into the right oblique position. The left dome of the diaphragm does not form an uninterrupted bowline as seen in the anterior view, but presents a bulge where the fundus of the stomach presses on the diaphragm. Barium is seen in the stomach and some barium has passed out into the smaller intestine.

When a radiogram of the patient in the erect posture is taken a very characteristic picture is obtained (Fig. 3). Where previously an opacity was observed in the left lower zone a large gastric air-bubble is now revealed above which arches the bow line of the diaphragm. The contour of this line is unbroken in antero-posterior and lateral views, but an oblique view may show a bulge (with convexity upwards) where the gastric fundus presses against the concavity of the thin and yielding diaphragm (See Fig. 2). Below the area of translucency, especially if the patient has recently enjoyed a good meal, can be seen two or more typically three-fluid levels in the stomach. If the surfaces of the fluid levels be traced to the left they will be seen to merge into the shadowy outlines of the splenic flexure with its usual gaseous content.

FIG. 4 (Case 6).

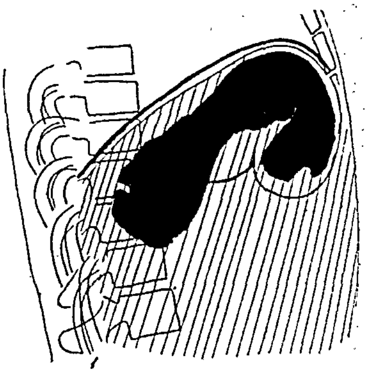


A drawing of a film taken in the prone position five minutes after the administration of a barium meal. The fundus of the stomach lies high up under the raised left dome of the diaphragm. The duodenal bulb is outlined by barium and points directly downwards. The second and third parts form a straight line instead of the usual loop.

In the erect lateral position the three fluid levels corresponding to those seen in the antero-posterior position may also be seen, but whereas in the antero-posterior position they are placed more or less vertically above each other, in the lateral position they exhibit a staircase formation, the stairs ascending from left to right.

Further information and confirmation of diagnosis can be obtained by examination after a barium meal. If the patient attends fasting, unless he is an air-swallower, the appearances mentioned above will not be well seen, for the gastric air bubble will be inconspicuous and the fluid levels indistinct or absent.

FIG. 6 (Case 6).



Drawing of a lateral prone view taken after ingestion of barium. The greater curvature of the stomach is displaced upwards, and together with the fundus follows the line of the raised diaphragm in a postero-anterior direction. The shape of the stomach has a resemblance to a bagpipe.

Barium meal examination.—The patient is placed behind the screen and rotated into the right oblique position. The barium is now administered and its progress down the œsophagus is watched. The cardiac orifice appears to be low in position in relation to the rest of the stomach. As the result of

FIG. 7 (Case 4).

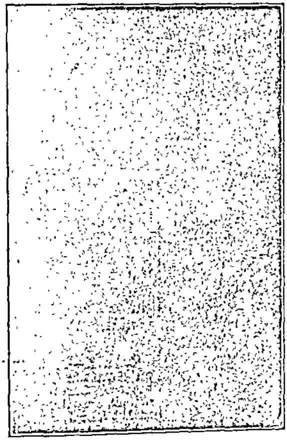


FIG. 8 (Case 4).

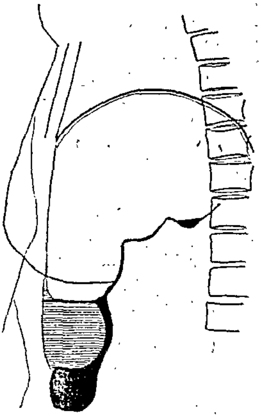

Fig. 7 is a lateral erect view of Case 4, taken immediately after some barium emulsion had been swallowed. *The barium can be seen* running down the posterior wall of the stomach and outlining three folds: (1) an upper posterior one which contains a small pool of barium, (2) a middle smaller fold, and (3) an anterior fold which runs down into the main *body of the* stomach, where there is a large fluid level.

Fig. 8 is an outline drawing of the barium meal appearances seen in Fig. 7. Compare with Fig. 10, where the arrangement was more complex.

this, the fluid on entering the stomach appears to pass upwards towards the fundus and then to pass downwards towards the pyloric end. The whole of the stomach is seen to be situated more to the eft than usual, whilst the duodenum is also displaced to he left with its bulb pointing ransversely to the right, or downwards towards the pelvis Fig. 4). It is thus obvious hat the shape and position f the stomach are abnormal. Examination with the patient ying on the back is necessary f diaphragmatic hernia is to e excluded. In this position he smooth contours of the undus are outlined by barium, nd it will be noted that none f the barium lies above the iaphragmatic level. In cases f hernia, recumbency will ause some of the barium to ass into a pouch above the iaphragm.

The appearances are equally bnormal in the lateral view. A picture taken with the patient ying down shows the smooth, urved contour of the raised ome of the diaphragm and mmediately beneath it the tomach, which is distorted so as to resemble a bagpipe n shape (Figs. 5 and 6).

We were doubtful of the correct interpretation of he three fluid levels seen in the antero-posterior nd lateral erect views until we were so fortunate as o secure a radiogram from the lateral aspect mmediately after the patient had swallowed some arium. When the picture was taken a film of arium was still adherent to the gastric mucous membrane and the *posterior* wall of the stomach was clearly delineated. A curious folding of the walls was seen *to* be responsible *for* three little pools of barium: an upper one near the œsophageal opening, a smaller one just in front of this, and a larger one more anteriorly placed, the walls of which seemed to be formed by the main body of the stomach. The lateral view thus presented the appearance of a cascade with a stream of barium connecting the three pools (Figs. 7 and 8). In Case 3 an even more complex appearance was shown in the anterior and lateral

FIG. 9 (Case 3).

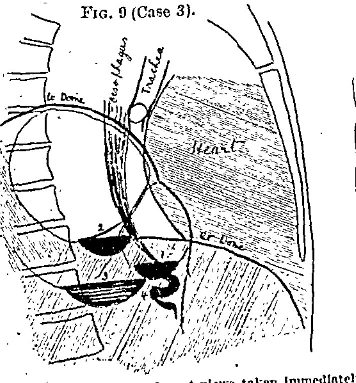

FIG. 10 (Case 3).

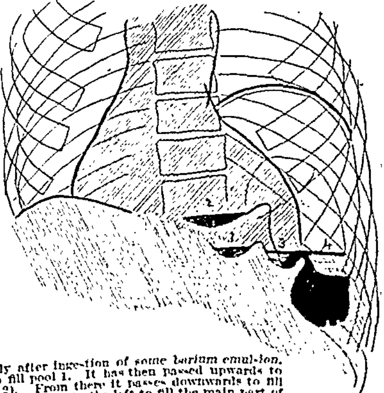


Drawings of anterior and lateral erect views taken immediately after ingestion of some *barium emulsion.* The barium can be seen running down in the œsophagus to fill pool 1. It has then passed upwards to fill a pool situated higher up and more posteriorly (pool 2). From there it passes downwards to fill pool 3, and from here a stream of barium is seen passing forwards and *to the left* to fill the main part of the stomach, which is situated at level 4. Four distinct fluid levels are thus present.

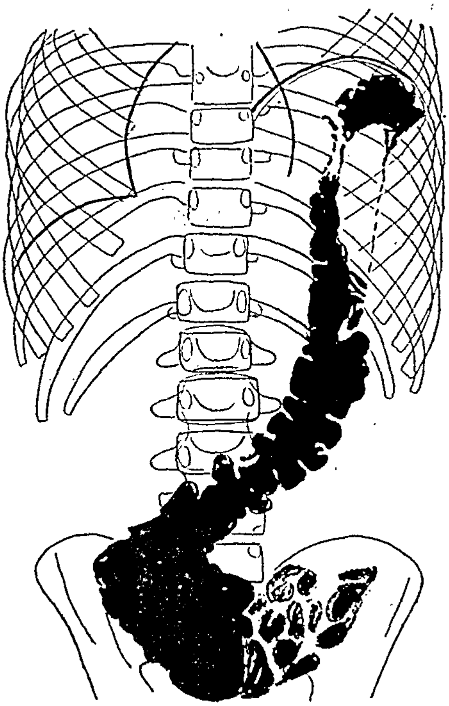
erect views, the barium outlining four possible fluid levels (Figs. 9 and 10).

If the meal is followed until it reaches the large bowel, the cæcum will probably be found in the pelvis, the hepatic flexure low in position, and the transverse colon running upwards to the left in an oblique line to meet the splenic flexure high under the raised dome of the diaphragm (Fig. 11).

Post-mortem Appearances.

Though six patients affected by eventration have attended our clinic, we have had no opportunity of comparing the results of physical and radiological examination with post-mortem findings. We have therefore had to rely on the descriptions of others when trying to visualise the pathological condition. The reported cases agree in their accounts of the displacement of abdominal organs and the appearance of the undeveloped and raised hemi-diaphragm. Petit describes the wall of the "sac" as formed of peritoneum, diaphragm, and pleura united by adhesions. He emphasises the absence of any rupture of the wall of the sac and also draws special attention to the fact that there was "no separation of the muscular and tendinous fibres of the diaphragm." Lawrence, who discovered eventration at the autopsy on a patient who had died of pneumonia, found that the muscular tissue only extended from the inner surface of the ribs and arcuate ligaments for a distance of 6–8 lines, and noted that such fibres as were present were only perceptible by transmitted light. The remainder of the left half of the diaphragm consisted of an aponeurotic expansion merging into the central tendon. An example of a partial atrophy is supplied by Tennant, who found eventration of the diaphragm in a dissecting-room subject. The elevated diaphragm formed a pouch extending to the height of the second costal cartilage. The anterior half of the left side of the diaphragm was normal, but posteriorly it was thin and translucent. Only a few scattered muscular fibres could be found in the affected area.

FIG. 11 (Case 6).



A film taken when lying down six hours after the ingestion of the barium meal. The large bowel is filled as far as the splenic flexure. A residue of barium is still present in the small intestine. The cæcum is situated at the brim of the pelvis, whilst the hepatic flexure is at the level of the right iliac crest. The transverse colon runs obliquely upwards and to the left towards the splenic flexure, which is very high in position. The hepatic flexure is thus abnormally low. (This was seen also in one of the other cases.)

Treatment.

No curative treatment is possible. Fortunately the condition seldom causes discomfort. Symptomatic treatment for any gastric disorders, should these arise, is obviously indicated. For the rest, the patient may be reassured that his abnormality is unlikely either to lessen his efficiency or to shorten his life. He enjoys the gratification of being an interesting case whose appearance at hospital will always excite a lively concern, and he suffers few of the disabilities commonly attaching to such a condition.

Case Reports.

CASE 1.—A warehouse boy, aged 16, attended hospital on Nov. 23rd, 1926, complaining of chronic shortness of breath. One week before attendance he had had a feverish attack, associated with vomiting. He had had diphtheria in 1922, and his sister had died of tuberculous meningitis.

There was impaired percussion note on the left base posteriorly, and the breath sounds, vocal resonance, and vocal fremitus were absent. The heart was slightly displaced to the right. A succussion splash was elicited at a later visit. X ray examination showed typical congenital elevation of the left side of the diaphragm.

CASE 2.—A motor driver, aged 50, attended hospital on Nov. 18th, 1930, complaining of morning cough and retching of 12 years' duration, also dyspnœa of three years' standing. Apart from these he had enjoyed good health.

There was impaired percussion note and weak breath sounds with some coarse râles at the left base posteriorly, and elsewhere signs of emphysema. The heart was slightly displaced to the right. The liver was enlarged, ? cirrhotic. The electrocardiogram showed physiological rhythm and left side relative preponderance, and the skiagram a typical left-sided elevation of the diaphragm.

CASE 3.—A retired motor driver, aged 68, attended hospital on Jan. 27th, 1931. He had been a district railway motor driver for 45 years without losing a day through ill-health till Nov. 24th, 1930, when he was admitted to the West London Hospital suffering from intestinal obstruction. At operation performed for the relief of this six or seven days later it was noticed that the left side of the diaphragm was at an abnormally high level. The patient made an uneventful recovery and went home in 23 days from admission. The X ray showed typical left-sided elevation of the diaphragm.

CASE 4.—A dressmaker, aged 21, attended hospital on Nov. 11th, 1930. The patient had previously attended Leyton Tuberculosis Dispensary as a "suspect" complaining of four weeks' cough. Her father had died of phthisis in 1919.

Breath sounds were absent at the left base posteriorly, the percussion note in the same area being of slightly higher pitch than normal. The breath sounds in the left axilla were weak. X ray examination showed a typical left-sided eventration.

CASE 5.— A piano-worker, aged 30, attended hospital on Nov. 11th, 1930, complaining of a cough which had led his doctor to suspect pulmonary tuberculosis. He had had double pneumonia in 1921, and been bed-ridden for five weeks.

The breath sounds were weak over the upper half of the right lung and absent below the angle of the scapula. No impaired resonance or alteration of vocal fremitus or resonance was found. The liver dullness extended from the fifth intercostal space to the costal margin. The skiagram showed that the right dome of the diaphragm was raised to the fifth intercostal space in the nipple line, the left dome being at the normal level; some faint mottling suggested that tuberculous foci were seen in the left mid-zone. The right costophrenic angle was obliterated. On screen examination paradoxical movement of the diaphragm was seen, a phenomenon not observed in any of our left-sided elevations.

CASE 6.—A boy, aged 12, attended hospital on Jan. 23rd, 1930, complaining of occasional "retching" not related to meals and associated with slight pain in the upper part of the left side of the "stomach." In March, 1928, he had been thrown out of a cart into a field on his stomach and admitted to Woodford Hospital for suspected abdominal injury; he had remained in hospital two weeks. He subsequently complained of pains in the left side of the chest and retching at times, but there was no vomiting. He had had similar attacks three or four times a week up to his attendance at hospital.

The patient was a poorly nourished boy, of small size for his age. There was impairment of percussion note at the base of the left lung, extending from the angle of the scapula to the base, and also in the left axillary region and anteriorly below the level of the fourth rib. Breath sounds, vocal fremitus, and vocal resonance were absent in this area. No succussion splash was heard on shaking the patient. A skiagram showed a typical left-sided elevation of the diaphragm.

H. G. Wells has suggested that the discovery of the secret of cancer will be made, not by a philanthropist burning with zeal to relieve the sufferings of his fellows, but by a laboratory worker consumed with an eager curiosity that has no direct connexion with humanitarian motives. The condition we have been considering may at first sight seem to be one of small practical importance. The subjects of this curious deformity are few, their sufferings are negligible; we can do nothing to restore a normal balance to the organism. But the curiosities of medical practice have their value if they stimulate the inquiring attitude of mind, and the study of even the rarest abnormalities of development may ultimately assist us to a knowledge of how to prevent the congenital deformities which in their graver manifestations are the cause of serious disability or even acute suffering.

Our thanks are due to Dr. A. J. Scott Pinchin, Dr. K. Shirley Smith, Dr. T. L. Ormerod, and Dr. H. T. Howell, who kindly allowed us to make use of their cases, and also to Dr. J. V. Sparks for helpful assistance and advice.

GLOSSO-PHARYNGEAL NEURALGIA.

By Geoffrey Jefferson, M.S. Lond., F.R.C.S. Eng.,
HON. SURGEON TO SALFORD ROYAL HOSPITAL; AND HON.
NEUROLOGICAL SURGEON TO THE MANCHESTER
ROYAL INFIRMARY.

It has for some years been known that it is possible for a patient to suffer from paroxysmal pain in the distribution of the glosso-pharyngeal nerve. Neuralgia of this nerve is in all respects the counterpart of the much commoner neuralgia of the trigeminus, presenting the same intermissions and remissions, the same brief excrutiating pains, the same precipitation of spasms by specific movements or contacts. The difference, clinically, between trigeminal and glosso-pharyngeal neuralgia lies purely in the territory in which the pain is experienced, on the one hand in the face, on the other in the throat and ear, but especially in the throat.

Weisenberg (1910), in the course of an excellent account of a lateral recess tumour in a man of 35, for the first time drew attention to the painful syndrome of the glosso-pharyngeal nerve.

In his case the pain was produced by the pressure of a tumour on the nerve, the irritative phenomena being as follows: "(the pains) were chiefly localised to the back of the tongue, or, as he expressed it, at the 'root,' and ran down the throat to his ear. He always complained of a burning feeling in his throat, and occasionally of sensations which he likened to the crawling of roaches or flies, of a constant dryness, and of a feeling like hot or ice-cold water. He had, besides, sharp, shooting, stinging pains, which started in the back of the right side of the tongue and ran to the right ear and down the right side of the throat and, when they were exceptionally severe, to the shoulder. These lasted only for a few minutes, were sometimes agonising, and nearly always caused him to turn his head and neck to the right. Eating, especially in the last year of his illness, would always cause him pain, and his wife does not remember a single meal that he ate during this time in which he did not have attacks of pain. He did not have difficulty in swallowing, and he never choked. The pains while eating were brought on not so much by the chewing as by the contact of the food with the posterior part of his mouth and by swallowing."

Weisenberg, in critical discussion of his own case, does not specifically state that spontaneous neuralgia might originate in the glosso-pharyngeal nerve. Wilfred Harris (1921) was the first to bring forward examples of this new clinical entity, the first, that is, if we set aside, as seems proper, three cases of pharyngeal neuralgia recorded by Sicard and Robineau (1920) on the ground that these authors were not certain whether the pain originated in glosso-pharyngeus, vagus, or cervical sympathetic. Further records appeared in the American literature, notably those by Doyle (1923), Adson (1924), Singleton (1926), Dandy (1927), and Stookey (1928). Purdon Martin's (1931) paper describing a case, and discussing generally the features of the disease, if we may so term a neuralgia, is the most recent addition.

The pain of spontaneous glosso-pharyngeal neuralgia is very similar to the secondary pain described by Weisenberg. It generally strikes into the throat, and particularly at the junction of the faucial pillars with the base of the tongue, and a "trigger zone" has been noted at this point in some cases. The pain shoots from the lateral wall of the pharynx into the ear, particularly on swallowing, and it has generally first appeared during that act.

The case to be described is, so far, unique not because the pain began in the ear (for this has been noted before), but because it remained there for over 30 years before it spread to the throat.

Case Record.

A. B., a Jew aged 70, was admitted to the Salford Royal Hospital on Oct. 20th, 1929, complaining of paroxysmal pain deep in the left ear. The history of the malady extended back over a period of 36 years, with long remissions; apart from this his health had been, and still remained, excellent.

He was accustomed to have two attacks of pain each year, but latterly it had returned with great regularity every four months. He had received great benefit from medicinal treatment, and it was only recently that the failure of a prescription which he had received in Berlin led him to seek surgical relief. The pain was paroxysmal in character, began inside the left ear, and he invariably pressed his finger into the auditory meatus in an attempt to demonstrate where the pain was. The pain did not affect the auricle, but radiated deep into the head and not into the throat; it spread a little in front of the ear, but never went forward into the lower jaw, cheek, gums, tongue, or temple. The spasms, so far as he was able to tell, were not excited by anything in particular; this was an unusual feature, for glosso-pharyngeal neuralgia is generally excited by swallowing. During the pains, which were of brief duration, he grimaced, turned his head to the left, and held his face in his hands.

In the belief that this was an example of trigeminal neuralgia of unusually limited extent, alcohol injections had already been tried, and he had six months' freedom from pain after one of these. In view of later developments this relief was probably a coincidence, but it was very misleading. The return of paroxysmal pain made it evident that something more drastic must be undertaken, and in the belief that we were dealing with an unusual trigeminal neuralgia a fractional division of the sensory root was performed under local anæsthesia, helped out by a little ether whilst the actual root was being uncovered and cut. The patient made an uninterrupted recovery, but before his discharge at the end of fourteen days there were already suspicious discomforts in the ear, of the old kind, and he seemed apprehensive. His fears were well-grounded, and three months later he was admitted with pains rather worse than before. Not having quite such firm faith then, as I have now, in the permanence of relief after fractional root section, it seemed possible that the pain might have been due to some fibres destined for the auditory meatus having escaped division, presumably owing to an anomalous grouping in the root. Accordingly, again under local anæsthesia, the wound was reopened, the root rapidly exposed, and the remaining fibres cut, and, in addition, the third division was sectioned at the foramen ovale intracranially, to allow of no possible misinterpretation of the result. This operation solved the problem, for not only did the pain in the ear return in three days, but it now appeared for the first time in the left fauces. Further, the attacks were constantly precipitated by swallowing, so that he was almost unable to drink. It was now clear that we had been deceived as to the true origin of the pain, as so many clinicians have been before us, and that the glosso-pharyngeal nerve would have to be resected if we were to cure him.

We had a choice of the posterior fossa route advised by Adson and Dandy, or a high extracranial division. In view of his age, the latter seemed to be the wiser course, though there was some risk of failure, for unless the nerve was pulled out of the jugular foramen after dissection close to the base of the skull the tympanic branch, which had caused so much trouble, would escape. Through a long incision at the anterior border of the sterno-mastoid muscle on to the mastoid process the glosso-pharyngeal nerve was sought. A free section of the fibres of the sterno-mastoid was necessary, as the man had a short, obese neck. After a very difficult dissection the glosso-pharyngeal nerve was identified high up, separated of its extracranial vagal connexions, and avulsed at the jugular foramen by strong, steady traction.

From the time of his recovery from the anæsthetic to the present day the patient has been entirely free from pain. Examined in June, 1931, fifteen months after the last operation, he declares himself to be extremely well, pain free for the first long time in 38 years, and is very active for his 71 years.

The accurate testing of sensation in the throat is extremely difficult, but the patient is quite aware of a difference between the two sides. The vagus was slightly contused during the avulsion, for he had a left side paralysis of the vocal cord and some difficulty in swallowing. This recovered slowly, but it was five months before all these additional troubles had subsided. Fortunately, this handicap impeded his recovery very little indeed. There is profound anæsthesia of the cheek and palate, and although he can recognise touch over the left fauces and tonsil he states that it is much more numb than the right side. Palatal movements are perfect.

Comment.

The glosso-pharyngeal nerve supplies the middle ear, mastoid air-cells, and Eustachian tube by means of the tympanic nerve. This leaves the petrous ganglion actually inside the jugular foramen, and does not appear outside the skull. It follows that this branch is inaccessible, and pain arising in it can only be stopped by an avulsion at the base of the skull, which will probably tear the tympanic nerve as well; or by an intracranial section of the glosso-pharyngeal trunk before the branch has been given off. The pharyngeal supply of the nerve to the tonsil, posterior pillar of the fauces, and base of the tongue can be easily secured in the neck. Hence the cervical approach to, and extracranial division of, the nerve is more fitted for those cases in which faucial pain is dominant, but, even then, avulsion rather than clean section should always be performed.

My own case, on grounds of pure logic, was better fitted for the high (intracranial) section, but I judged his age to be against it, and fortunately the operation was entirely successful.

Purdon Martin's case showed the same limitation of pain to the tympanic branch in its initial stages, but for a shorter period, before extension to the throat; this was also the case in two of Doyle's patients. Martin compared this divisional electivity to that so common in trigeminal neuralgia, and my case enables me to confirm this view absolutely.

The innervation of the ear is complicated, and there might be doubt as to whether the glosso-pharyngeal through nervus tympanicus or vagus through ramus auricularis is the real cause. Sicard and Robineau expressed that doubt by the treatment they adopted for their cases (section of the glosso-pharyngeal, pharyngeal branches of the vagus, and excision of the superior sympathetic ganglion). But the syndrome of pain in the ear and in the throat can now clearly be regarded as glosso-pharyngeal, for clean intracranial division of the nerve has cured the pain absolutely. Crises of pure vagal disturbance have not been recognised save as a parasyphilitic phenomenon. The only disturbing feature about the crispness of the picture of aural and pharyngeal pain is Temple Fay's experiences with hopeless malignant disease of the pharynx, for in one of his cases pain in the throat was not relieved by a glosso-pharyngeal section, and in another was cured by cutting the vagus, the ninth nerve remaining intact. These were in examples of hopeless malignant disease, and run counter to the general mass of experience, such as it is. In my own view it seems to be certain that the vagus is chiefly motor to the pharynx and the glosso-pharyngeal chiefly sensory, no new idea but a reaffirmation of anatomical teaching borne out by clinical experience.

One other point is worthy of comment. It has been the custom amongst surgeons to explain the pain in the ear experienced by some sufferers from carcinoma of the tongue as referred along the lingual branch of trigeminus. But anterior lingual growths rarely produce it, and it is my impression that pain deep in the ear is only felt when the growth is far back and invades the fauces. It is therefore more likely to be glosso-pharyngeal than trigeminal. Pain referred to the tragus might be trigeminal, but not pain deep in the ear. After trigeminal sections there is surprisingly little anæsthesia in the auricle, and after glosso-pharyngeal section none at all, for it supplies the deep structures only. None the less, two or three cases of glosso-pharyngeal neuralgia in the literature have had painful ears, notably one case of Harris's. Nor is there any palsy of the soft palate or pharyngeal constructors unless the vagus has been coincidentally damaged.

Treatment.

As Harris has observed, and Martin supported the view, medicinal treatment may be successful for a long time. My patient obtained relief for years by drugs. No doubt these patients may have received drug treatment longer than trigeminal neuralgics, since the individuality of the affection has only recently crystallised out. But now that its identity is established recourse will be likely to be made to surgery rather earlier. As to the choice of route, there can be no doubt that the intracranial operation is the easier, and is therefore preferable. Even in the hands of those skilled in operations on the neck, the isolation and avulsion of the glossopharyngeal is a difficult undertaking and calls for gentleness and skill. In a thick-necked patient the nerve is very high and pharyngeal branches of the vagus may be mistaken for the nerve sought (vide Adson, case 2). Further the difficulty of ensuring section of the tympanic nerve is a disadvantage. It has succeeded, none the less, in Adson's hands and in my own. Temporary impairment of vagal functions may occur whichever route is employed, but fortunately does not seem to invalidate the result. Branches pass between the ninth and tenth nerves in the jugular foramen and avulsion of the former may cause slight damage to the vagus. The intracranial operation is essentially one for the surgeon familiar with the anatomy and methods of access to the lateral recess.

BLOOD TRANSFUSION IN TWO CASES OF AUTO-AGGLUTINATION.

By W. Stewart, M.D. Glasg.,
ASSISTANT PATHOLOGIST TO THE ROYAL HOSPITAL, WOLVERHAMPTON;

AND

E. E. Harvey, M.R.C.S. Eng.,
HOUSE PHYSICIAN TO THE HOSPITAL.

The phenomenon of auto-agglutination is not common, and transfusion in such cases is still more rare. We have not been able to trace, in the literature at our disposal, one case in which a transfusion was performed. In view of this it was thought advisable to place on record two cases which have recently come under our investigation.

In this department, although a grouped voluntary transfusion list is maintained, blood-matching is performed in every case before a transfusion is given. The serum of the recipient is matched against a red-cell saline emulsion of the proposed donor.¹ In both the following cases we found that the serum of the patient agglutinated the red cells of the donors. Some of the latter belonged to Group O (IV. Moss); there was therefore something more than the usual iso-agglutination in these cases. The blood-matchings were performed at laboratory temperature. At the suggestion of Dr. Dyke, the slides on which the matchings had been done were transferred to the incubator (temperature 37° C.), and it was found that the agglutination disappeared.

THE TWO CASES.

Case 1, a married woman, aged 32, and seven months pregnant, had not been feeling well since the beginning of pregnancy. She complained of lassitude, headache, and noises in the head. Her appetite was poor, and there had been some recent swelling of the feet. There had also been some fairly severe hæmorrhage from piles. She was extremely pale and thin. The conjunctivæ were yellowish, and there was some slight œdema of the lower limbs. The heart was not enlarged but there was a soft apical bruit. The reflexes were somewhat diminished, but the plantar responses were both flexor. The interest centred around her blood condition. On admission on Jan. 24th, 1931, her blood count was:—

Red cells..	.. 1,040,000	Polymorphs	..86 per cent.
White cells	.. 8,000	Lymphocytes..	13 ,,
Hæmoglobin	.. 18 per cent.	Monocytes	.. 1 ,,

Mean diameter of red cells approx. 8 μ. Six nucleated red cells in counting 100 white cells. Slight inequality in size of red cells.

With such a blood picture a transfusion was suggested, but it was found that the serum of the patient produced universal agglutination. The patient was herself Group B (III. Moss), and she had been tested against three donors of Group O (IV. Moss). When the slides were transferred to the incubator the clumping in all cases disappeared.

On testing the red cells of the patient against her own serum there was slight, but distinct agglutination at laboratory temperature, and intense agglutination at ice-chest temperature (4° C.). Agglutination also occurred between the patient's serum and the red cells of all other Group O (IV. Moss) individuals at 4° C., although this was slow in developing, but there was no agglutination when the matching was performed at incubator temperature. In view of the fact that the patient could not possibly agglutinate her own red cells at body temperature, a transfusion was agreed upon, her husband, Group O (IV. Moss), being used as the donor. Sixteen ounces of blood were given by the sodium citrate method, extra precautions being taken to maintain the blood at body temperature during the procedure.

The patient took the transfusion exceedingly well; there was no distress, and there was no appreciable increase in the pulse-rate. About twenty minutes later there was a sudden collapse, and the temperature rose to 104° F. She was extremely dyspnœic, but was able to tell us that she was suffering from pain and distress across her chest. Her condition gave rise to much anxiety. Tepid sponging was ordered, and morphia and adrenalin were given subcutaneously. These were followed almost immediately by cessation of all the symptoms, and there was no further period of anxiety. On the days following the transfusion there was no evidence of intravascular hæmolysis or clumping of the red cells, and no hæmoglobinuria or jaundice. The patient made a good recovery on preparations of iron. The following blood counts show the course of the convalescence:—

Jan. 27th: Red cells, 1,280,000 per c.mm.; reticulocytes, 10,800 per c.mm.
Jan. 31st: Hæmoglobin, 22 per cent.; red cells, 1,610,000; reticulocytes, 151,000.
Feb. 7th: Hb, 37 per cent.; red cells, 1,890,000; reticulocytes, 71,820.
Feb. 12th: Hb, 51 per cent.; red cells, 2,420,000; white cells, 9200; reticulocytes, 16,900.
Feb. 20th: Hb, 61 per cent.; red cells, 3,120,000; white cells, 10,300; reticulocytes, 15,600.

She was delivered of a full-time living child on

March 21st. A few days after her confinement she still showed the cold auto-agglutination of her own red cells, and also the red cells of Group O (IV. Moss) individuals.

Case 2, a girl aged 5½, was one of thrombocytopenic purpura. A petechial hæmorrhagic rash was noticed five days before admission. It had started on the face and spread downwards. Two days before admission bleeding commenced from the gums and nose, and there was also some melæna and slight hæmatemesis.

On admission the child was very anæmic, blood was oozing from the gums and nose, and there was a generalised hæmorrhagic rash. The breath smelt of acetone. In order to arrest the hæmorrhage a transfusion was suggested. On doing the routine blood-matching we found that the serum from this patient agglutinated the red cells of each donor tested. The patient herself was Group A (II. Moss). Her serum had been put up against the red cells of her father, Group A (II. Moss), her mother, Group A (II. Moss), and those of another, Group O (IV. Moss). Agglutination occurred in all cases at laboratory temperature. The matching was repeated at incubator temperature, and the clumping disappeared.

The condition of the patient was desperate, and it appeared very doubtful whether she could stand a reaction such as was experienced by the patient in Case 1. In view, however, of the fact that unless the hæmorrhage were stopped death appeared inevitable in any case, a transfusion of 8 oz. of blood was given. The donor was the Group O (IV. Moss). The transfusion was taken well. About 45 minutes afterwards the patient collapsed. The temperature rose to 105° F., there was marked dyspnœa, and the child appeared to be suffering from severe shock. After our experience with the previous case adrenalin and morphia were given immediately, and tepid sponging was done. These were followed within a short time by complete recovery and cessation of the hæmorrhage.

On the following day the child developed a bronchopneumonia, probably aspiration in type. This ran a severe course, but the chest cleared completely in 12 days, and the child was discharged fit and well some ten days afterwards.

On admission the blood picture was as follows:—

Hæmoglobin	.. 32 per cent.	Polymorphs.	..71 per cent.
Red cells	..1,520,000 per c.mm.	Lymphocytes	..22 ,,
White cells	.. 6,700 ,,	Monocytes	.. 7 ,,

No morphological abnormalities of red or white cells; platelets, 1 per 1000 red cells; total, 1520 per c.mm. A few giant platelets noticed.

The prick which had been made in the lobe of the ear for this blood count was still oozing some three hours afterwards, but all bleeding ceased at the commencement of the rigor after transfusion. Subsequent blood counts were:—

May 14th (two days after the transfusion): Hb, 24 per cent.; red cells, 1,510,000; white cells, 13,200; platelets, 15 per 1000 red cells; total, 22,650 per c.mm.

May 26th (during the pneumonia): Hb, 29 per cent.; red cells, 2,010,000; white cells, 16,200; platelets, 146 per 1000 red cells; total, 293,460 per c.mm.

June 12th (two days before discharge from hospital): Hb, 54 per cent.; red cells, 3,730,000; white cells, 10,400; mean diameter of red cells, 7 μ; platelets, 88 per 1000 red cells; total, 328,240 per c.mm.

The patient was discharged in a perfectly healthy condition. The course of the convalescence was so satisfactory that there was no necessity to consider splenectomy, which Piney calls "the one almost certain method of inducing the onset of a thrombocyte crisis."[2] The giant platelets were noticed at the first blood examination only.

In this case some relatives of the child were also tested for auto-agglutination. The father and another daughter, both of whom were Group A (II. Moss), showed no auto-agglutination in the cold, but the mother, Group A (II. Moss), showed marked auto-agglutination at ice-chest temperature; this required fully two hours to develop. When the serum of the mother was put up against the red cells of Group O (IV. Moss) agglutination occurred rapidly at laboratory and ice-chest temperatures.

COMMENT.

The object of this paper is to show that cases which manifest auto-agglutination can be transfused. The recognition of these cases is rare; possibly they are much more common than is generally believed.

At a meeting of the Pathological Section of the Royal Academy of Medicine in Ireland,[3] W. Boxwell reported a case, and J. W. Bigger reported that he had been able to trace 22 cases of true auto-agglutination. Li Chen-Pien,[4] in an excellent article, describes his observations in such a case, and also gives a review of the literature.

The agglutination is not the usual iso-agglutination, but is apparently a temperature phenomenon and does not occur at body temperature. As a rule, the lower the temperature the more intense is the clumping of red cells. In view of this fact it is essential that the blood of the donor be not allowed to cool during the transfusion. In such cases the transfusion is apparently followed, after a short interval, by a severe reaction, but the symptoms can be relieved by morphia and adrenalin.

The experimental side of these cases has not been considered, as, at the present, this part of the work is incomplete.

SUMMARY.

1. Two cases of cold auto-agglutination are here described, one of anæmia complicating pregnancy and the other a case of thrombocytopænic purpura (Werlhof's disease). 2. In both cases transfusion was essential and was performed. 3. The transfusion in each case was followed by a period of extreme distress for the patient. 4. The symptoms of this distress were relieved by morphia and adrenalin. 5. In neither case was there any evidence of intravascular lysis of the red cells. 6. A thrombocyte crisis can be induced in cases of thrombocytopænic purpura by blood transfusion. 7. Auto-agglutination may be hereditary, as it was also present in both mother and daughter, Case 2, but it is impossible to formulate general rules on one case alone. 8. This phenomenon is not a manifestation incident to anæmia, as it was present after the anæmia had disappeared. 9. Group O (IV. Moss) still remains a universal donor. 10. Blood-matchings and blood-groupings should be done at body temperature and not at laboratory temperature as hitherto.

The blood-groups are given in terms of the international classification, those of Moss in parenthesis.

We are much indebted to Dr. S. C. Dyke, director of the pathological department of the Royal Hospital, Wolverhampton, who recognised the condition in Case 1, and to Dr. J. H. Sheldon and Dr. J. N. McTurk, visiting physicians, the Royal Hospital, Wolverhampton, for permission to use the clinical notes of these cases.

OBSERVATIONS ON A SPHERULE RECENTLY DESCRIBED IN DISSEMINATED SCLEROSIS.*

BY J. A. BRAXTON HICKS, M.D., M.R.C.P. LOND., D.P.H.,
DIRECTOR OF PATHOLOGICAL LABORATORIES, WESTMINSTER HOSPITAL;

AND

F. D. M. HOCKING, M.B., M.SC. LOND., F.I.C.,
ASSISTANT PATHOLOGIST AND BIOCHEMIST TO THE HOSPITAL.

(From the John Burford Carlill and Neurological Research Laboratories, Westminster Hospital.)

THE spherule described by Miss K. Chevassut[1] as the specific virus in disseminated sclerosis, and its employment as the basis of a vaccine in the treatment of this disease by Purves-Stewart,[2] has given rise to considerable discussion during the past two years.

Smith and Ransome[3] also observed this spherule in cases of disseminated sclerosis, but did not have the opportunity of investigating other types of disease. Carmichael[4] was unable to confirm Chevassut's findings, and a series of cerebro-spinal fluids submitted to her by him under test conditions were reported on in such a way as to cause him misgivings as to the validity of her original observations. Lépine and Mollaret,[5] of Paris, have recently published observations which still further throw grave doubts as to the spherule described by Chevassut being specific for disseminated sclerosis, since they have observed them in many other conditions. More recently still Tronconi,[6] of Pavia, confirms the findings of Lépine and Mollaret, and in addition to observing these spherules in liquid preparations has succeeded in obtaining them on agar slip-cultures.

Shortly after the original article by Miss Chevassut appeared we published the results of experiments on the biochemical and pathological effects of cultures of this spherule which were supplied to us by her.[7] In view of the experiments now to be described many of these deductions must be regarded as of little value.

As the result of a series of experiments in the nature of a repetition of the work of Chevassut, and before the publication of the work of Carmichael and Lépine, we began to have serious doubt about the specific nature of this spherule in disseminated sclerosis. This fact was made public with a promise of a fuller communication as soon as possible.[8] The present paper seeks to fulfil the promise. The preliminary experiments followed the lines laid down by Chevassut in her original paper, but the subsequent experiments were altered in the manner shortly to be described.

EXPERIMENTS.

Miss Chevassut in her first paper, and in subsequent communications, has stressed the fact that it is essential that the spinal fluid be received *direct* into the culture medium, or at the latest a very short time after. She claims that the discrepancy between her results and the diagnosis in the test series sent to her by Carmichael was due to delay in transmission of these fluids. Fluids from disseminated sclerosis were therefore investigated as follows.

One portion of each fluid was treated exactly as in the original technique, another was allowed to stand on the laboratory bench in the light for 48 hours, while a further portion was placed in the ice-box for a similar period, before being finally added to the broth and serum. It was found that whether the fluid was added direct to broth and serum, or whether allowed to stand on the bench or in the ice-box before being added to broth and serum, that on incubation these spherules appeared, the appearances being identical as regards morphology and number. It therefore does not appear that this objection of Miss Chevassut's is a valid one in the experiments carried out by Carmichael.

Stress has been laid on the necessity of using human serum, but rabbit's serum has been found to give quite as good results. Horse serum is not quite as efficient. The reaction of the broth has been stated to be of the greatest importance, and broth prepared by Hartley's formula was used in the original experiments. Ordinary tryptic broth, and even Lemco broth, gave almost equally good results, and one batch of quite roughly standardised Lemco broth seemed equally efficacious. Thus from these experiments many of the essentials laid down in the original paper seemed open to doubt. All attempts to obtain colonies on agar slip-cultures, after the technique of Welch[9] were unsuccessful both in cases of disseminated sclerosis and in all other fluids investigated, but Tronconi has succeeded in obtaining these in disseminated sclerosis and in other lesions of the nervous system.[6]

In the course of the preliminary investigations a considerable number of spinal fluids from lesions other than disseminated sclerosis were investigated, and spherules indistinguishable from those seen in disseminated sclerosis were observed.

The question of serum contaminants was not neglected, and it is admitted that these may present some difficulty; after a certain amount of experience these bodies can be differentiated from the spherules which form the subject of this paper. As a further safeguard (in the series of fluids to be subsequently described), a control tube of the same batch of serum and broth was incubated along with the serum-broth plus spinal fluid. In this way by examining drops taken from the control tube and the test mixture any appearances due to the spherule are readily appreciated. Further, it became a matter of constant observation that the controls remained quite clear to the naked eye while the positive tubes (after incubation for 24 hours to five days) presented a definitely turbid appearance. This turbidity, and therefore the appearance of the spherule, is caused, in our opinion, by the interaction of substances in the cerebro-spinal fluid and the blood-serum. Serum and broth alone do not produce this turbidity. Nor does it appear to be obtained from such cases of normal or hysterical patients that we have had the opportunity of examining. As it has not been possible to obtain a reasonable number of strictly normal fluids on which to make investigations, it would be wrong to express any definite opinion as to their constant appearance or absence in normal conditions.

It can be asserted that spherules, having apparently all the characteristics of the spherule described by Chevassut, can be observed in a large number of other abnormal conditions of the spinal fluid; and it is not possible to confirm her statement that they are specific to disseminated sclerosis. An examination of the Table shows that a positive culture can be obtained in all cases of organic nervous disease, when there is active breaking down of nervous tissue. This suggested that the spherules, granules, &c.,

---

* The major portion of this paper was communicated to the Pathological Society of Great Britain and Ireland on July 3rd.

are formed as the result of breaking down of blood protein by products of cellular disintegration—i.e., enzymes.

To test this possibility, a normal, fresh brain was stripped of its meninges, the grey and white matter separated as far as possible from blood-vessels, &c., and ground up with sharp sand. The resultant mixture was filtered through fine Berkefeld filters until it was optically clear. This extract was then used in a broth and serum mixture in the place of the cerebro-spinal fluid. In 24 to 48 hours an optical appearance consisting of spherules, granules, and filaments indistinguishable from that obtained in disseminated sclerosis was seen.

TABLE OF RESULTS.

	Cases.	
Cerebral thrombosis	1	Spherules present.
„ tumour	3	Spherules present in all.
„ abscess	1	Spherules present.
Spinal curvature	1	No spherules observed after 5 days.
Disseminated sclerosis	5	Spherules present in all.
G.P.I.	4	
Tabes	1	Spherules present.
Spastic paraplegia	1	
Parkinson's Disease	1	
Subacute combined degeneration of cord	1	
Amyotrophic lateral sclerosis	1	
Paralysis agitans	1	
Epilepsy	1	
Amentia	1	
Sciatica	1	
Uræmic fits	1	
Tuberculous meningitis	2	Spherules present in one case and absent in the other.

The Table is a list of 27 cerebro-spinal fluids treated under the same conditions. The conditions were that each fluid was exposed on the bench for 48 hours before being transferred to the serum-broth mixture (Hartley's broth, pH 7·6). This mixture was then passed through a small Berkefeld filter and incubated. A control broth-serum tube was similarly passed through a filter and incubated. Examinations of control and test cultures were made at intervals of 24 hours up to five days.

Thus, out of 27 cases, in which disseminated sclerosis only accounted for five of the series, 20 conditions other than disseminated were positive for the spherule and two negative.

CONCLUSIONS.

(1) The spherule described by Chevassut is not specific to spinal fluids of disseminated sclerosis, but can be found in the fluids from many other conditions. This agrees with the published findings of Lépine, Mollaret, and Tronconi. (2) Many of the essential conditions, especially that of the need for immediate transference of the spinal fluid to the broth-serum mixture, laid down in the original paper appear to be open to considerable elasticity on further investigation. (3) We have not been able to obtain agar slip-cultures, but this has been accomplished by Tronconi in disseminated sclerosis and in other lesions of the nervous system. (4) We do not consider the spherule to be a virus, but a flocculation or precipitation phenomenon produced by the interaction of the spinal fluid and blood-serum. (5) It has not been possible to study a sufficient number of normal fluids in order to state whether this phenomenon indicates an abnormal fluid or whether it occurs with any fluid.

In conclusion, it is desired to thank the physicians of the Westminster Hospital and of the Springfield Mental Hospital, Tooting, for their assistance in supplying fluids for these investigations.

CLINICAL AND LABORATORY NOTES

DIPHTHERIA TOXIN OF HIGH VALUE.

BY C. G. POPE, B.SC. BRISTOL,
BIOCHEMIST, WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES.

FOR a number of years we have steadily increased the strength of the diphtheria toxin produced at the Wellcome Physiological Research Laboratories, and I feel it would be of interest to place on record the details of one batch of toxin of unusually high value. Working with tryptic digest medium, we have frequently obtained toxins with an Lf. value of 40 units per c.cm.* Recently a medium prepared from horse-muscle infusion and proteose peptone, containing sodium acetate, and sterilised by filtration through a Berkefeld candle—both important points—gave toxin with an Lf. value of 50 units per c.cm. This toxin was examined at the National Institute for Medical Research by Mr. Percival Hartley, D.Sc., who obtained the following results: M.L.D., 0·00038 c.cm.; Lo., 0·022 c.cm.; L+, 0·026 c.cm. I hope shortly to publish full details of the method of preparation of this medium and of others which have been found to give high-value toxins.

I wish to express thanks to Dr. Hartley for the tests which he carried out on this toxin, and to Dr. R. G. White for information regarding the methods used for preparing diphtheria toxin at the Belmont Laboratories.

ANTITOXIN OF EXCEPTIONAL POTENCY.

BY A. T. GLENNY, B.SC. LOND.,
SEROLOGIST, WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES.

IT is of interest to other workers to place on record instances of antitoxin of exceptional potency. Among a group of 52 horses recently immunised with diphtheria toxin containing an average of 25 Lf. units per c.cm., prepared by Mr. C. G. Pope, seven produced serum containing from 2000 to 2500 units of antitoxin per c.cm., three between 2500 and 3000, and one contained 3000 units per c.cm. As this is the strongest unconcentrated antitoxin yet produced at the

---

* The abbreviation Lf. is a descendant of Ehrlich's Lo = Limes null—i.e., the dose of diphtheria antitoxin which, when mixed with one test dose of toxin, and injected into a guinea-pig, will prevent the appearance of any local œdema; similarly L+ is the amount of antitoxin which just fails to prevent the death of an animal. Lf. is the amount of toxin which (f) flocculates with one unit of antitoxin when mixed in the Ramon method. —ED. L.

Wellcome Physiological Research Laboratories, we sought an independent confirmation of our test; Mr. Percival Hartley, D.Sc., kindly offered to test this serum in the Department of Biological Standards, National Institute for Medical Research, and confirmed our findings. We have also to acknowledge the kindness of Mr. P. Bruce White, of the same department, in comparing the value of two samples of *Bacillus welchii* antitoxin, one an unconcentrated serum containing 800 to 900 units per c.cm. and a concentrated sample (produced from lower value sera) with 1300 units per c.cm.

The advantage of strong toxin cannot be too greatly emphasised, not only for the production of high-value antitoxin, but also for use as test toxin. The accuracy of any test can almost invariably be increased by the use of larger test doses of toxin. The use of a test dose of diphtheria toxin equivalent to 10 or 50 units of antitoxin increases the accuracy of titration, and tetanus antitoxin can be tested with advantage at the 2 rather than at the 0·2 international unit level.

INTRAMUSCULAR INJECTIONS OF CALCIUM.

By T. Izod Bennett, F.R.C.P. Lond.,

PHYSICIAN TO OUT-PATIENTS, MIDDLESEX HOSPITAL.

The administration of calcium for the treatment of tetany has always been complicated by the tendency of calcium salts to produce necrosis on injection. This can be overcome when the intravenous route is employed, but makes the use of intramuscular injections for this purpose very difficult, if not impossible. Although in cases of acute tetany the intravenous method is the one of choice, it is not readily applicable in chronic cases.

I have recently been confronted with a severe case of chronic tetany, due to persistent steatorrhœa, which could not be controlled by the oral administration of calcium owing to defective alimentary absorption. It was, however, successfully controlled by the intramuscular injection of tetanol, a solution of calcium gluconate and lævulinate prepared by the Crookes Laboratories.

For the special purpose of this particular case, Messrs. Crookes prepared ampoules containing 5 c.cm. of a 3 per cent. solution of this substance, and these were given daily into the buttocks for a period of three weeks. These 21 injections were not attended by pain, and upon only one occasion was any local inflammatory reaction noted; the substance was rapidly absorbed, and arrest of the tetany successfully secured.

Enlargement of Isle of Wight Hospital.—Princess Beatrice recently opened extensions of this hospital at Ryde which have cost £16,000. They include a new women's surgical ward of 12 beds, an enlargement of the X ray department, and improved accommodation for nurses and the domestic staff.

Preston Infirmary.—Last year the in-patients at this institution treated to a conclusion numbered 6397, an increase of 617; there were 23,507 new out-patients, an increase of 2120. Casualties numbered 8578, and in the four theatres 6388 operations were performed. Owing to the industrial depression the Workpeople's Infirmary Fund produced nearly £3000 less, and 1930 closed with a deficit on the year of £5170. The average annual cost of a patient was £109 10*s.*, the weekly cost £2 1*s.* 8½*d.*, and the cost per patient £5 4*s.* 7½*d.*

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

SECTION OF PATHOLOGY.

At the third session of this section on July 24th the chair was taken by Dr. R. G. Canti.

Epidemics.

Prof. **Major Greenwood** read a paper on the Factors Determining the Difference between an Epidemic of one Disease and that of Another. He pointed out that almost every word in his title alone required definition: what was a disease; what was an epidemic? Nevertheless, dialectical difficulties should not deter them from discussing a question which had interested the profession for thousands of years. According to Galen, there were three factors: the innate, temperamental and procatarctic, and the external atmospheric katastasis. In Galen's opinion it was rather the condition of those exposed to infection than the nature of the infection which determined the difference between epidemics. Sydenham, on the other hand, had enormously extended the sphere of the katastasis and popularised the doctrine of the epidemic constitution. In the year of grace 1931, epidemiologists were still wrangling about the problems of Galen and Sydenham. A via media must be chosen between the over-elaboration of the disciples of Sydenham and the over-simplification of academic bacteriologists. Experimental epidemiology was an attempt to simplify the study of general epidemiology by limiting the number of variable factors and by taking for study a herd of short-lived animals. These advantages were, of course, purchased at a heavy price, and the application of results to the human problems was analogical at two removes; there was a gap between the experimental mice and mice in general, and between mice and men. As a result it had been fairly well established that in herds of mice exposed to heavy risk of infection by *Pasteurella muriseptica* or *Bacterium aertrycke* the regular addition of healthy animals and careful exclusion of new infection would lead to the perpetuation of the disease through many generations. Though the infection might cease in small herds it would probably continue indefinitely in large herds. There was no conclusive evidence that environmental, non-specific factors modified the secular course of epidemicity in any significant way in these herds. Pre-immunisation greatly lowered mortality during the early herd life of the immunised animals, but ultimately the rates of mortality of pre-immunised and naturally immunised approximated to a level much above zero. Thus, it was unlikely that any artificially induced immunity would ever be more effective than that conferred in the ordinary course of herd life upon survivors of continuous infection. The very substantial advantage of pre-immunisation was that the survivors came into as good a position as the controls without having paid the price in high mortality, earlier on. No method so far tested would give a solid immunity—i.e., an approximation of the specific herd mortality to zero.

Prof. **W. W. C. Topley** agreed that the question set by the title could not be answered. The observation of "epidemic behaviour" over a large succession of waves might give a little information, but not much. It had been suggested—particularly by Boycott—that the study of mice in cages was not related to the facts of human disease; that mice did not bother to immunise themselves; that mankind depended much on immunisation, and that elephants would probably be found to depend on it still more. This was unfair to mice, which were amazingly good at immunisation, both against mouse typhoid and against ectromelia. There was no solid immunity to the latter disease. Prof. Greenwood had made immunisation appear of some value against virus diseases, but he and his colleagues had not achieved the protection they had expected to achieve against bacterial diseases. Herd vaccination had lengthened the expectation of life but had not conferred much protection. At a guess, the diseases which were mainly toxæmic fell very nearly into the virus group as regards immunological behaviour. Data on the frequency of second attacks of diphtheria, scarlet fever, measles, and typhoid were remarkably scanty. On the other hand, the answer to the question of whether antitoxic immunity, however-produced, was effective was probably in the affirmative. It seemed to be possible to secure good immunity against the streptococcus, but in scarlet fever the patients got tonsillitis; in puerperal fever it was possible to immunise against the toxin but not against the organism as such. The same was true of staphylococcal infections. Epidemiologists knew quite well the difference between diseases with different vectors, but it was nearly impossible to define the part played by each vector under clearly stated conditions. Prof. Topley confessed that he had absolutely no light on diet. A diet deficient in vitamins would doubtless increase the susceptibility, but the evidence was conflicting on whether a diet containing excess of vitamins would decrease it. Another unanswered question was whether this effect, if it occurred, was absolutely non-specific, or whether it favoured one sort of disease at the expense of another.

The variation in the virulence or epidemic potency of the parasite was probably a very important factor, but there was no valid evidence that it existed. Fluctuations according to virulence had been shown in the laboratory, but not under natural conditions. The existence of seasonal fluctuations was similarly doubtful. There was need of some means of measuring the relative importance of these different factors. Laboratory tests of immunity were very bad indeed, and far too much reliance was placed upon them.

Lieut.-Colonel C. A. GILL reminded the section that before 1919, when Prof. Topley had commenced his studies on mice, no progress had been made in epidemiology for 2500 years. Knowledge of the subject was at its very beginning. Moreover, epidemicity involved endemicity and ultimately the whole nature of disease. In his experience of malaria, plague, relapsing fever, and influenza, one of the most astonishing things was that, whether the disease was due to a bacterium and conveyed by an insect or whether it was conveyed by contamination in a laboratory, the epidemicity seemed to be entirely the same. Secondly, the old idea that an epidemic was due merely to some change in the specific parasite did not seem to hold water.

Dr. J. D. ROLLESTON stated that in his experience the proportion of recurrences of diphtheria under treatment remained constant at 1 per cent. He had seen only one second attack of small-pox, and second attacks were very rare in chicken-pox and typhus.

Dr. W. H. BRADLEY said that he had watched the throat flora in two waves of streptococcal tonsillitis in a school. Each wave had shown a uniform type, but the two types had differed, suggesting two definite waves produced by different serological strains. He exhibited graphs showing the tendency of a wave to stabilise itself after a while. Communities were, he suggested, saved from extermination in one epidemic by the onset of another, or, in nasopharyngeal disease, by the overgrowth of one strain by another.

The CHAIRMAN deplored the neglect of epidemiology, especially by the general practitioner. He asked what precautions should be taken on an outbreak of a disease with a high carrier and a low morbidity-rate, like meningococcal meningitis. It was impracticable to isolate all possible contacts.

Dr. W. G. BARNARD read a paper on

Infarction of the Myocardium.

This condition was, he pointed out, of general interest as the commonest cause of death in elderly persons. Knowledge of its morbid anatomy was necessary, because it might leave no visible signs in the heart and was frequently missed at autopsy. It could, however, be suspected partly from the history, and far more from the condition of the coronary arteries which were blocked. Death was not a direct result of the block. By experiment on dogs it had been found that ligature of the coronary arteries caused fibrillation of the muscle, due to interference with the neuromuscular control through the cutting-off of the blood-supply. Necrosis and a degeneration of the myocardium could only be seen if the patient survived for a considerable time. If scissors or probe were pushed down a coronary artery, it might easily be opened and a piece of atheromatous debris be removed without the operator finding the block, but if he made transverse sections he only required to know where the coronary arteries were. If the patient survived, the site of the lesion was marked by fibrous tissue, which might form a band or a series of lines and streaks which nearly always bore a deposition of clot. A certain amount of pericarditis was often found over the affected myocardium, which was nearly always in the left ventricle, where also aneurysms occasionally ruptured and caused hæmopericardium. The commonest cause of infarct in this region was atheroma of the coronary artery, with or without thrombosis. Emboli hardly ever occurred. In the rare younger cases an exactly similar condition might be due to aortitis. The orifices must always be examined carefully. Dr. Barnard showed a series of slides illustrating the post-mortem findings.

Dr. WILFRID MARSHALL read a paper on the

Spectra of Photo-electric Curves of Blood Pigments.

He said that the spectro-photometer gave accurate measurements of absorption in different parts of the spectrum and, if certain constants were maintained, would seem to be free from objections, although the curves did not represent the blood-spectrums seen by the eye. The instrument employed was a large-model constant-deviation wave-length spectrometer, with a polarisation photometer giving a triple field. Its average accuracy over the visible spectrum was about 1Å. A convenient solution of blood with well separated oxy-hæmoglobin bands showed a clear blue and, on diluting the solution, the α band was the last to go. The curve of the absorption coefficients showed the β band denser than the α; the limit of the β band towards the blue did not reach *O*, and was followed by increasing absorption as the violet was approached. This appearance was difficult to explain, but might be due to the residual yellow colour of blood solutions. Silver colloid solutions showed a similar tendency, and dilutions of electrargol were especially useful as a control. Dr. Marshall described experiments which seemed to show that a trace of methæmoglobin was normally present in the blood.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Breech Presentation.

THE section met under the presidency of Mr. **EARDLEY HOLLAND**, and the first session was devoted to a discussion on this subject.

ANTENATAL TREATMENT.

Miss **GERTRUDE DEARNLEY** emphasised the need for prophylactic external version on account of the higher fœtal mortality in breech deliveries and the disadvantages to the mother which included exhaustion after long labour and severe lacerations of the pelvic floor. In addition, there was the need for ascertaining the relative sizes of the head and pelvis which was, of course, impossible with a breech presentation. The time of election was the thirty-fifth week, but if an anæsthetic was necessary it was better to delay version till the thirty-seventh week, in case premature labour supervened. An anæsthetic was unnecessary unless the patient was nervous or the abdominal muscles very strong. If the presenting part was engaged it was helpful to raise the foot of the bed for a short time before starting, or it might be necessary to push the presenting part out of the pelvis per vaginam. Most failures to turn were due to the neglect of this precaution. The speaker had never seen any serious complications follow external version, though in one case slight ante-partum hæmorrhage occurred in a case of breech presentation with extended legs, where a good deal of force had to be used. The hæmorrhage soon cleared up and the patient went to term. It was best to turn the fœtus so as to maintain the attitude of flexion—namely, by pushing the head down towards the pelvis and away from the back—but, if this failed, movement in the other direction should be tried, and often succeeded. If the head did not sink into the pelvis, a binder should be applied. If version failed it was better to wait for a few days, and not infrequently spontaneous version took place in the interval. If the legs were extended, the important point was whether the feet were lying close to the head. If not, there was often quite good flexion of the body and version was usually possible under anæsthesia and without risk. If the legs were fully extended there was also extension of the child's body—points shown by X ray examination—and it was unwise to attempt version since damage might be done, and there was risk of bringing down a hand or arm by the side of the head.

FŒTAL MORTALITY AND INJURIES.

Mr. **G. F. GIBBERD** emphasised the high fœtal mortality in breech cases. In "uncomplicated" and "complicated" breech cases at a number of English hospitals whose last reports he had examined, the fœtal death-rates were 26 per cent. and 43 per cent., respectively. At Guy's Hospital the fœtal death-rate in primiparæ and multiparæ was 28 per cent. and 15 per cent., respectively, in uncomplicated breech deliveries. He did not classify first pregnancy or extension of the legs as complications. Amongst complicated breech cases, including in this class such conditions as prolapse of the cord and placenta prævia, the mortality was as high as 57 per cent. and 49 per cent., respectively. The most important cause of intranatal fœtal death was intracranial hæmorrhage, which accounted for 75 per cent. Next in importance was asphyxia, following cord compression after birth of the buttocks, and this accounted for almost all the remaining 25 per cent. He thought that the risk of drowning from premature respiration had been much overrated, and that a hot towel over the body during birth was useless. Injuries to the limbs were nearly always the result of bringing down extended arms which might cause either fracture of the humerus or an Erb's paralysis. The latter should be treated by putting the arm into the Israelite position, and allowing active movements daily when the splint was removed for bathing purposes. A fracture of the humerus was best treated by a straight Thomas's splint with elastic extension. Within a week or ten days firm union had taken place and the splint could be discarded.

MANAGEMENT OF BREECH LABOUR.

Mr. **ALECK BOURNE** said that at Queen Charlotte's Hospital the fœtal mortality in breech labour was 11 per cent. in primiparæ and 8 per cent. in multiparæ. One of the commonest causes of obstruction in breech cases was extension of the legs, and he believed that in every case in which this complication was present, if the child were of average or large size, one foot at least, and often two, depending on the size of the baby, should be brought down as a prophylactic measure as soon as the os was sufficiently dilated to admit a hand. Having brought down the legs, they should be folded as far as possible in the normal position by the buttocks, in order to get wider dilatation of the cervix. It was of great importance, however, to refrain from pulling at this stage. He thought that the most serious complication in breech cases was extension of the arms, because of the difficulty often experienced in flexing them and of the necessity for haste. Everything should be done to avoid extension of the arms, and the cases fell into two groups. In the first, the extension was "primary"—that is, the arms were extended when the legs were extended as a fœtal attitude before labour began. Over this group we had no control. "Secondary" extension was produced during labour entirely by pulling on the fœtus, and before the elbows could be reached and hooked out from the perineum. An incompletely dilated os predisposed to this, and it was for this reason that he advised folding the feet in the normal position by the buttocks. In that position they formed a larger mass than the breech alone, with both legs either extended or brought down, and, hence, caused better dilatation. In bringing down extended arms, he had found it useful to use a manœuvre of Potter's—viz., to press the lower angle of the scapula inwards. This brought the humerus downwards within reach of the fingers. In dealing with the aftercoming head the commonest mistake was to deliver it too quickly, especially if the head was not well flexed, the sudden moulding commonly leading to intracranial injury. The inspiratory movements of the fœtus at this stage were of little importance and were no indication for unduly hastening the birth of the head. The commonest cause of difficulty with the head was incomplete flexion, and this was especially liable to occur if the legs and arms had been extended, or if there were slight flattening of the pelvis. To obviate it, firm pressure should be made on the fundus during delivery of the body, combined with jaw traction with the index finger in the mouth, the body lying astride the forearm and the first and second fingers placed over the shoulders on either side of the neck. Before any traction was made on the shoulders the head should be flexed by gentle traction on the lower jaw and simultaneous firm pressure on the fundus. He had no experience of the use of forceps on the head.

Prof. **F. J. BROWNE** thought that version in breech cases was not always a safe operation for the fœtus, There was a risk, if much force were used, of premature separation of the placenta, or the cord might become entangled around the limbs, while alarming slowing of the fœtal heart after version, probably due to shock, was a well-known phenomenon. He had seen two cases of face presentation follow version, and he thought this might easily be produced if the fœtus were turned so as to cause extension. He disagreed with Mr. Bourne as to the advisability of bringing down a foot as a prophylactic measure when the legs were extended, preferring to interfere only if and when need arose, because of the necessity for getting the fullest possible dilatation of the cervix and vagina in order to obviate, as far as possible, difficulty from extended arms or the after-coming head. In his opinion, these, and not extension of the legs, were by far the most serious difficulties in breech cases. He strongly advocated the application of forceps to the after-coming head if moderate jaw-and-shoulder traction failed to deliver.

Mr. **Donald Roy** said that in the absence of large size of the child, a small pelvis, or uterine inertia, extension of the legs was not a frequentcause of still-*birth; much more important was extension of the* arms and head. To bring down the legs was no remedy for this, and might, in fact, by allowing the breech to slip quickly out with soft parts unstretched, increase the difficulty. If external version failed when the arms and legs were extended, and if there was anything to suggest from the appearance or history that the child was large, induction slightly before term was advantageous. In any case, where the child was large, the pelvis small, or inertia present, and especially if the legs were extended, one leg should be brought down early in the second stage, and right down as an excitant of good pains. Extension of the arms should be anticipated in such cases, and the arms in all cases felt for after the umbilicus was born. If not flexed, they should be brought down without delay, after which delivery of the head might have to be hastened by careful jaw-and-shoulder traction, assisted by efficient suprapubic pressure. Respectable results in breech delivery could now be obtained by labour in such cases taking place where people experienced in breech delivery were always available. This was difficult outside institutions or maternity homes staffed by efficient midwives. Mr. Roy quoted figures relating to 107 cases treated at the General Lying-in Hospital, York-road. There were 46 primigravidæ and 61 multiparæ, and the stillbirth and neonatal death-rate was 6·5 per cent. in the former and 8·2 per cent. in the latter.

Dr. **Chalmers Fahmy** said that at Edinburgh Royal Maternity Hospital the fœtal mortality was 22 per cent. and 21 per cent. in primiparæ and multiparæ, respectively. This mortality was very high, but it must be remembered that the cases were mainly delivered by somewhat inexperienced house surgeons. It would be interesting to know the fœtal mortality in 1000 cases delivered by practitioners of several years' experience. Extension of the legs was not in itself a serious cause of fœtal death. Delay in the arms and the head was the main cause. He did not think it wise to pull down extended legs as advocated by Mr. Bourne, *believing it better to interfere only* when necessary. In bringing down extended arms it was most important to wait till the axilla was almost in view; to attempt to release the arms earlier caused difficulty and increased the risk to the child. Fundal pressure should always be gentle. It could never flex an extended head; this could only be done by the finger in the mouth. Strong fundal pressure might cause intracranial hæmorrhage, and only jammed the extended head, as a whole, into the brim.

Dr. **W. H. F. Oxley** quoted statistics to show that only about half of all breech presentations occurring in pregnancy were turned, and that attempts at version chiefly failed in the cases with extended legs. The difficult cases, therefore, still remained, and obstetricians were getting only half the experience in breech deliveries that they obtained before prophylactic version was introduced. He thought that better results, on the whole, would be obtained if we directed our attention to improving our skill in extraction, and left all cases unturned in order to provide more material for teaching and practice. He described in detail the method used in breech delivery at the East End Maternity Hospital. A team of three was necessary—midwife, obstetrician, and anæsthetist. When the os was fully dilated he ironed out the vagina and extracted the fœtus very much in the manner advocated by Potter.

Mr. **Eric Stacey** advocated the introduction of speculum to hold back the posterior vaginal wal The vagina was then swabbed out, and the fœtus thu allowed to breathe or even cry. One could then effec delivery at leisure. He thought Cæsarean sectic was justified in elderly primiparæ if the legs we extended.

Prof. **J. B. Dawson** emphasised the need f external cephalic version in multiparæ, even previous labour had been easy, on account of th tendency for the children's weight to increase i suceeding pregnancies.

Dr. **J. C. Moir** thought that anæsthetics for versic were dangerous, especially if too deep or given by a unskilled person, and that ether was more dangero than chloroform. He disagreed with Mr. Bourne to the reason why extended legs caused difficulty an delay in labour. It was not, as held by Mr. Bourn owing to the greater cross section of the fœtus whe the legs were extended, but because the lower limb formed rigid bars which could not bend laterally, an so get round the curve of the pelvic canal.

The **President** said that the acid test of a goo obstetrician was the way in which he conducted breech delivery. Every hospital should have a senio resident medical officer, who could look after th delivery of difficult cases at any hour. All case should be delivered on the back, and episiotom should always be done if any difficulty were expecte If this were done no breech case should be lost, fo it was the compression by the vulval ring that s frequently caused intracranial damage. He totall disagreed with Mr. Bourne on the question of bringin down a foot as a prophylactic measure. Bringin down an arm was a difficult procedure that involve six or seven different movements, in which a doctors should be thoroughly skilled. He believe that external version should be done in every cas in which it was possible.

Distress Warrant against a Hospital.—A Newcastle-on-Tyne Moot Hall police-court recently th Newburn rating authority applied for a distress warrar against the Newburn and District Cottage Hospital (14 bed for arrears of rates amounting to £31 3*s.* 4*d.* Mr. E Redhead, the secretary of the hospital, explained that whe the Newburn Steel Works closed down last year the hospita lost 1500 weekly subscriptions of 1½*d.* each from workmer and that the assessment had been increased from £8 10*s.* t £40. The house surgeon had been working for a long tim without pay, and the hospital had kept going only by th exercise of drastic economy. The bench issued the warrant which is, however, to be withheld, the hospital agreeing t pay £10 down and £2 per month.

REVIEWS AND NOTICES OF BOOKS

The Practical Treatment of Diabetes.

By T. IZOD BENNETT, M.D., F.R.C.P. Lond., Physician with charge of Out-patients, Middlesex Hospital, Physician to the Royal National Orthopædic Hospital, formerly Beit Memorial Research Fellow. London: Constable and Co., Ltd. 1931. Pp. 107. 6*s*.

Dr. Izod Bennett has written a small book which will be very useful both to the general practitioner, who is faced with the charge of a patient suffering from diabetes, and also to the patient. The doctor can use other and bigger books if he wants to, but the choice of a suitable book for the patient is a difficult one; the medical details necessary for the doctor are apt to frighten a patient.

The necessary information about the amount of sugar in the blood and urine is given in a simple manner, under the title of diagnosis; most of the rest of the book is devoted to the details of the treatment with and without insulin. Dr. Bennett thinks that the initial treatment should always be started with a fast day, and the diet rapidly increased up to the suitable amount. If the glycosuria persists, or the blood-sugar remains too high, insulin should be used. The rules for its administration are clearly set out, and the technique of the injection is faultless. The description of complications requiring operation, and of the effect of pregnancy, are very clear. The amount of food recommended for the average patient is 85 C., 110 P., and 110 F., and the question is discussed whether the diet should be changed to one containing 100 or more grammes of carbohydrate, with proportionate reduction in the amount of fat. Useful diet tables are given on the 5-gramme basis.

Recent Advances in the Study of the Psychoneuroses.

By MILLAIS CULPIN, M.D. Lond., F.R.C.S. Eng. Lecturer in Psychoneuroses at the London Hospital Medical College. London: J. and A. Churchill. 1931. Pp. 348. 12*s*. 6*d*.

THE "Recent Advances" series is well known and justifiably appreciated, but a volume on the psychoneuroses presents peculiar difficulties and cannot be brought completely into line. The author felt that the subject was so vague and beset with such prejudices that his book is more a review of the whole development of psychotherapy than a simple and straightforward account of recent contributions to an accepted department of medicine. He has, however, tackled his difficult task courageously, and with a considerable measure of success. After a brief historical outline, he discusses at some length the psychoneuroses of the war, from the experience of which his own interest in psychotherapy, like that of the great majority of workers in all countries, was derived. He then surveys the present position of psycho-analysis in a chapter which will be of interest to the novice, but which is not likely to satisfy the psycho-analyst, as it confines itself to elementary principles. Possibly the author regards the recent work of this school as too technical for the book as he planned it.

Succeeding chapters deal with various theories of memory, the conditioned reflex, and physical concomitants of emotion, and a good deal is said about asthma. The differential diagnosis of the anxiety, hysterical, and obsessional states is dealt with fully and clearly. Dr. Millais Culpin is exceptionally well at home in the chapters on occupational neuroses and the psychoneuroses of industry, and these two chapters constitute an excellent review of modern work in this important branch. But the chapter on the analytical psychology of Jung, written by Dr. James C. Young, seems out of place. It is an interesting expression of personal opinion, but it fails to set out the contribution which Jung makes to clinical psychotherapy and the important respects in which his technique and approach differ from those of the Freudian or Adlerian schools. It is in strong contrast to the accompanying chapter on individual psychology by Dr. A. R. Redfern, which sets forth very distinctly the point of view and method of Adler. The two remaining chapters are also by independent authors: Dr. Emanuel Miller discusses the psychopathology of childhood in a interesting and well-informed essay, with a valuable bibliography, and Dr. J. R. Rees gives a very useful guide to the establishment and maintenance of the psychotherapeutic clinic.

This volume, if it does not give a complete account of the recent progress of psychotherapy, at least records many important advances, and presents the general practitioner—for whom the series is especially designed—with a good introduction to this most troublesome subject.

Pratique médico-chirurgicale.

Third edition. Published under the direction of A. COUVELAIRE, A. LEMIERRE, and CH. LENORMANT. Paris: Masson et Cie. Tomes i. to iv. 2 vols., Fr.300; complete work, 8 vols., Fr.1200. Pp. 8500 approx.

WE have now received the first four volumes of the third and much-altered edition of this French handbook of the Practice of Medicine and Surgery. The first two editions were published under different editors in 1907 and 1911, and the present work is almost entirely a new undertaking. When completed it will consist of eight large volumes in attractive binding, containing articles collected for the special purpose from some 200 collaborators. The object of the publication has been to provide a complete account of the practice of medicine and surgery in all their branches for the use of practitioners and students, with particular regard to clinical methods and treatment, and to enable the doctor rapidly to obtain practical information on diagnosis and treatment, with little attention to theoretical or hypothetical problems. For this purpose the subject matter is arranged alphabetically under the various headings of diseases, forms of treatment, drugs, and the like. The whole work has been written and printed in the course of a year, so that articles are strictly contemporary. Many well-known names figure among the list of collaborators, and the whole is in fact a remarkable exposition of the present-day practical French teaching.

The arrangement of subjects in alphabetical order carries certain disadvantages, and an encyclopædia of medicine is by no means the most suitable type of text-book for the student. On the other hand, if the titles are well chosen this arrangement enables the practitioner to find the information he requires quickly and easily. In these volumes the subjects have strange bedfellows. Successive articles in one group concern imbecility, immunity, impetigo, impotence, and in another anxiety, aortitis, aperitive, aphasia. Headings thus include diseases, symptoms, drugs, operative and other treatments, as well as more general matters such as auscultation, hygiene, epidemiology, and the like. Important subjects such as jaundice, diabetes, and arthritis are fully and clearly treated, and the notes under the names of drugs are excellent. Some of the numerous diagrams and pictures look rather old-fashioned. Some random attempts to test the completeness of the work failed to reveal any serious omissions. English readers will find much that is new to them in this work, which is a valuable book of reference to French medical practice.

Materia Medica.

Pharmacy, Pharmacology, and Therapeutics. Twentieth edition. By WILLIAM HALE-WHITE, K.B.E., M.D., LL.D., Consulting Physician to Guy's Hospital. Revised by A. H. DOUTHWAITE, M.D., F.R.C.P., Assistant Physician to Guy's Hospital. London: J. and A. Churchill. 1931. Pp. 712. 10*s.* 6*d.*

THERE must be few, if any, members of the medical profession in this country who have not heard of Hale-White's "Materia Medica." First published in 1892, it achieved a success so remarkable that from 1897 to 1905 a new edition was brought out each year. Since then fresh editions have appeared at frequent intervals, and the task of revision has now been handed over to Dr. Douthwaite. No alteration has been made in the characteristic features of the volume, which gives a full account of the preparations, action, and uses of all the official and many of the non-official drugs. It has been brought up to date by the introduction of drugs, such as ephedrine, avertin, and parathormone, which have come into favour during the last few years. A more detailed account of these might, with advantage, have been given, even if it entailed shortening the discussion of a number of others of less importance. There are a few curious errors in spelling—e.g., Novasurol is consistently spelled with two "r's," and Yohimbine with two "e's." We anticipate that the new edition will be as successful as those in the past.

International Clinics.

Volume IV. Fortieth Series. London: J. B. Lippincott Company. Pp. 309. 12*s.* 6*d.*

THE fourth volume of the Fortieth Series of International Clinics maintains a high level of interest. Three of the clinical papers come from France, one on the treatment of boils and carbuncles by injections of oxygen, another on the importance of the nervous system in the defence of the body against disease, and a third on rheumatism of dental origin. The staff of the pædiatric department of the Fifth Avenue Hospital of New York City present contributions on child health, on the treatment of weak feet in children, on procedures in the prevention and correction of oral deformities in children, and on a comparative study of posture in the first and second decade of life. The general staff of the same hospital have clinical contributions on the care of patients in the terminal stages of cancer, on toxin-antitoxin immunisation for diphtheria in adults, postpartum fever, and allergic purpura, while there are papers by other authors on hereditary epistaxis, on the differential diagnosis of peptic ulcer, and on subacute recurrent duodenitis. Among the most interesting features of this volume are reprints of some post-graduate lectures arranged by the Medical Society of New Jersey. Prof. J. E. Talley, of Philadelphia, deals with the treatment of cardiac diseases; Dr. T. Fitzhugh, Jr., of the same city, gives a review of modern advances in diseases of the blood; and Dr. Harry Gold, of Cornell, considers some of the larger problems of drug therapy. Dr. Gold points out that one of the stumbling blocks to the successful use of drugs is the question of dosage. The physician tends to think of the dosage of a drug in terms of weight or measure rather than in terms of activity or the effects it is likely to produce, with the result that often too small amounts are administered. As a general rule, in his view, no patient should be regarded as having been adequately treated with a drug unless the full therapeutic effects have been obtained, or minor toxic symptoms produced. There can be no question but that this is a sound general principle in therapeutics, though it requires some qualification, for there are many drugs which in toxic doses are definitely dangerous and, moreover, delayed effects may have to be reckoned with. At the same time the dangers can be reduced to a minimum if the physician has a working familiarity with the earliest signs and symptoms of toxic action and therapeutic effect. This is, in fact, though Dr. Gold does not state it explicitly, a strong argument for more attention being paid to the clinical aspect of pharmacology in the training of the student.

Wilhelm Conrad Röntgen

und die Geschichte der Röntgenstrahlen. By Dr. OTTO GLASSER, Cleveland Clinic Foundation. Berlin: Julius Springer. 1931. Pp. 337. R.M. 29.60.

Dr. Glasser has performed a task which is particularly opportune at this time, when we are removed from the glamour of the early days of radiology, and are yet, fortunately, still in touch with many who took part in, and can remember, its inauguration. The author has spared no pains in collecting information about the discoverer of X rays and his work, and he includes lighter touches in the form of contemporary cartoons and advertisements in the public press. It is a story full of romance. So many stopped on the threshold of discovery, notably Crookes, in 1879, and other workers who were using Crookes and Lenard tubes in the years immediately preceding 1895. All this is set out by Dr. Glasser fairly and fully.

It is remarkable to look back on this early history, and to see how large a part of the subject, as we know it, was covered within the first year of the discovery. There is, for instance, a reproduction in the book of cinematographic pictures of the frog's leg made by Dr. James MacIntyre, of Glasgow, and published in the *Archives of Skiagraphy* for 1897. Now almost forgotten is the metal X ray tube made in March, 1896, which lies in the collection of the British Institute of Radiology at the South Kensington Museum. In these days of elaborate apparatus, it is interesting to be reminded of such an advertisement as: "Set of superior X ray apparatus, as used at the Leeds General Infirmary, &c., complete sets, including 2½ inch coil, battery, and focus tubes, from £7 10*s.* 0*d.*"

The volume has interest for every worker, whether on the medical or the physical side of radiology. Although the author is resident in America, the book is written in German, and we hope that it will be made more accessible to English readers.

THE LANCET.

LONDON: SATURDAY, AUGUST 22, 1931.

THE NUTRITIONAL ANÆMIAS.

THE historian of internal medicine will probably consider that the most important advance of this decade was the clear recognition of the nutritional anæmias. Discoveries such as the isolation of insulin have led to the successful treatment of specific diseases, but the candle lit by G. R. MINOT and W. P. MURPHY's work on liver in pernicious anæmia has thrown light on many different forms of obscure ill-health which arise from nutritional causes and have anæmia as an outstanding feature. In a paper on Simple Achlorhydric Anæmia at the front of this issue, Dr. D. T. DAVIES calls attention to the group of cases described by KNUD FABER, in Denmark, by MILLS, WATKINS, and others in the United States, and particularly by L. J. WITTS,[1] in Great Britain. To WITTS's 50 cases Dr. DAVIES adds a similar group. The patient, usually a woman, suffers as a rule for years from indigestion and a progressive anæmia, characterised by marked reduction of hæmoglobin, but with little change in the red cell count. Achlorhydria is ordinarily present, but pepsin does not disappear from the gastric juice, and secretion of hydrochloric acid can often be demonstrated after injections of histamine. Treatment with large doses of the scale preparations of iron is usually very satisfactory.

The distinction between this type of anæmia and pernicious anæmia of the true Addisonian type is definite; the simple anæmia is almost confined to women, is insidious in its onset, taking many years to develop, is always marked by prolonged dyspepsia, is associated with a much reduced intake of food both as regards quantity and variety, produces a blood-picture essentially secondary in type, and responds quickly to administration of iron. Addisonian anæmia, on the other hand, is fairly rapid in its onset, affects both sexes, is often not associated with gastro-intestinal symptoms, is always accompanied by complete achylia gastrica, produces a blood-picture which is hæmolytic in type with macrocytes and marked reduction of the red cell count, and is not curable by the administration of iron. In spite of these contrasts there is, nevertheless, an aspect of close similarity between the two diseases in that both are associated with a reduction in gastric secretion and both may be considered as largely nutritional in origin. The work of W. B. CASTLE,[2] who showed that food subjected to the influence of normal gastric juice could produce striking amelioration in the symptoms of pernicious anæmia, has led to the introduction of extracts of gastric mucous membrane, whose beneficial effects have been almost as great as those of liver. It is believed that normal gastric juice can elaborate from protein of animal origin a substance which promotes normal blood regeneration; its exact composition is at present unknown, but it is neither hydrochloric acid, pepsin, nor any other recognised constituent of gastric juice. The school of thought which always laid stress on achlorhydria as the one constant finding in pernicious anæmia was formerly of opinion that the importance of the gastric change lay in the fact that it permitted bacteria to pass unchecked direct into the small intestine, but the more modern trend of reasoning is that achylia in pernicious anæmia connotes the absence of an essential but unknown chemical constituent of the gastric juice secretion. In simple achlorhydric anæmia, on the other hand, it is believed that prolonged dyspepsia with an ill-chosen diet, either as cause or effect, can, especially if hypochlorhydria be present, lead to such a defective assimilation of iron that the deficiency has direct and damaging results.

But the conception of nutritional anæmia extends far beyond these two diseases. The severe anæmia not infrequently seen after partial gastrectomy, or after the onset of chronic gastritis following gastro-enterostomy, has been described by G. GORDON-TAYLOR and others, and without providing a condemnation of gastric surgery, such observations serve as a warning against unnecessary reduction of gastric function. In this connexion it must not be forgotten that the pyloric mechanism is in itself a safeguard which tends to secure adequate nutrition. In all cases of achlorhydria without pyloric obstruction, the emptying time of the stomach is greatly accelerated, and the same effect tends to be produced when gastro-enterostomy or gastrectomy are performed; the result of this is not only that the food is under the influence of gastric juice for a much shorter time, but also that it reaches the small intestine too rapidly and in amounts too great for the digestive powers of that most important section of the alimentary canal. The effect is often apparent in the form of loss of fat in the fæces, and gas distention of the ileum and colon due to the hydrolysis of starch by microbic action instead of by the diastatic ferments of the succus entericus. Another form of nutritional anæmia is to be found in tropical sprue where, whatever the ultimate pathology may prove to be, the essential feature is failure of absorption by the alimentary canal. The result is that not only is fat prevented from reaching the blood stream in adequate quantities, but other essential substances, such as iron, calcium, and vitamins, are insufficiently absorbed, and a striking anæmia is one of the consequences. The Plummer-Vinson syndrome, in which dysphagia is added to the symptoms commonly seen in severe achlorhydric anæmia, is yet another instance of a disease in which malnutrition plays a major part, for it has been shown that even if the dysphagia is not the primary cause

ANNOTATIONS

DRUGS AND THE PRACTITIONER.

In a course of lectures delivered to graduate students in New Jersey (and reviewed on p. 408) Dr. Harry Gold shows how easy it is, in the evaluation of therapeutic agents, to be led into serious blunders by inadequate experiments, insufficient controls, or unsuspected sources of error. A common mistake is to focus attention too closely on a single effect produced by a drug, without realising the numerous combinations of action which might give rise to it. The guanidine derivative, synthalin, for example, reduces the blood-sugar after oral administration, and was therefore employed and recommended in the treatment of diabetes. But a clearer understanding of its action showed that the effect is due to an injury of the parenchyma of the liver and not to an increased capacity of the body to burn sugar. The truth is that new drugs become widely used clinically before accurate knowledge of their action is available, and continue to be used blindly long after the truth is discovered. Dr. Gold utilises facts like these to drive home to the clinician in the U.S.A. the advantages of confining his therapeutic armamentarium in the main to the non-proprietary drugs listed in the book called "Useful Drugs," published by the Council on Pharmacy and Chemistry of the American Medical Association. For those wishing to give proprietary substances a clinical trial, he suggests they should confine themselves to drugs which are listed in the book entitled "New and Non-Official Remedies," published by the same Council. This work is well known in this country as well as in the U.S.A., but for those to whom it is unfamiliar Dr. Gold explains its scope. He says:

> "If a new drug is not described there or is found in the list of preparations considered but rejected, one can rest assured that the claims made for that preparation have not been substantiated by evidence that can be considered satisfactory to authorities of that subject. There are some exceptions in which preparations are rejected because they fail in other respects to comply with the rules of the Council of the American Medical Association. When a new preparation is submitted, the Council makes a careful analysis of the evidence presented to support the claims. The character of the investigation varies with the nature of the product and the claims that are made. In many cases chemical analyses are performed and pharmacological and clinical studies carried out by disinterested workers under the auspices of the Council for the purpose of checking the evidence. In most instances," says Dr. Gold, "it becomes necessary for the manufacturer to reduce his claims to conform with the results of these additional investigations, the findings of which are usually far less optimistic than the original claims."

The Council on Pharmacy, it seems, goes a little further than our newly appointed Therapeutic Trials Committee, which proposes to examine new products only on the application of commercial firms. No attempt however is made by the Council to dictate to the doctor what he is to use in his practice. The products accepted are not even recommended. All that is attempted is to aid the physician in doing what he is trying to do himself, but without adequate facilities—namely, to separate the great mass of unofficial medicines into two distinct groups, those with valid claims and those with claims which cannot be substantiated. There is, for example, no class of drugs in which it is more difficult for him to get at the truth than in the case of the barbituric acid hypnotics. It is about 30 years ago since veronal was introduced into practice, to be followed in the intervening years by a whole series of other derivatives of barbituric acid. The claims usually made for these hypnotics are that they are more effective therapeutically, and that they are safer than veronal. Yet, according to Dr. Gold, if these are tested by the "blind test," so as to exclude the influence of subjective factors, it appears fairly certain that the therapeutic and the toxic actions of the various members of this group run essentially parallel, and that whenever the chemical structure of barbituric acid has been changed so as to increase the hypnotic action, the intensity of the toxic action has been increased to practically the same degree. It follows therefore that if the various members of this group of drugs are given in doses comparable in terms of their relative potency, they have approximately the same safety and the same therapeutic efficiency. Nevertheless there remains more in the philosophy of therapeutics than is dreamt of in the most accurately compiled list of preparations whose potency is proven to the satisfaction of any school of pharmacology.

RECENT WORK ON EPILEPSY.

Epilepsy may or may not be a metabolic dyscrasia, as J. S. Collier has asserted, but its course can undoubtedly be influenced by metabolic factors. By starvation, by ketosis, or by dehydration epileptic fits may often be greatly reduced in number, and sometimes completely arrested. N. P. Walker and G. A. Wheeler[1] now claim a similar result from yet another metabolic manœuvre—namely, elimination of the pellagra-preventive factor from the diet. This was suggested by symptoms of pellagra in a patient on the ketogenic diet, the appearance of such symptoms being accompanied by a marked decrease in the number of fits. Ten chronic epileptics, all with considerable mental deterioration, were placed on a diet well balanced in all respects except that the pellagra-preventive factors were absent, or only present in very small quantities. After a varying period, averaging about four months, stomatitis and typical skin eruptions appeared. When the symptoms became severe, treatment by yeast was instituted, and readily caused their disappearance. Fit records show that about the time the pellagra symptoms appeared there was, in most of the cases, reduction of about 50 per cent. in the number of attacks. The reason for the reduction must at present be a matter for conjecture, but the observation may prove another useful piece of ammunition for those who are seeking to attack epilepsy on its metabolic side. For obvious reasons, the method is not suitable for ordinary practice.

The theory that epilepsy is often the result of accumulations of cerebro-spinal fluid, whose drainage is impeded by pathological processes in the Pacchionian bodies, we owe to Temple Fay. Much of his work is based on encephalographic studies. Other observers, however, have taken encephalograms of epileptics with less consistent results, and in the absence of a series of encephalograms of normal people, there is no substantial agreement as to what constitutes a normal picture. J. Notkin,[2] after studying 17 female patients who were suffering from idiopathic (cryptogenic) epilepsy, claims that a dilated ventricle and a large accumulation of air in the subarachnoid spaces must be regarded as pathological. In his method all the fluid that could readily be drained off by lumbar puncture was removed and replaced by air; the amount varied from 75 to 155 c.cm. After this an X ray appearance that he considered normal was obtained in eight cases; and in these most of the air had disappeared within 24 hours. In four cases there was pronounced dilatation of the ventricles and subarachnoid spaces, especially in the region of the Pacchionian bodies, and repeated pictures showed persistence of the air, in one case up to 216 hours later—a phenomenon which Notkin is inclined to associate with the ventricle dilatation. In the five remaining cases there was evidence of other pathological changes, such as asymmetry of the ventricles or leptomeningitic adhesions, pointing to inflammatory, or possibly neoplastic, processes, which were apparently not active. It is probable that further study along these lines would lead to results of high value; and this indeed is indicated in the consequent successful therapy claimed by Temple Fay. But a procedure such that no one has so far attempted to apply it to a series of healthy people should be approached with caution. Notkin is careful to inform us that none of the patients died as a consequence of the procedure; but one died five weeks later from a severe convulsion, and another eight weeks later from an unexplained hæmoptysis. All the patients had severe headaches for 48 hours after the operation, together with rigidity of the neck, profuse perspiration, vomiting, and tachycardia, which subsequently gave place to a pronounced slowing of the pulse. He is inclined to think that some of these symptoms might be obviated if the volume of air introduced were rather less than that of the fluid withdrawn.

INFANT DEATHS AND VITAMIN STARVATION

THE North Kensington Medical Society has circulated among its members an analysis of the causes of the 180 deaths of infants under one year which occurred in the borough during the year 1928. The report is the work of three practitioners, Dr. H. E. Barrett, Dr. A. Keith Gibson, and Dr. Eleanor M. Reece, and their conclusions are worthy of close scrutiny, as they differ appreciably from those usually reached in an inquiry of this kind. In each case investigated an attempt was made to classify the various environmental factors as "good," "fair," or "bad," these factors including housing, income, antenatal and postnatal maternal employment, feeding, maternal care, foster care, size of family, and the proximity of open spaces. In nearly 40 per cent. of the cases the family income was unsatisfactory, and an analysis of other factors in the group, taken as a whole, showed that environment deteriorated in direct proportion to the decrease of family income. In homes where the income was small, therefore, they assume that death was probably the result of several unsuitable environmental factors, or, in other words, that poverty was the real cause behind a number of these deaths. It was found, however, that bronchitis and broncho-pneumonia were *no* respecters either of houses or incomes. Among the children between six months and a year in age who died as a result of these respiratory diseases it was found that a large proportion had shown signs of rickets. The incidence of breast-feeding in this group, however, was high; out of 55 deaths from respiratory infections 30 infants were completely and 18 partially breast-fed. The investigators point out that those foods which contain vitamin D also contain vitamin A, and that a child who is showing signs of rickets must therefore be receiving a diet deficient in both these vitamins. Recent experiments on the resistance conferred against infection by vitamin A lead them to conclude that a deficiency of this vitamin would be sufficient to account for the occurrence of broncho-pneumonia associated with rickets in children between 6 and 12 months old. Even during the period from the second to the sixth month they consider a deficient diet may be responsible for deaths from respiratory infections, and claim that great improvement has been seen in cases of bronchitis and broncho-pneumonia when vitamin preparations have been administered along with the ordinary remedies. Deaths under one month from these conditions may be due, they suggest, to an innate tendency to infection, due to faulty diet and environment of the mother during pregnancy. Anticipating that the high proportion of breast-feeding in this group may be quoted as an argument against their theory, the investigators point out that it is now well established that the quality of breast milk and its vitamin content depend on the food of the mother; any deficiency in her diet will be reflected in the diet of the infant. It is admittedly by no means rare to find well-established rickets in a breast-fed infant. They make the bold suggestion that in many cases a good brand of dried milk may be better for the infant than breast milk of the quality it is receiving. Inquiry into deaths due to causes other than respiratory disease seemed to show that most of the marasmus and some of the enteritis and prematurity cases occurred where the environment was bad, and that often the parents of those infants appeared to be of poor stock, with little physical or mental ability. The investigators suggest a series of simple experiments on infant and maternal feeding which might be carried out at welfare centres, to decide how far the customary diet of pregnant and nursing women is complete in those materials essential to the child.

FRIEDMANN'S TURTLE VACCINE.

EVER since its first appearance in Germany the Friedmann turtle tubercle vaccine[1] has been a trial to the serious worker in the immunological field. It has produced a large mass of clinical records, called forth at least one government report, stimulated the appearance of a competing vaccine made from a rival strain (the Piorkowsky bacillus), and finally produced a lawsuit. But in spite of all this publicity, inquiries into the purely biological properties of the bacillus have never been as thorough as they might have been. M. A. Saenz[2] has at last removed this reproach by making—we hope once and for all—a detailed investigation. The organism was first isolated by Friedmann in 1903 from the lungs of two sea-turtles captured off Italy and removed to the Berlin aquarium. Since its isolation it has undergone many vicissitudes and, as always with a strain passed from laboratory to laboratory, the purity of culture has frequently been called in question. Sea-turtles with pulmonary tuberculosis do not come the way of bacteriologists every day in the week, and laboratories have been unable, therefore, to check the original findings. Saenz has made a careful study of three cultures of the bacillus which he has obtained, and in the *Annales* of the Pasteur Institute sets forth in full detail the morphological characters, cultural properties, and pathogenic action of the organism.

[2] Bull. Acad. de Méd., 1931, cv., 853; Ann. Inst. Pasteur, July, 1931, p. 4.

He concludes that the pathogenic action of the turtle bacillus for the usual laboratory animals is limited to benign local lesions analogous to those produced by strains of saprophytic acid-fast bacilli. A tuberculin prepared from the bacillus was of very weak toxicity, and an antigen prepared after the manner of Boquet and Nègre showed only the properties of other antigens of acid-fast saprophytes. A vaccine made from the bacillus possessed neither prophylactic nor curative properties when tested in laboratory animals. This effect of the vaccine is even more discouraging than the clinical results reported a year ago by W. C. Fowler[3] in a short series of cases at Pinewood Sanatorium, and there seems to be little doubt that the acid-fast saprophyte will not perform the immunising functions of the true tubercle bacillus. Unfortunately, the exponents of the vaccine are not always ready to believe that Friedmann's bacillus is really nothing more than an acid-fast saprophyte.

ROUTINE MEDICAL EXAMINATION OF UNIVERSITY STUDENTS.

In a communication lately published by the Office International d'Hygiène Publique, an account is given of an experiment in preventive medicine carried out at the University of Strasbourg on the initiative and with the pecuniary aid of the Comité National d'Études Sociales et Politiques. The experiment was begun in May, 1929, and among the 66 first-year medical students examined some were found to be suffering from ailments which had been overlooked. This initial success led to further developments in the scholastic year 1929–30, when quite an elaborate system of examinations was devised, with as many as five different attendances: one for a general examination, including measurements of height, weight, blood pressure, &c.; one for an examination of the bones, muscles, and nervous system; a third for the eyes; a fourth for the ears, nose, and throat; a fifth for the teeth. These examinations, carried out by 16 doctors and one dentist, were timed so as not to interfere with the classes of the students. Of 861 first-year students, 406 voluntarily undertook to run the gauntlet of all five examinations. It was found, however, that the attendances at the last three examinations began to fall off, several of the students finding that the first two clinical examinations satisfied their requirements. This experience has led to the reduction of the number of attendances or examinations from five to two, and to putting the special examinations before the general clinical examination. The tabulated findings obtained by this system of combing out are already quite impressive. There were seven cases of pulmonary tuberculosis, five of which had hitherto been overlooked, and 77 cases of cicatricial lesions of the pleura, lungs, or bronchial glands, in 22 of which future periodic supervision was considered necessary. There were eight cases of organic and seven cases of functional disease of the heart requiring special precautions, and eight cases of appendicitis, most of them discovered for the first time. There were also as many as six cases of hyperthyroidism. The ophthalmic examination revealed errors of refraction in 136 cases, in 41 of which they had been overlooked or badly corrected. The tonsils and nasopharynx were found to be in a septic state in 23 students, and among the 259 who submitted themselves to a dental examination there were as many as 198 with neglected dental ailments.

It is probable, we learn, that the example of Strasbourg will soon be followed by the Cité Universitaire of Paris.

THE VIRUS OF MUMPS.

As long ago as 1908 S. Granata produced evidence that the causal agent of mumps belonged to the group of filtrable viruses, and since that time the investigations of C. Nicolle and E. Conseil (1913), M. H. Gordon[1] and M. Wollstein[2] have confirmed and extended this observation. It is true that serial passage in experimental animals was difficult to obtain; in fact, Wollstein alone was successful in this direction, and even she found that the virus soon diminished in virulence and eventually died out. Nevertheless these investigations had this in their favour, that the experimental disease resembled the human one. The more recent claim of Y. Kermorgant,[3] that the virus of mumps is a spirochæte with a filtrable phase, does not carry conviction, and has not been confirmed. F. F. Tang[4] now produces evidence of having obtained yet another virus from mumps. This came, apparently, from the saliva of an adult on the third day of disease, and was capable of passing through a Berkefeld V. candle. It was pathogenic for the guinea-pig, but not for the rabbit or cat—a fact not in keeping with the work of earlier investigators. But the dissimilarity of Tang's work and those of his predecessors in this field does not end there. The disease produced in guinea-pigs by his virus bore no resemblance to mumps. It was characterised by hæmorrhages in the subcutaneous tissues and muscles of the extremities, particularly about the joints, in the lungs, and around the costochondral junctions; and it was highly lethal, for the guinea-pig at any rate, when first isolated. Tang further admits that about the time when these transmission experiments were being made an epizoötic broke out amongst his normal guinea-pigs, the pathological picture of which bore a striking resemblance to that produced by his mumps virus. He was, however, unable to transmit this spontaneous disease, and he got some evidence that the condition might be due to an organism resembling *Bacillus bronchisepticus*. Despite this, it would appear more than probable that Tang was dealing with an extraneous virus, and not the virus of mumps.

BIRTHS AND DEATHS IN SOUTH AUSTRALIA.

In many respects the latest returns from the State of South Australia[5] show vital indices with which western Europe is familiar—for example, a birth-rate declining more rapidly than the death-rate, a corresponding decline in the rate of natural increase of population, and considerable reduction in the mortality from tuberculosis, but an increased loss from cancer. Both the birth-rate (17·2 per 1000) and the crude death-rate (8·4 per 1000) were in 1930 the lowest in the records of the State. For many years South Australia, in common with the other

[5] Statistical Register of the State of South Australia, 1930-31. Part II. Population and Vital. Compiled from official records by W. C. Johnston, F.S.S., Government Statist and Registrar-General of Births, &c.

States of the Commonwealth and New Zealand, has had a very low mortality-rate for infants under one year of age, compared with other countries. In 1930 it was as low as 48 per 1000 live births. The annual mean death-rate of infants under one year of age for the five years 1895–1899 was 110, and for the five years 1925–1929 only 47—a fall of 63. Almost the whole of this improvement is shown to have taken place at ages above one month and under 12 months. The death-rates under one month, under one week, and under one day of age show very little progress and the great majority of those dying under one month of age died from prenatal causes. These facts are, again, comparable with those of this country, and indicate the direction in which efforts for the saving of infant life should be directed. The Mothers' and Babies' Health Association, of which there are 44 branches in the State, is endeavouring to improve the position.

Over half the population are resident in the "metropolis," defined as an area approximately within a ten-mile radius of the General Post Office, Adelaide, and roughly equal proportions of the working population are employed in agricultural and industrial occupations.

PENETRATION OF DRUGS INTO THE TUBERCLE.

It has long been held that the tubercle is so avascular a structure as to be inaccessible, at all events in its caseating centre, to substances injected into the circulating blood. Intra vitam staining methods of investigation are however throwing doubt on this conviction. In a series of articles which appeared in the *Journal of Experimental Medicine*, and are now reprinted,[1] Dr. V. and Dr. M. F. Menkin show that a dye injected intravenously rapidly enters the inflamed area and is fixed there so that it fails to reach the regional lymph-node. By means of a colorimetric comparator, the authors have been able to study and record inflammatory reactions as produced in the peritoneal cavity of frogs which had been injected intra vitam with dyes after having had a sterile inflammation induced with aleuronat or turpentine. It was found that the rate of fall of concentration of the dye was almost twice as great in the capillaries of the inflamed as in those of the normal mesentery. In other words, there was an increased passage of the dye through the capillary wall in the inflamed area. Continuing these researches Dr. V. Menkin found that colloidal iron or ferric chloride, when injected into the inflamed peritoneal cavity, was fixed in the cavity and failed to reach the retrosternal lymphatic nodes, whereas, in the absence of inflammation, the iron accumulated in the nodes. These lymphatic nodes in animals with normal peritoneal cavities contained approximately 56 per cent. more iron than did the nodes of animals with inflamed cavities. He further demonstrated that ferric chloride injected into the circulating blood entered an inflamed area in the skin and that the amount of iron in the inflamed areas was much greater than that found in inflamed areas of animals that had received no iron. Dr. Menkin also found that horse serum injected into an inflamed peritoneal cavity penetrated into the blood stream less rapidly than when injected into a normal cavity. Such accumulation of foreign protein, he believes, explains the phenomenon of local anaphylaxis described by Auer in rabbits sensitised to horse serum. For instance, the antigen accumulating in the inflamed ear reacts with antibody, intensifying a pre-existing inflammatory reaction and finally producing necrosis of the ear. In the third article Dr. Menkin records some results of injecting iron into the circulating blood stream in tuberculosis. Rabbits with extensive bovine tuberculosis were given daily intravenous injections of a 0·25 per cent. solution of ferric chloride. Using the Prussian blue reaction, the author found that the blue colour became intense in the caseous or central part of the tubercle. This result however appeared to depend on the activity of the circulation, for the dye which penetrated from the blood stream into the periphery of an inflamed area failed to enter a central part in which the circulation was relatively inactive. Further work is being done to determine the effect of the accumulation of iron in tuberculous areas on the course of development of the disease. Its bearing upon the clinical value of chemotherapy is obvious.

LADY OSLER.

A brief memoir of Lady Osler, whose companionship of her famous husband made of her a famous woman, has been written by Mr. Arnold Muirhead, for private circulation. Grace Revere was of Huguenot blood; the Rivoires having fled from France to Guernsey on the revocation of the Edict of Nantes, one of them migrated to Boston and became the ancestor of Paul Revere, the patriot-metallurgist. This was Lady Osler's great-grandfather. She married, when little over twenty years of age, Dr. Samuel Gross, a Philadelphia physician, and much her senior, and their house soon became a centre of hospitality, foreshadowing the famous "Open Arms" at Oxford thirty years later. The marriage lasted thirteen years only, and when Dr. Gross died his widow was still a young woman. In 1892 she married William Osler, a devoted friend of her first husband, and it was at her instance that Osler decided to accept the chair of medicine at Oxford in 1905, after holding for 13 years the professorship at Baltimore. How she helped him in his new career has become a legend illustrative of conjugal harmony, and Mr. Muirhead's notes make us understand the wide affection which she inspired in Osler's enormous circle of friends. The battlefield deprived them of their only son, and grief contributed as much as overwork to William Osler's death not long after the struggle had ceased. But Lady Osler continued for nine years to distribute the hospitality of 13, Norham-gardens (The Open Arms), to retain the affections of old friends and gain that of new ones, and fill her days in discharge of duties to which the memory of William Osler called her. This unpretentious little memoir will bring pleasure to many.

PLACENTAL HORMONE AND UTERINE HÆMORRHAGE.

The effects of injection of the "anterior pituitary-like hormone" of the human placenta in cases of menorrhagia and metrorrhagia are reported by A. D. Campbell and J. D. Collip.[1] Forty cases were treated with an extract containing 40-day rat units per c.cm., and the dosage employed varied from 1–2 c.cm., injected subcutaneously daily or every other day, over different periods. From their results the authors gained the impression that in menorrhagia of the simpler types treatment for one week before the menstrual period materially reduces the flow, but more severe cases may require treatment for three months or longer before normal periods are established. In metrorrhagia, when the continuous uterine bleeding had been in a measure controlled, the same tendency to the establishment of normal cycles was not observed; also, intervals of amenorrhœa were apt to appear in such cases. Severe pain occurring during a period subsequent to the institution of treatment may be of favourable prognostic value, and it was noted that the duration of treatment was sometimes considerably shortened in cases where gentle curettage had recently been performed. The histological picture of the endometrium obtained by curettage does not necessarily reflect the clinical symptoms. Since the action of this and other hormones is not fully understood, the exact manner in which an active principle of placental origin may restore normal function in a case of excessive menstrual bleeding cannot at present be explained. In certain of the patients treated, cycles dated from a period of metrostaxis of one to five days' duration, occurring 10 to 18 days after the onset of the previous period of excessive uterine bleeding. No enlargement or engorgement of the breast was observed in any of the cases under treatment.

INDUSTRIAL MEDICINE AT GENEVA.

THE sixth International Congress on Industrial Accidents and Diseases, which met at Geneva in the first week of August, was a reunion of the two sections which on the last occasion met, one at Buda-Pesth, the other at Lyons. In future the Congress will combine the two branches of the subject; the next will be held in 1935 at Brussels. One of the best group of papers dealt with skin affections due to work. This subject was introduced by Dr. Prosser White, who put forward certain basic principles determining the action of skin irritants which he classified as: (1) direct, injuring by physico-chemical activity; (2) secondary, causing inflammation by stimulating sensory nerves; and (3) indirect, setting up allergy in sensitive persons. He was followed by Prof. M. Oppenheim (Vienna), who exhibited a fine series of illustrations, and Prof. F. Koelsch (Munich), who mainly considered the compensation aspect of trade dermatitis. Other subjects dealt with were the influence of previous health on accidents and industrial diseases, injuries of the blood-vessels, dust of cement and artificial stones, the reaction of the body to industrial poisons, activity and fatigue. Contributions from France, Belgium, and Germany confirmed the comparatively harmless nature of cement dust, previously claimed by American and English observers. A summary of our knowledge on industrial fatigue was communicated by Dr. H. M. Vernon, who presented the influence of occupational environment as elucidated by the Industrial Health Research Board. The papers contributed to the Congress are to be published in full later in the year. The principle of choosing subjects for discussion was adopted at Geneva. Owing however to the acceptance of a number of independent communications, only the reporters had time to summarise their papers, and discussion had to be omitted. In future it is hoped that the chief papers will be circulated beforehand and taken as read, and that independent papers, if accepted at all, will also be taken as read. The sessions could then be devoted to useful discussions and value obtained from the coming together of experts from all over the world. Something is wrong when authorities from Australia, South Africa, the United States, Great Britain, France, Germany, Austria, Italy, Czecho-Slovakia, and other countries are present, but have no chance of exchanging views in open conclave, even though skilled interpreters are at hand to help. The undoubted success of the gathering must be attributed to personal meetings and conversations which took place outside the lecture halls.

COCKROACHES ON SHIPBOARD.

UNLESS they have voyaged in the tropics, and in wooden ships, few realise how disgusting a pest coakroaches can be—and still are, for Surgeon C. L. Williams of the U.S. Public Health Service tells us[1] that 20,000 to 50,000 cockroaches are not an unusual find in a forecastle after fumigation. Iron and steel shipbuilding has reduced their harbourage, and routine anti-rat fumigation has diminished their numbers, but their complete destruction needs a longer exposure to, or a higher concentration of hydrocyanic acid than that required for rats, if the eggs in their protecting egg-cases are to be killed. Rats succumb to 60 g. (2 oz.) of HCN solution per 1000 cub. ft. of air space, acting for two hours, but five times the quantity is needed to kill all cockroaches in the time. This concentration would be too expensive to use over the whole ship, but might be employed in the inhabited part—superstructure, pantries, galleys, and cabins—costing only an extra £2 or so. This is now done at New York on what might be called moral grounds. Immediately after the anti-rat fumigation of a ship the cockroaches are noticed to be far fewer, but in a week or two they are as many as ever, which leads the ship's population to suspect that the effect on rats is just as transient. If the cockroaches were exterminated at the same time there would be less grumbling about the rat fumigation which, whatever people say, has got to be done. A valuable section of Surgeon Williams's paper emphasises the need for pasting strips of paper over openings above or below cabin doors, and over all cracks found, in order to prevent the loss of so easily diffusible a gas as hydrocyanic acid during the period of fumigation; otherwise half of it may be wasted. With the use of a higher percentage of so dangerous a gas the subsequent ventilation of the ship requires greater care. Chloropicrin, the warning gas which is sometimes added to increase safety, is not more deadly to cockroaches, although they do not, as was once feared, take advantage of the warning to secure more effectual cover. All seafarers will be grateful to Surgeon Williams for information in helping them to get quit of a pest.

---

[1] Public Health Reports, Washington, July 17th, p. 1680.

POOR-LAW HOSPITALS AND SWEEPSTAKES.—Our Dublin correspondent informs us that a circular letter has been issued by the Department of Local Government and Public Health to the authorities in control of rate-supported hospitals, dealing with their position in regard to sweepstakes. It is stated that one section of the Act imposes on the Minister the duty of applying money received from sweepstakes toward the provision, improvement, or equipment of institutions for the prevention, treatment, or cure of physical or mental diseases, or injuries to human beings. Moreover, it is expressly provided that money so applied should be in addition to, and not in substitution for, or toward, ordinary maintenance, and should not be taken into consideration by the local authority when determining the amount to be expended by them. Decisions with regard to the application of the money cannot be made until the exact amount to be distributed is known, but in the meantime the Minister invites local authorities that intend to provide, improve, or equip an institution and apply for a grant out of the money to be paid to the Minister, to take the matter into consideration and transmit their proposals to the Department.

SPECIAL ARTICLES

EXPERIMENTAL OBSERVATIONS ON DERMATITIS DUE TO DYED FUR.

By G. H. Percival, M.B., Ph.D., F.R.C.P. Edin.,*
ASSISTANT PHYSICIAN TO THE SKIN DEPARTMENT, ROYAL INFIRMARY, EDINBURGH.

(From the Skin Department of the Royal Infirmary and the Pharmacology Department of Edinburgh University.)

In the winter of 1922–23 it became apparent that the incidence of cases of dermatitis due to the wearing of dyed fur had suddenly increased. Before that period dyed fur had been recognised as a cause of dermatitis, both among those engaged in the preparation of such articles and among those wearing them, but, nevertheless, examples of this type of eruption were rarely seen. The increase noted in 1922–23 was maintained during the winter of 1924, and during these years several papers dealing with the subject were published. In 1924 the Ministry of Health conducted an inquiry into the occurrence of dermatitis attributed to the wearing of fur collars. The main conclusions arrived at in the report of the Ministry[1] (which were based on facts obtained during the inquiry and on papers dealing with the subject in the current medical journals) were as follows: Personal idiosyncrasy on the part of the patient was responsible to some extent for the appearance of the dermatitis, but this susceptibility was specific for a certain class of fur, and did not explain the sudden and unprecedented incidence of fur dermatitis cases. The dermatitis was apparently produced by products of the incomplete oxidation of para- and meta-phenylenediamine. In some instances the mordant used was also thought to be partly responsible. The part played by personal idiosyncrasy was obvious when the proportion of sufferers from fur dermatitis to wearers of dyed furs was considered. The facts recorded in the inquiry did not, however, provide any conclusive evidence as to the nature of the actual constituent in the fur which was responsible for the dermatitis, and any statements regarding this important point were merely tentative. During the process of dyeing, a fur may be treated with various chemicals, including the actual dye itself, and any one of these is theoretically a potential skin irritant. The fact that a particular or even chemically unidentifiable oxidation product of an aniline dye can be isolated from a fur which is known to have been treated with the mother substance of the isolated compound is no proof that such a compound is the cause of the dermatitis which the fur has produced. Direct proof of the specific irritant properties of a substance on the human skin can only be obtained from biological experiments with the substance in question. A more precise knowledge of the nature of the specific susceptibility of the skin towards the irritant may also be obtained if such methods are employed in the investigation of the problem.

Cases of dermatitis due to dyed fur, although less numerous than in the years 1922–24, are still frequently met with. Table I. shows the total number such cases and their percentage of the total number of cases of dermatitis in females over 15 years of age who have been treated in the skin department of the Edinburgh Royal Infirmary during the decennium 1920–30 :—

TABLE I.

A = Total number of cases of dermatitis in females over 15.
B = Number of cases due to fur.
C = Percentage of total due to fur.

Year.	A.	B.	C.	Year.	A.	B.	C.
1920	174	1	0·57	1926	238	16	6·72
1921	185	1	0·54	1927	168	7	4·18
1922	135	1	0·73	1928	252	13	5·15
1923	194	22	11·34	1929	362	23	6·35
1924	233	37	15·88	1930	385	13	3·37
1925	201	17	8·45				

For obvious reasons, the complaint is almost exclusively met with in females, so that figures dealing only with dermatitis in females have been given for the total annual number of dermatitis cases in the Table. As no cases of fur dermatitis have been met with in young children, the numbers given for all classes of dermatitis have been limited to cases over 15 years of age. The number of cases of fur dermatitis given for 1920–22 may be slightly low, since attention was not concentrated on the possibility of fur being the cause of dermatitis until the condition became prevalent in 1923. Nevertheless, the abrupt rise in 1923–24 is undoubtedly real, for the numbers were then much higher than in the succeeding years, during which the condition was well recognised.

Since the incidence of this type of eruption is still considerable, an investigation into its causation and nature has been undertaken. Furthermore, as the problem involved was a concise one, dealing with a type of dermatitis due to an irritant which could presumably be definitely ascertained, it was thought that any observations which might be made during the course of the investigation would have some bearing on the related problems presented by other types of dermatitis, either due to external or internal causes.

Investigation.

The irritant properties of two lambskin furs, one dyed brown and the other grey, which were known to have caused dermatitis, were examined. The experiments carried out with the brown fur were of a preliminary nature to test out the methods which it was proposed to use throughout the investigation, while those performed with the grey fur were more detailed, and were pursued further.

The main issues of the problem may be stated as follows :—

(1) Is the skin irritation produced by a dyed fur due to the fur itself or to the chemicals used in the dyeing process ?

(2) Are any special conditions, such as moisture or a greasy skin, necessary before a dyed fur can produce skin irritation, and, if so, will apparently normal skins react to certain dyed furs provided such favourable conditions are present ?

(3) Can a skin, which has previously tolerated a given fur, subsequently develop an eruption when again brought into contact with this fur ?

(4) What substance in the fur is responsible for the production of dermatitis ?

(5) What concentration of this substance is required in order to produce dermatitis ?

(6) Does the action of the irritant substance, when this is present in the concentration required to produce dermatitis, differ on normal skins and on the

---

* In receipt of a part-time grant from the Medical Research Council.

skin of subjects who have suffered from dermatitis due to the particular irritant in question ? In other words, is the irritation which is produced by the substance entirely due to a constant specific pharmacological action depending on and proportional to its concentration, or must the skin possess or develop the property of reacting to the application of the substance with a special type of reaction before the latter can produce any harmful effects ?

(7) If such a qualitative difference does exist between normal skins and those which are irritated by compounds contained in dyed fur, what is the degree of this difference ?

(8) Can the irritant properties exhibited by a given dyed fur be removed by appropriate chemical or physical manipulation ?

The method used throughout in the investigation of these questions was that of the contact eczema test.

This test was introduced by Jadassohn and Bloch to detect the external irritant in cases of dermatitis, and since its introduction it has been extensively used on the continent as a routine practice in the investigation of such cases, and in special investigations on the nature of dermatitis. The method is simple, and consists in the application of the suspected irritant in low concentration, either in solution, paste, or ointment form, to a small area of the skin of the back. Solutions are applied as soaks on small linen squares. The test application is covered with linen or oiled silk and kept in position with adhesive plaster. The application is removed at the end of 24 hours, and the skin examined. If the test is positive, the skin which has been in contact with the test substance is red and slightly œdematous, and the surface is studded with minute vesicles. It presents the appearance of a localised area of dermatitis. The area in direct contact with the adhesive plaster is frequently red and the hair follicles prominent, but this quickly subsides, although in some cases the skin is actually sensitive to the ingredients of the plaster, and the redness persists. Sometimes a positive reaction is not evident when the tests are removed and the skin examined at the end of 24 hours, but develops during the succeeding 24 hours. It is necessary, therefore, to verify all negative reactions 24 hours after removal of the test applications, in case a late positive reaction develops. A positive result is a direct proof that the substance applied is capable of producing a dermatitis in the concentration employed, and the degree of sensitivity of the skin towards the substance can be ascertained by varying the concentration of the latter.

While such tests are of immense value in elucidating the cause of individual cases of dermatitis, they have also been used to demonstrate the relative susceptibility of the skin of patients suffering from dermatitis to react to several types of irritants, as compared with the skin of normal individuals. Thus Jaeger[2] found that 50 per cent. of cases of dermatitis gave an abnormal inflammatory reaction to certain volatile oils, while only 5 per cent. of normal individuals reacted. Using similar substances, Bloch[3] found that 35 per cent. of the dermatitis cases reacted, and only 5 per cent. of normal individuals gave positive reactions. Evening[4] obtained positive results in 36 per cent. of dermatitis cases, and 2·2 per cent. of normal individuals, and Schürch[5] obtained results of a similar order.

BROWN LAMBSKIN DYED WITH PARAPHENYLENEDIAMINE.

The first fur to be investigated, using this method, was a brown lambskin which had been dyed with paraphenylenediamine. Three female patients, who were known to have suffered from dermatitis of the neck, due to the wearing of dyed fur collars, were tested. In each case the rôle of the collar in the production of the dermatitis had been proved on several occasions by its disappearance when the fur ceased to be worn, and its subsequent reappearance on the reapplication of the fur to the neck. Three tests were made in each of the three cases, using the patient's own fur, the brown lambskin and undyed lambskin. Portions of the furs were clipped off the skins, and three applications were made with each fur, a sample of each fur being applied dry, moistened with distilled water, and moistened with saline. The tests were removed and read at the end of 24 hours, and again at the end of a further 24 hours. The results are given in Table II.

TABLE II.

Results of contact tests with paraphenylenediamine-dyed brown lambskin fur applied for 24 hours in three patients who had suffered from dermatitis due to dyed fur collars.

2	+ + +	+ + +	+ + +	+ +	+ + +	+ + +	–	–	–
3	+	+ + +	+ + +	+	+ + +	+ + +	–	–	–

+ = redness persisting for 24 hours.
+ + = redness and œdema.
+ + + = redness, œdema, and minute vesiculation of the surface, and itching.
+ + + + = redness, marked œdema, and vesiculation of the surface and itching.

The positive reactions to a single application of the dyed furs persisted for 10 to 15 days, passing through a dry scaly stage before the skin resumed its normal appearance.

It is evident from these results that the irritant properties of the dyed lambskin are due to one or more of the constituents used in the dyeing process. It has also been shown that moistening the fur with either distilled water or saline solution increases its irritant properties, although it is to be noted that preliminary moistening is not necessary for the production of a positive reaction. In all cases the patient's own fur and the dyed brown lambskin fur caused some staining of the skin, even when applied in the dry state, and this staining was due to some of the dye becoming dissolved either in the moistening fluids or in the perspiration or oily secretion of the skin. Case 2 had a coarse, greasy skin, and in her the dry applications caused more staining than in Cases 1 and 3. The fact that the reactions to the dry furs were less marked than those to the moist preparations suggests that the concentration of dissolved dye bears a direct relationship to the intensity of the reaction which it produces.

To control these observations, the brown lambskin fur was applied dry, moistened with distilled water, and with saline, to the skin of 15 patients suffering from various types of skin diseases. The patients were retested with similar applications after an interval of 16 days to verify the results of the first tests and to ascertain whether it was possible for a skin which had shown a negative reaction to the first application to develop an altered reaction as a result of this application, so that a positive reaction would be given to subsequent tests. The results are given in Table III.

The fur did not produce a positive reaction in these patients when applied for the first time. In most of these cases all the fur applications produced some degree of staining of the skin, and in several the skin was excessively greasy. This staining is well shown in Fig. 1. It may therefore be concluded that normal skins do not tend to react to the dye dissolved from the brown lambskin fur, even when this substance is in prolonged contact with the skin, either in watery or oily solution. One case, however, developed a positive reaction to all three applications of the fur on testing a second time, although the results of the first test had been negative. This patient's skin apparently developed a susceptibility towards some substance in the fur, and presumably the altered reaction which occurred had been brought about as a result of the first application.

TABLE III.

Results of tests with brown lambskin fur in 15 patients suffering from various types of skin disease. The fur was applied dry, moistened with distilled water, and with 0·9 per cent. saline. Each patient was retested after an interval of 16 days.

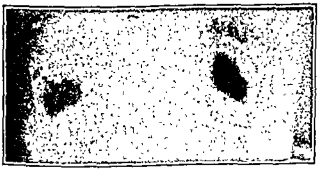
Pos.=positives; Neg.=negatives.

These preliminary experiments show that the skin of patients who are the subjects of fur dermatitis reacts differently from that of normal individuals to the application of a dyed fur which possesses irritant properties, even when the conditions favourable to the production of a dermatitis reaction are equal in both types of individual. They also show that the skin of a patient suffering from dermatitis, due to some other cause, is not specially apt to react to dyed fur, suggesting that the constituent in the dyed fur responsible for the reaction in susceptible cases is not a universal irritant for eczematous individuals. A specific capacity on the part of the skin to react with such substances appears to be a necessary factor before any reaction takes place. This capacity bears no relationship to the oiliness or moisture of the skin, as shown by the negative reactions obtained in normal individuals in which such conditions were present to a marked degree. The experiments further demonstrate that it is apparently possible for a previously normal skin to develop a sensitivity towards dyed fur as a result of one application of the fur.

FIG. 1.



This patient's skin was greasy, and marked staining of the skin with the dye from a brown lambskin fur applied dry (left) and moistened (right) has occurred. The dry preparation has caused almost as much staining as the moist. No reaction followed either application.

EXPERIMENTS WITH GREY LAMBSKIN.

On the basis of these preliminary experiments, a further series of experiments was carried out to test the irritant properties of a grey dyed lambskin, which had been responsible for a few cases of dermatitis. This fur had undergone treatment with solutions of proprietary substances, which will be referred to as A, B, C, and D. Substance A, which belonged to that class of phenylenediamine compounds known as ursols, and which contained paraphenylenediamine, but not metaphenylenediamine, gave a purplish-grey solution when allowed to oxidise in air for several days, and when mixed with hydrogen peroxide developed a medium-grey colour. Solutions of the other substances were colourless. In the dyeing process hydrogen peroxide was used to develop the required grey colour.

Contact tests were performed with this fur in 50 patients suffering from various types of skin lesions, but with no history of previous fur dermatitis. The fur was applied moistened with distilled water, since in the preliminary experiments with the brown lambskin fur it had been shown that in fur-sensitive individuals a more intense reaction was given when the fur in question was applied moist. Each individual in the series was retested with the fur after an interval of 16 days had elapsed from the time of the first test. The results are shown in Table IV.

TABLE IV.

Results of contact tests with moistened dyed grey lambskin in 50 patients suffering from various skin lesions. The tests were repeated after an interval of 16 days.

Disease.	Cases.	First test.		Second test.	
		Pos.	Neg.	Pos.	Neg.

D. herpetiformis	1	0	1	0	1
Total	50	0	50	0	50

The results show that the fur does not contain any substance which has universally toxic properties in the concentrations obtained in the experiment. Again, staining of the skin by the fur was frequently in evidence.

Twelve patients known to have suffered previously from fur dermatitis were then tested with moist applications of the grey dyed lambskin fur. The clinical histories of those patients strongly suggested that the dermatitis from which they had suffered was due to the wearing of dyed fur; the dermatitis persisted until the fur ceased to be worn, and eczema tests with the fur afforded absolute proof of the causal relationship of the fur to the dermatitis. In some cases other types of dyed fur, which were substituted for the originally offending article, also caused dermatitis, while in others a dyed fur had been found which could be worn with impunity.

Each of these patients gave a positive reaction to the test application of the grey lambskin. In four cases the positive reaction was not evident until 24 hours after the test applications had been removed —i.e., 48 hours after their first application. The reaction was intense in every case, and consisted of redness, œdema, and minute vesiculation, and was accompanied by a considerable degree of itching. From the clinical histories of these patients it will be seen that, although the patient had suffered from dermatitis produced by a fur collar, it had been subsequently possible to obtain and to wear a dyed fur which did not produce any harmful results. This being so, the results of the tests with the grey fur might well have been negative.

The positive results obtained in these cases, when compared with the uniformly negative results found in other types of skin disease, demonstrate the existence of a special reactivity or sensitivity on the part of the skin in the former group. They also show that patients who have shown this type of sensitivity to one particular dyed fur are extremely liable to react similarly to other types of dyed furs.

Since several chemical substances had been employed in the preparation of this fur, these were tested out separately on fur dermatitis Cases 1, 2, 4, 9, and 13, and also on 50 patients suffering from various types of skin disease. The following test solutions were used:—

Solution I. = 0·5 per cent. aqueous solution of "A."
„ II. = 0·5 „ „ „ "B."
„ III. = 0·5 „ „ „ "C."
„ IV. = 0·5 „ „ „ "D."

The results in fur dermatitis cases are given in Table V.

TABLE V.

Results of contact tests with solutions I. to IV. applied for 24 hours in fur dermatitis cases.

10 ..	++++	—	—	—

Forty-nine of the 50 cases suffering from skin disease, other than fur dermatitis, gave a negative reaction to all four test solutions on the first application, and also on a second application performed after an interval of 16 days. One case gave a strong positive reaction to solution 1 (0·5 per cent. "A"), while the reactions to solutions 2, 3, and 4 were negative. This patient was suffering from a leg ulcer, and had never worn dyed fur. When tested with the grey dyed lambskin she gave a strongly positive reaction.

The above results definitely prove that the potential irritant properties possessed by the grey lambskin fur are due exclusively to the presence therein of "A," or of some decomposition or oxidation product of this substance which had developed in the 24 hours during which it was in contact with the skin. The essential part played by a specific sensitivity of the skin in the production of dermatitis has again been demonstrated, and the results obtained with the fur itself have been confirmed and more accurately defined. The specific sensitivity of the skin which is associated with the dermatitis reaction is not possessed to any extent by normal skins.

In all, 100 cases of various types of skin disease (other than fur dermatitis cases) were tested either with the grey fur or with "A," and of these only one displayed any evidence of sensitivity, whereas a positive reaction was given by all fur dermatitis cases tested. Such a reaction must, therefore, be considered as abnormal, and must depend on some defect in the skin itself.

In order to ascertain whether it was unaltered "A" or its oxidation products which were reacting with the abnormal skin, a 24-hour old mixture of 0·5 per cent. "A" solution and hydrogen peroxide was tested on fur dermatitis Cases 1, 2, 4, 9, and 10. The results are given in Table VI.

These observations show that the positive results obtained with the fur itself and with freshly prepared 0·5 per cent. "A" solution were due to the skin reacting either with unchanged "A" or with its early oxidation products, and that the more completely substance "A" was oxidised the less was the sensitised skin likely to react with it.

0·5 per cent. "A" solution + hydrogen peroxide	—	—	++	—	++

While the marked contrast between the number of positive reactions obtained in fur dermatitis cases and in non-fur dermatitis cases is strong evidence that, in the former group, the skin is hypersensitive to substance "A," it gives no indication of the degree of this hypersensitivity. The following experiments were performed in order to gain an approximate quantitative estimate of this factor. Fifty patients suffering from various types of skin disease who had previously given a negative reaction either to 0·5 per cent. "A" or to the grey lambskin fur were tested with 1 per cent., 5 per cent., and 10 per cent. solutions of "A." No positive reactions were obtained with the 1 per cent. solution, negative reactions were given by 48 patients to 5 per cent. and 10 per cent. solutions, and two cases reacted to 5 per cent. and 10 per cent. solutions. Fur dermatitis Cases 1, 4, 5, 10, 11, and 12, and the case of leg ulcer, which had given a positive reaction to 0·5 per cent. "A" and to the grey fur (Case 13) were tested with 0·5 per cent., 0·1 per cent., 0·05 per cent., and 0·005 per cent. solutions of "A" and with the grey fur. The results are shown in Table VII.

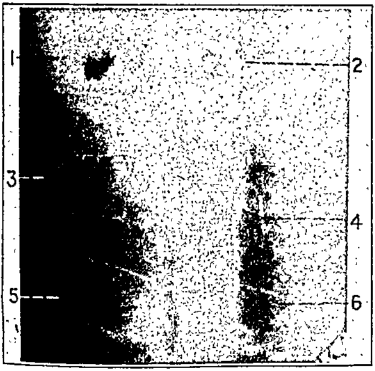
TABLE VII.

Results of contact tests with grey lambskin fur, 0·5 per cent., 0·1 per cent., 0·05 per cent., and 0·005 per cent. solutions of "A" in fur dermatitis and "A" sensitive cases.

Cases.	Fur.	Solutions of "A" (per cent.).			
		0·5	0·1	0·05	0·005
1	++++	++++	+++	+++	—
4	++++	++++	+++	+++	+
5	++++	++++	+++	—	—
10	++++	++++	+++	—	—
11	++++	++++	+++	—	—
12	++++	++++	—	—	—
13	++++	++++	++++	++++	++++

These experiments show that the difference in sensitivity to dyed fur between a skin which is intolerant to it and a normal skin is of considerable magnitude. Thus Cases 4 and 13 react to at least 1/2000 of the concentration of "A" to which a normal skin is tolerant. Case 4. Cases 5, 10, and 11, and Case 12 react, respectively, to 1/200, 1/100, and 1/20 of the same concentration. The position might be regarded from the opposite standpoint, and Cases 4 and 13 considered as being at least 2000 times, Case 4 200 times, Cases 5, 10, and 11 100 times, and Case 12 20 times as sensitive to "A" as the normal skin. Moreover, it is possible that the normal skin would tolerate concentrations of "A" higher than 1 : 10, in which case the sensitivity of the reacting skins would be correspondingly greater. When the positive reactions obtained with varying dilutions of "A" are compared with those obtained with the ursol-dyed fur, it is possible to gain some idea of the concentration of "A," which is presumably dissolved out of the fur and brought into contact with the skin to give rise to the positive skin reaction produced by the fur. In Cases 1 and 2 this must have been between 0·05 per cent. and 0·005 per cent.; in Cases 5, 10, and 11 between 0·05 per cent. and 0·1 per cent.; and in Case 12 between 0·5 per cent. and 0·1 per cent. Case 12 further demonstrates that it is possible for a solution of "A," having a concentration of at least between 0·1 per cent. and 0·5 per cent., to be formed from the grey fur when this becomes moist.

FIG. 2.



Case 6, Table VIII., tested with fur samples 1–6.

After application of test—
1 = Reaction to fur 3 .... 36 hours.
2 = " " " 2 .... 36 "
3 = " " " 1 .... 36 "
4 = " " " 4 .... 36 "
5 = " " " 5 .... 36 "
6 = " " " 6 .... 36 "

An interesting and important point, conclusively shown by the results of the tests with different concentrations of "A," is that the sensitivity of the skin in fur-sensitive cases shows wide individual variations. The results also show, although less definitely, that the intensity of the reaction in individual cases varies directly with the concentration of "A." It seems probable, however, that the range of concentrations throughout which graded reactions occur is small, and that, once a certain concentration is reached, the intensity of the reaction obtained in maximal.

THE EFFECTS OF CLEANING.

The substance in the grey fur which took part in the production of the reaction exhibited by abnormal skins when in contact with the fur having been identified as substance "A" or an early oxidation product of this substance, attempts were made to ascertain whether it could be removed by special methods. For this purpose seven samples of lambskin fur dyed with "A," but subjected to different cleaning processes, were tested on eight fur-sensitive cases, along with the original grey lambskin used in the previous experiments. The cleansing processes consisted in washing in water or benzene for varying periods, brushing, or drumming with sand. It was not possible to test out all eight samples in each case, while in some individual cases the same sample was tested on several occasions. The results are given in Table VIII.

TABLE VIII.

Results of contact tests with original "A" dyed grey fur (fur 1) and with seven grey furs dyed with compound "A," and subjected to various cleansing processes, in fur-sensitive cases.

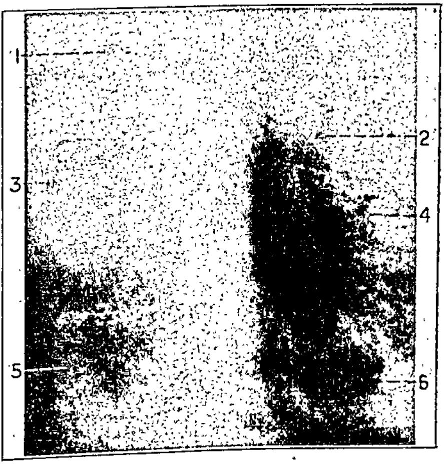
FIG. 3.



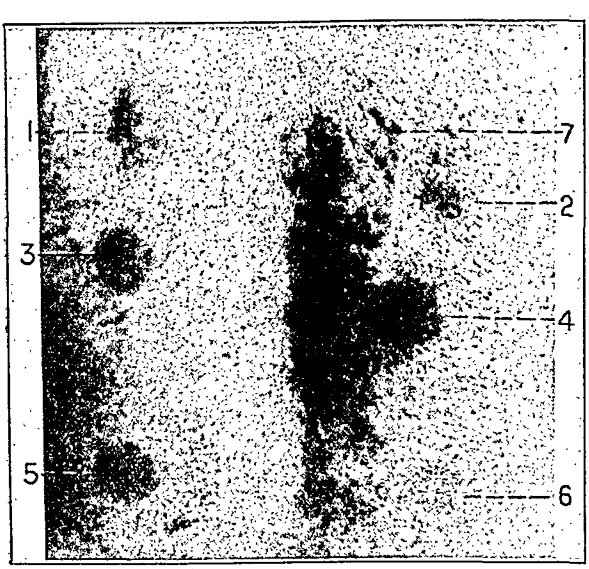
Reactions given by Case 4 to samples 1, 2, 3, 4, and 5.

After application of test—
1 = Reaction to fur 1 .... 5 days.
2 = " " " 3 .... 5 days.
3 = " " " 1 .... 30 hours.
4 = " " " 2 .... 30 "
5 = " " " 4 .... 30 "
6 = " " " 5 .... 30 "

This Table shows that with adequate cleaning methods it is possible to reduce considerably, and perhaps to eliminate altogether, the substance in the dyed fur which causes the hypersensitive skin to give a dermatitis reaction. A comparison with the reactions given by Case 4 in Tables VI. and VII. shows that any solution of "A" derived from fur 6 when in contact with the skin must have been of a lower concentration than 0·005 per cent., since Case 4 was capable of reacting to this concentration, whereas she gave no reaction to fur 6.

In this investigation the reactions given by Case 4 were of special interest. This patient was first tested with furs 1, 3, and 6. No reaction was obtained with fur 6, while a well-marked reaction occurred with fur 1, and a papulo-erythematous vesicular reaction occurred with fur 3. The reaction to fur 1 was still visible at the end of five days as a dry, pink, scaly area, but that to fur 3 had almost faded. At this time fur 1 was reapplied, together with furs 2, 4, and 5; 24 hours later the tests were read and positive results (Fig. 3) were found in each case. During the following few days a flare-up of the subsiding positive reactions to the first application of fur 1 and of fur 3 occurred. This exacerbation gradually subsided, along with the reactions to the second application of fur 1 and of furs 2, 4, and 5 during the succeeding 37 days. Twelve days after the second application of fur 1, and at a time when the reactions to this application and to furs 2, 4, and 5, and also the exacerbation of the reactions to the first application of furs 1 and 3, were subsiding, a third application of fur 1 was made. A well-marked erythemato-vesicular reaction followed (Fig. 4), but, contrary to expectations based on the experience with fur 3, there was no general flare-up of the fading reactions to furs 1, 2, 3, 4, and 5. Fifty days from the date of the first test applications the skin of the back had resumed its normal appearance. Fur 3 was again applied at this time, and a positive result was obtained at the site of application only (Fig. 5). The interesting feature of these results is the flare-up of subsiding positive reactions on one occasion, which was coincident with the application of fresh tests to adjacent areas. This point will be discussed later.

FIG. 4.



Reaction given by Case 4 to samples 1, 2, 3, 4, and 5.

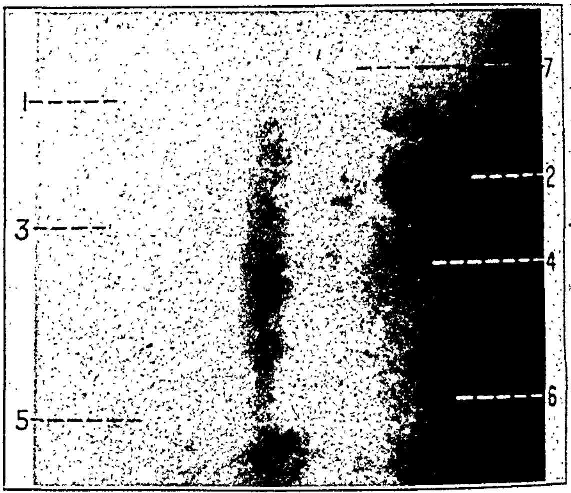
FIG. 5.



Reactions given by Case 4 to samples 1, 2, 3, 4, and 5.

1, 3, 4, 5, 6, 7 represent the corresponding sites in Figs. 2 and 3 50 days after the first tests were applied. The reactions have completely faded, leaving only a faint pigmentation of the skin.

2 = Reaction to fur 3, 36 hours after the application of the test.

ATTEMPTS TO TRANSFER SKIN SENSITIVITY TO NORMAL SKINS.

Serum was obtained from Cases 4 and 13, both of whom had shown the greatest skin hypersensitivity to "A," and 0·2 c.cm. of each sample was injected intradermally into four areas of the skin of the forearm in four individuals who had given a negative reaction to contact tests with 10 per cent. "A." After four hours the injected areas were tested with 0·5 per cent. "A" applied to a scratch and also as a contact test. (Method of Prausnitz and Küstner.) Control scratch and contact tests were made on adjacent uninjected skin. No positive reactions were obtained with any of the tests. Both forms of test were repeated 24 hours later, but again the results were negative.

SUMMARY OF THE FOREGOING EXPERIMENTAL RESULTS.

(1) The potential irritant properties of a dyed fur are due to some substance used in the dyeing process, and not to mechanical irritation by the fur.

(2) Normal skins do not react to a dyed fur even under conditions in which the fur in question would produce dermatitis in a fur dermatitis patient.

(3) The dermatitis is due to a hypersensitive skin reacting with some substance in the dyed fur in concentrations with which normal skins do not react, and, therefore, this reaction may be termed allergic.

(4) The substance in the fur investigated with

which the allergic skin reacts is "A," or an early oxidation product of this compound.

(5) Fur dermatitis cases react to concentrations of "A," varying from 0·005 per cent. to 0·5 per cent., and in these cases there is considerable individual variation with regard to the concentration necessary to produce dermatitis.

(6) Most normal skins fail to react with a 10 per cent. solution of "A" although some were found to react with a 5 per cent. solution.

(7) The degree of sensitivity of the skin to dyed fur found to exist in fur dermatitis cases ranged from at least 200 times to 2000 times that found in non-fur dermatitis cases.

(8) It is possible for at least a 0·5 per cent. solution of "A," or its oxidation products, to be formed in the fluid secretions of the skin when in contact with the dyed fur. This type and concentration of solution does not produce dermatitis in non-fur dermatitis cases.

(9) Dermatitis resulting from a single application of a minute concentration of a chemical towards which the skin is allergic may persist for several weeks.

Comment.

Two conclusions may justifiably be drawn from the results obtained in the foregoing experiments. The first is that "A" is the only factor present in the fur which takes any part in the production of dermatitis. The second, and the more important from the point of view of its general application, is that the dermatitis depends on an allergic state of the skin, and that it is idiosyncratic in nature. The term allergy is here used in its wider sense, according to the definition of Bloch, which is as follows:—

> "Allergy is that state which has as its basis the property of certain groups of cells (organs) of the living organism to react in a specific manner when brought in contact with a substance which is, as far as is known, foreign to the organ or cells; the characteristic of this specific pathologic process lies in the fact that it is caused by the reaction of this exogenous substance with its specific cellular fixed antibody. The basis and essence of allergy is the ability of the living cell to react with the production of specific antibodies to the stimulus of foreign substances, which are therefore called antigens, as well as the fact that the contact of the antigen with its specific cellular fixed antibody causes a disturbance of cellular life which usually results in an inflammatory reaction."

The term idiosyncrasy means that the reactions caused by the exogenous substances in question occur only in a small percentage of individuals. The reason for idiosyncrasy is therefore the presence of the allergic state in those individuals who are idiosyncratic. As a result of allergy, idiosyncratic individuals react to substances which produce no effect in normal individuals. Such substances are, therefore, irritant and toxic for the former class, but perfectly harmless for the latter. This toxic effect, however, is not proportional to the dose or concentration of the substance coming in contact with the cells, but is entirely dependent on the state of these cells. The substance only precipitates a reaction when the cells are in a state of allergy. Such a reaction is not due to the pharmacological action of the substance, since this would be approximately the same in all individuals, and would be proportional to the amount of the substance acting on the cells. It has been shown that allergic phenomena, which were originally considered to be brought about only by antigens of a protein nature, can be caused equally well by crystalline substances.

The results of the tests show conclusively that positive reactions occur only in idiosyncratic individuals, and that they are due to the allergic state of the skin towards "A." In this class of individual the intensity of the reaction bears no constant relationship to the concentration of "A" applied to the skin. In one case a concentration of 0·5 per cent. may be required, while in another 0·005 per cent. will suffice. The uniformly negative results obtained with 0·5 per cent. "A," and the large percentage of negative results obtained with 10 per cent. "A," in individuals who had not suffered from fur dermatitis, show that even in these strengths the pharmacological action of compound "A" cannot be described as irritant. Nevertheless, throughout the range 0·5 per cent. to 10 per cent. several positive reactions were obtained, and these individuals may be considered idiosyncratic in the same way as those sensitive to lower concentrations, but in the former case the allergy is of a less delicate or sensitive nature. It is possible that with concentrations higher than 10 per cent. compound "A" would display universal irritant properties, which would then depend on the pharmacological action of the drug, be proportional to the dose, and independent of the state of the skin in individual cases. When it is considered that reactions were obtained with concentrations from 1/200 to 1/2000, which was tolerated by normal individuals, it is obvious that some factor other than the direct action of "A" must be mainly responsible for the reaction. This factor can only be the altered state of reactivity of the skin cells, or, in other words, allergy. Apart from the evidence derived from a comparison of the active concentrations in reacting individuals and the concentrations tolerated by individuals, the behaviour of the positive reactions which were obtained denotes their allergic nature. The latent period observed between the removal of the test application and the appearance of a positive result, and the tendency for positive reactions to flare-up as a result of subsequent applications of "A," are both typical of allergic phenomena.

The results obtained by Burgess and Usher[6] are comparable to the more general findings in the present investigation. They found that of 200 normal persons tested with a face lotion which had been associated with dermatitis 0·5 per cent. gave a positive reaction, while a reaction was obtained in all patients who had suffered from the dermatitis. They record the interesting observation that in several of these dermatitis patients a positive reaction could only be obtained at the site of the healed dermatitis, so that in those cases the allergy was localised to certain skin areas. No example of regional allergy was found in the present investigation, and in every case the allergic phenomena were elicited over wide areas of skin. Beyond demonstrating the idiosyncratic and allergic nature of the disease, and proving that only one constituent of the lotion was capable of producing it, Burgess and Usher performed no experiments to demonstrate the quantitative nature of the allergy.

The fact that in the present experiments positive reactions were only obtained when "A" was applied to the intact skin, and that uniformly negative results were obtained by the scratch method, points to the allergy being localised in the epidermis. It also points to the necessity of carrying out both types of test when an allergic condition of the skin is suspected.

Attempts to demonstrate the presence of free antibodies in the serum, by the passive transference method of Prausnitz and Küstner, and so to prove the antibody-antigen nature of the positive reactions obtained in the skin, failed in three cases. Successful results, although frequent in urticaria with this method, have only rarely been obtained in cases of dermatitis. Biberstein has, however, actually demonstrated the Prausnitz-Küstner reaction in ursal dermatitis. A negative Prausnitz-Küstner reaction merely suggests that demonstrable antibodies are not present in the serum, and does not exclude the probable antigen-antibody nature of the allergic reaction of the skin cells.

The facts observed with compound "A" therefore show that any skin reaction which occurs with this substance in low concentration is due to the allergic conditions of the skin, and not to the primary irritant action of "A." There are ample opportunities for "A" present in a fur to dissolve in the secretions of the skin when the fur is brought into contact with the skin, and it is probable that the allergic skin only reacts to "A" when in solution.

The latent period observed clinically between the first time of wearing a fur and the development of dermatitis, which may amount to a few weeks, may be due to several factors. When short, it is probably a delayed reaction to the first contact with the fur, similar to that noted in the reaction to skin tests. When of longer duration, it may either be due to an initially non-allergic skin developing allergy, as has been shown to be possible in the preliminary experiments, or to the fact that in an allergic person no direct contact between the skin and the dyed fur has occurred during the first two or three occasions on which the fur has been worn.

The results obtained in the foregoing experiments suggest that similar processes are responsible for the production of dermatitis by furs dyed with other amines, diamines, aminophenols, diphenols, and their substitutes. No definite comparisons are justifiable, however, and any fur which has been associated with dermatitis must be subjected to similar biological analysis before a definite statement can be made regarding the nature and cause of the dermatitis. Chemical analysis of the fur yields no information as to its possible biological effects. It is a well-known clinical fact, and one which is illustrated by the case-histories of the fur-sensitive cases here reported, that an individual may suffer from dermatitis when wearing one dyed fur, but not another. The reason for this may be that the pre-existing or subsequently developed allergic state of the patient's skin is specific for one amine body, or that the fur which is not associated with dermatitis contains no available antigen.

It has already been pointed out that the experiments with "A" show that this substance is not, strictly speaking, an irritant, and that when signs of inflammation follow its application to the skin in an idiosyncratic person this is entirely due to the skin being in a highly intolerant or allergic state. From the series of tests carried out with "A" dyed fur and with "A" on unselected cases of skin diseases, it appears that a very small proportion of individuals exhibit an idiosyncracy to "A," and when the number of cases of fur dermatitis is compared with the total number of fur-wearers this proportion is infinitely less. Incidentally, it has been shown that the existence of various types of skin disease, other than fur dermatitis, are not associated with an unduly high proportion of individuals sensitive to "A." When several substances to which individuals are known to have shown an idiosyncrasy are compared, it is found that the number of idiosyncratic individuals varies greatly according to the substance. Thus Bloch[7] quotes experiments to show that 80 per cent. of all individuals are sensitive to ascaris, 60 per cent. to poison ivy, and 45 per cent. to orthoform. Moreover, by using concentrated extracts of primula, he has been able to produce an allergic state in the skin of 100 per cent. of persons, thus overcoming the individual constitutional factor (idiosyncrasy), and converting an idiosyncrasy into a pure allergy. These facts would have to be born in mind when assessing the extent to which any compound in a dyed fur was capable of participating in or precipitating allergic reactions of the skin.

They also have an important medico-legal bearing. First, the fundamental rôle played by allergy in such cases, and, secondly, the proportion of normal to idiosyncratic individuals ought to be considered when compensation claims arise.

MEDICINE AND THE LAW.

The Theft of Motor-cars.

In his report for 1930 the Commissioner of Police for the Metropolis has to confess that there was a 50 per cent. increase in the number of motor cars reported stolen. It is true that he can claim that recovery quickly follows in a very large percentage of cases; out of 4941 cars stolen during the year only 182 were not recovered. But this measure of success is not completely reassuring to professional men who must rely on the reasonable safety of their means of movement. No doubt, as the report says, the cars are often taken only for pleasure rides. Here it is satisfactory that these so-called "borrowings" are now a punishable offence by virtue of Section 28 of the Road Traffic Act. The Commissioner comments somewhat naïvely on the ease with which burglars and other criminals can facilitate their operations by simply appropriating a car left standing in the street. "Greater use," he says, "should be made of garages." But is a doctor expected to leave his car in a garage every time he visits a patient? If garaging is impracticable, adds the report, drivers leaving their cars unattended should take precautions to prevent them being driven away; "professional criminals dislike work and trouble, and it is almost unknown for a car to be stolen from the street when reasonable precautions have been taken." But the Commissioner is obliged to remind us that "it may be necessary in emergency for the car to be moved by hand in the owner's absence." Indeed, in the London traffic area car-owners have been prosecuted for locking their cars; they intended to frustrate the criminal but they broke statutory regulations. The original London Traffic (Parking Places) Regulations of 1925 merely said that a driver must move a parked car if required by a constable, and that "on the occasion of any public procession or for other good and sufficient reasons or in case of emergency" a constable might move a vehicle whether or not the driver was present. Fresh regulations in 1928 directed that, if a driver left a car unattended at a parking-place, he must so leave it that it may be "moved from one position to another by manual power"; it might be so moved by a police constable in uniform "or other person authorised by such constable" for any reasonable cause in the absence of the driver. These provisions remain unaltered in the superseding regulations of 1929 now in force. It should be noticed that, in the driver's absence, the car is not to be moved otherwise than by hand; anything which makes it difficult for an unauthorised person to start the engine is therefore a legitimate precaution. It should also be noted that these regulations apply only to cars parked at the official parking-places in London scheduled to the 1929 regulations (as from time to time varied). There seems to be no law that a car left temporarily outside a patient's house must be so left that it can be moved even by manual power, though emergencies can be imagined in which such movement might be in the interests of the car-owner.

The use of the mobile squad and of wireless communication with patrols may make things harder for the car-thief. We must wait for next year's figures to see what improvement may be due to such measures. These criminal statistics for London show a serious position. Whether helped by stolen cars or not, burglaries rose from 262 in 1929 to 352 in 1930, and the breaking and entering of buildings other than houses rose from 1539 to 2191.

CORRESPONDENCE

THE CHEMOPROPHYLAXIS OF MALARIA.

To the Editor of THE LANCET.

SIR,—The gratitude of workers in tropical medicine all the world over is due to Colonel S. P. James and his co-workers, Dr. W. D. Nicol and Mr. P. G. Shute, for their convincing demonstration of the value of plasmoquine in therapeutic doses as a prophylactic against malaria infection. (THE LANCET, August 15th, p. 341). That plasmoquine* has a selective action on the sporozoites of malaria is an entirely new scientific fact and one of far-reaching importance. As one who has been actively engaged in endeavouring to assess the exact value of plasmoquine treatment in malaria subsequent to its introduction to therapeutics in 1926, this paper comes as a great encouragement.

There can be no doubt now that plasmoquine has a distinct effect upon the trophozoites of malaria in the blood, but even here, as far as my own observations go and as I have emphasised in my publications on the subject, the drug acts in a different manner to quinine. For instance, it appears to be more efficacious in extirpating the trophozoites of the benign tertian parasite than those of the quartan or subtertian. In fact in subtertian malaria the drug in full therapeutic doses of 0·06 to 0·08 g. daily appears to be unsatisfactory so that clinical and parasitic relapses have occurred in my experience whilst the patient is under treatment, as I reported in my original paper.[1] But the most remarkable effect of plasmoquine is its selective action upon the gametocytes of the malaria parasite upon which quinine (when given uncombined with plasmoquine) appears to act very slowly and with uncertainty. The crescent form, or gametocyte, of the subtertian parasite may be taken as an index of the particularly selective action of the drug which is at present unexplained. Crescents are known to persist for a long time, even for weeks, in the peripheral blood of patients when on full doses of quinine, as I reported in my second paper[2] they have been observed apparently unchanged after the ingestion of grs. 840 (56 g.) of quinine.

The peculiar action of plasmoquine on crescents was first noted by P. Mühlens[3] and later by myself it was figured in the paper just quoted. These observations have been strikingly confirmed by W. Mollow[4] who has given a coloured plate of the curious appearance assumed by these defunct gametocytes. It was thought quite naturally at that time that, in the effective destruction of gametocytes and the sterilisation of the blood resulting therefrom as a means of infecting anophelines, the chief value of plasmoquine chemoprophylaxis (to use the new term) lay.

The combination of plasmoquine with quinine sulphate as first advocated by W. Schulemann and G. Memmi[5] was a distinctive advance, especially in the treatment of subtertian malaria, for the combination with quinine enhanced the value of plasmoquine in the treatment of malaria and apparently counteracted the well-known toxic action of plasmoquine when given uncombined. I have strongly advocated the use of this combined treatment in the routine treatment of malaria in a third paper.[6] This view was then considered too optimistic, but has since received ample confirmation. It is probably true that results obtainable by "plasmoquine compound" treatment in a cool climate are not comparable with those recorded in the tropics, where the climatic and dietetic factors are a detriment to its vis medicatrix and the ultimate recovery of the patient; moreover, it is probably true too, that the initial doses of plasmoquine advocated, 0·08–0·1 g. daily, were far too large. I am now obtaining equally satisfactory results with much smaller doses, such as 0·04 g. plasmoquine daily combined with 0·5 g. quinine sulphate (grs. 7½). Some of the most gratifying results I have had have been in the treatment of malaria in pregnancy, especially in women infected with subtertian malaria where the danger to mother and fœtus is well known. The drug appears to be remarkably well tolerated, and in my experience, now of several cases, leads to the termination of a normal pregnancy and labour without relapses. I have had also satisfactory results in pregnancy with quartan and benign tertian infections and I hope soon to publish these results in extenso.

For the last three years I have advocated the use of plasmoquine compound as a prophylactic to patients returning to the tropics to malaria-infested stations, especially in Central and West Africa, and reports I have had recently from patients who have returned after a tour of service have been most satisfactory. Naturally, I have not had the opportunity of testing my observations upon a large and scientifically conducted scale. My advice has been to take one tablet of plasmoquine compound (plasmoquine 0·01 g.

---

* There has been some confusion about the name and composition of this drug. We are assured by Bayer Products, Ltd., the London agent of its makers, that Plasmoquine, as now issued, is identical with the preparation in the first instance issued under the name of Beprochin. There has been no alteration in its composition. Plasmochin is simply the continental spelling of Plasmoquine. The makers state that Plasmoquine is N-diethylamino-isopentyl-8-amino-6-methoxy-quinoline, obtained synthetically. It is not derived from quinine.—ED. L.

plus quinine sulphate 0·125 g.) last thing at night on going to bed during the malaria season. It is specially important to observe that the drug should never be taken on an empty stomach.

Obviously these valuable observations of Colonel James are going to impart a new stimulus to this aspect of the subject and will probably result in the elaboration of even more satisfactory compounds of plasmoquine and in setting the true and scientific prophylaxis of malaria on a proper and practical basis.

I am, Sir, yours faithfully,

PHILIP MANSON-BAHR.

Weymouth-street, W.1, August 14th, 1931.

IMPRISONMENT FOR MENTAL DISORDER.

To the Editor of THE LANCET

SIR,—I am glad that Prof. Millais Culpin has drawn public attention to the unfortunate man who was sentenced at Hove Police-court to fourteen days' imprisonment for an offence committed when he was alleged to be suffering from loss of memory. On the day following the conviction I telephoned to the Home Office and urged that the case should be investigated. A member of the secretarial staff listened courteously to my plea and promised to look into the matter.

I cannot agree with Prof. Culpin, however, that no blame attaches to the police or the bench. Surely it is not asking too much of the magistrates to expect them to recognise that a man who genuinely fails to know his name and family is in an abnormal mental state, and that the genuineness of his amnesia and its bearing upon his criminal responsibility are matters which should be the subject of medical evidence.

I am, Sir, yours faithfully,

W. RUSSELL BRAIN.

Harley-street, W., August 17th, 1931.

THE LATE LIEUT.-COLONEL LORD.

To the Editor of THE LANCET.

SIR,—I desire the favour of a few lines in which to express the admiration I had, shared with many other members of the Royal Medico-Psychological Association, for the late Lieut.-Colonel Lord. I can speak of him as a friend and colleague in the Medico-Psychological Association and in the Council of Mental Hygiene.

An outstanding feature of his character that could not be overlooked was Colonel Lord's unbounded interest and enthusiasm in the work and welfare of the Association, which has been the means of placing our nurses and mental hospitals in the van of the civilised world. No time or trouble spent on behalf of the Association was grudged by him. A phrase of this kind is often used in complimentary addresses and appreciations, but in Colonel Lord's case it has a special meaning. He held an important post under the London County Council, and this involved a full day's work. Every evening, however, after his official duties for the day were over, he began a second day's work for the Association, and worked on till all the hours of the morning of the next day. The amount of work, mainly of a literary and organising kind, that he overtook during these undisturbed hours in the evening and the night-time, was colossal.

His official post in the Association for many years was that of editor of the *Journal of Mental Science*, itself affording enough scope for the energies of any ordinary man. He discharged the duties of this post—both from the business and scientific points of view—most efficiently, and enhanced the reputation of the journal. Some six years ago he was elected President of the Association and since then he has played an important, if not a leading, part in organising its schemes and enterprises. Nothing that was done by the Association was outwith his interest and activities. The preparation of evidence for the Royal Commission, the presentation of the views of the Association on the new Mental Treatment Act, the elaboration of a new constitution and laws for the Association, now designated Royal; these and similar operations were all influenced by his guidance. The training of mental nurses, their examinations, and their registration by the Association was one of his chief occupations, in view of the fact that their interests had been sacrificed by the General Nursing Council in favour of those of hospital nurses. A permanent memorial of his energy was the creation of the Research Committees of the Association, whereby excellent scientific work has been encouraged with success in our mental hospitals. Lastly, he was secretary and an active member of the Council of Mental Hygiene, and at the International Congress held at Washington last year, he did most useful work for Great Britain.

Colonel Lord did the work of two men, and that under very unfavourable physical conditions. His health during all these years was critical, and when he should have rested, he worked the harder. Being anxious on one occasion on account of his exhausted condition, I spoke to his niece, who then looked after his welfare, to order him to stop work. She answered sadly: "There is no living person who can get him to stop work." If ever a man died in harness, he did. Possibly he found distraction from his anxious physical condition in hard work. At all events, for years he was the most notable example known to me of a brave man struggling against adversity, refusing all compassion, and refusing to acknowledge defeat. His work over, he now rests.

I am, Sir, yours faithfully,

GEORGE M. ROBERTSON.

Edinburgh, August 16th, 1931.

EXCESSIVE SPONTANEOUS INFLATION OF A LUNG CAVITY.

To the Editor of THE LANCET.

SIR,—I read with interest Dr. Blyth Brooke's excellent account of a case diagnosed as excessive spontaneous inflation of a lung cavity (THE LANCET, August 1st, p. 240). One may note that this condition has been observed with manometric control by Dr. Vere Pearson[1] who regards it as a factor in the normal pathogenesis of pulmonary cavities. Dr. W. Mitchell[2] has also concluded that the cavities previously known as pleural rings, which he calls air cysts, are produced possibly by a check-valve action in the ulcerated wall of a bronchus or bronchiole. Such a cavity has been investigated by Dr. Andrew Morland, who informed the Tuberculosis Association last June that he had found a positive pressure in it.

Dr. Blyth Brooke remarks that the diagnosis in his case was between inflated cavity and spontaneous pneumothorax, and suggests that dullness and cavernous breathing posteriorly tend to exclude pneumothorax. However, in such a case as he describes, one would expect adhesions posteriorly to prevent a complete spontaneous pneumothorax, and these would also tend to anchor the mediastinum. Consequently, I should suppose that, judging from his account, Dr. Blyth Brooke inserted his needle either into a compressed cavity or, more probably, through lung into an anterior pneumothorax.

---

[1] Brit. Med. Jour., 1930, i., 380.
[2] Brit. Jour. Radiol., 1930, iii., 446.

One would be disposed to criticise Dr. Blyth Brooke, first, in his choice of the posterior route through lung into the cavity, for there would have been no risk in using an initial needle anteriorly; secondly, in his advocacy of the introduction of pneumothorax needles through lung into dilated cavities for the relief of pain. Such a method would normally be a temporary expedient, for the check-valve mechanism would remain, and also it would occasionally cause unpleasant hæmoptysis.

Dr. Blyth Brooke suggests that "in view of the extent of toxæmia, it was considered that neither an artificial pneumothorax nor a phrenic evulsion would offer her any material assistance." Does he then regard it as *a general principle* that a patient with a unilateral lesion, who is in a very toxic state, is unsuitable for pneumothorax? Surely very careful collapse therapy is exactly what is indicated.

I am, Sir, *yours faithfully*,
H. W. ALLEN.

Bryanston-street, W., August 11th, 1931.

OSTEO-ARTHRITIS.

To the Editor of THE LANCET.

SIR,—In Dr. Philip Figdor's paper on p. 382 of your last issue, he makes the statement that this disease "attacks people who have reached the age of double dentures." I think one may infer from this that Dr. Figdor considers that such people cannot have any oral sepsis. With this point of view I cannot agree, for septic foci in completely edentulous alveolar margins are by no means uncommon, and are as much (if not more) a source of septic infection as abscessed teeth. I called attention to this in a short note in your issue of May 17th, 1930. Dr. Figdor goes on to say that "in those who have teeth, extraction of the remaining teeth seems to make very little difference." Unless these teeth were infected, I do not suppose that it would make any difference. I cannot think that trauma alone is sufficient to account for all the changes found in osteo-arthritis. Would it not be more reasonable to suppose that the trauma prepared a way for microbic action?

I am, Sir, yours faithfully,
J. D. KIDD, M.B.

Queen Anne-street, W., August 14th, 1931.

ANÆSTHESIA IN LABOUR.

To the Editor of THE LANCET.

SIR,—With reference to the communication by Dr. Jane King and Dr. Joyce Morgan on page 346 of your last issue, I have found that satisfactory results can be obtained in private practice without the use of an expensive apparatus. All that is necessary to carry is a 100-gallon cylinder of nitrous oxide. For a small cost a reducing valve can be provided for the cylinder, automatic filling valves for the bag, and a self-administering stop-cock between the bag and the facepiece. Administration can be started towards the end of the first stage. When a uterine contraction begins four deep breaths are taken from the bag, the breath being held after the last to prolong the effect of the gas. The facepiece is then laid aside until the next contraction begins. By this method analgesia is produced. Cyanosis is slight and passes with the next breath of air. An *oxygen cylinder is not required*.

Labour is not prolonged. Full anæsthesia for the birth of the head is *procured with chloroform*. In normal cases the help of an anæsthetist is not essential, the final anæsthesia being entrusted to the nurse. In abnormal cases I have the assistance of an anæsthetist. I am, Sir, yours faithfully,

JAMES RIDDELL, M.D., F.R.C.S. Edin., M.C.O.G.

Plymouth, August 16th, 1931.

LORD KNUTSFORD REMEMBRANCE FUND.

To the Editor of THE LANCET.

SIR,—A letter has been received at the London Hospital enclosing a donation of £1000 and urging that a fund should be started in remembrance of Lord Knutsford. This is but one instance of a very general desire. Many other gifts for the same purpose have already been received, as have a number of letters asking for an opportunity to contribute. We know, too, that collections by groups of workers are being made spontaneously. The committee have therefore decided to open such a fund. There were, at the moment of his death, certain very necessary additions and improvements on which Lord Knutsford had set his heart and to which he had contributed generously, but which he did not live to see completed. It is proposed to devote gifts sent in remembrance to the completion of these objectives, which include a new massage and electrical department, new stores, additional maternity beds and maintenance, and a hostel for students. Will all who wish to honour the name and work of a great man send their contributions to me at the London Hospital, E.1?

I am, Sir, yours faithfully,
EDWARD J. MANN,
August 17th, 1931. Treasurer.

BENDIEN'S WORK ON CANCER.

To the Editor of THE LANCET.

SIR,—During a visit to Zeist, Dr. Bendien has given me ample opportunity of discussing his discovery with him, of seeing him perform his tests, and of talking to and examining his patients. He does not claim to have discovered a cure for cancer, but he believes, and he is most emphatic on this point, that his method of *diagnosis* of cancer in the early and later stages are infallible. He believes carcinoma to be a local disease which can develop only if a specific alteration or, as he puts it, "specific stabilisation" of the serum is present. This abnormality of the serum he can detect by his diagnostic methods. The treatment therefore consists in restoring the *blood* to its normal condition, thus producing a *medium* unsuitable for the growth of cancer. He advises operation in operable cases; his treatment *after* operation, as shown by his serological tests prevents recurrences.

The diagnostic test consists of two parts—namely, flocculation of the serum, and spectro-photometric examination of the precipitate. The first part, the *flocculation*, which is described in your issue of May 16th, p. 1097, Dr. Bendien regards rather as a preliminary, although in experienced hands it may be *sufficient* for a diagnosis of cancer. He tells me that *in* the series of 20 test-tubes containing standard mixtures of acetic acid and sodium vanadate (1) normal human blood-serum always flocculates, if not heated, at No. 6; (2) a serum which flocculates below No. 6 indicates a pathological condition such as carcinoma or tuberculosis; and (3) the lower the number at which flocculation takes place the more concentrated is the "toxic agent" of the serum. Cases flocculating below No. 4 are of particularly bad omen; these are the cases which, according to Dr. Bendien, are inoperable, not in a technical sense, but because dissemination has already taken place, as shown by the great quantity of "toxic" material present in the serum.

The spectro-photometric test, employed for accuracy of diagnosis and as a confirmation of flocculation, is a highly technical process involving mathematical calculation. The precipitate obtained with the acetic vanadate mixture is heated to 56° C. to dissolve what Dr. Bendien calls "normal-labilin" (a protein present in all sera); it is filtered off, weighed, and suspended in $NaHCO_3$ (1 : 50). Suspensions, 20 in all, of various strengths are now submitted to spectro-photometric examination, and 20 photographs of the ultra-violet part of the spectrum are taken. The absorption lines are plotted on a chart and a curve so obtained which is typical of cancer, indicating the presence of a thermostable protein peculiar to it.

Dr. Bendien kindly gave me a full account of the methods and principles of his treatment, but it is impossible for me to go into details here. He wishes me to state that all cases so far treated were inoperable ones, generally with metastases; most of these cases had been submitted to radium, X rays, &c., without success before they came under his care. But in every case he was able with his treatment to obtain an improvement: he does not wish to make any other claim.

I am, Sir, yours faithfully,

A. A. MILLER, M.D., M.R.C.S.

Harley-street, W., August 17th, 1931.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. F. C. Crean to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lts. B. W. C. Archer and H. Winstanley to be Surg. Lt.-Comdrs.

Surg. Sub-Lt. P. B. Moroney and Proby. Surg. Lt. W. R. Johnston to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

Lt. W. A. R. Ross to be Capt. and remain secd.

The undermentioned Lts. (on prob.) are confirmed in their rank: D. A. Langhorne, C. A. de Candole, and W. B. Williams.

ARMY DENTAL CORPS.

The undermentioned Lts. (on prob.) are confirmed in their rank: S. G. Watson and G. T. Drummond.

ARMY RESERVE OF OFFICERS.

Col. A. Chopping, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Col. J. G. Martin, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

Capt. G. W. Wigg from 72nd (Northumbrian) Fd. Bde., R.A., and Capt. K. J. T. Wilson (late R.A.M.C. Spec. Res.), to be Capts.

ROYAL AIR FORCE.

The undermentioned are granted permanent commissions in the ranks stated: Flight Lt. J. H. Cullinan and Flying Officers C. G. Harold and A. Sheehan.

ROYAL AIR FORCE RESERVE.

Flying Officer C. J. MacQuillan is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICE.

Lts. to be Capts.: L. F. Burns, L. Dass, P. C. Dutta, and E. A. O'Connor.

Lt. (T.C.) A. M. H. Shirazi to be Capt. (T.C.).

The undermentioned appts. are made: to be Lts. (on prob.): E. H. Lossing, G. W. Miller, D. G. McCaully, and H. J. R. Thorne.

Lt.-Col. C. J. Stocker retires.

COLONIAL APPOINTMENTS.

The following appointments have been made by the Secretary of State for the Colonies: Dr. R. H. Davidson, M.O., and Dr. T. A. P. Wynter, Government M.O., Jamaica; and Dr. C. A. Stanley, M.O., Malay States; Dr. B. N. V. Bailey, Asst. Government M.O.H., British Guiana, has been promoted Government M.O.H.; Dr. S. G. Harrison, M.O., Gambia, has been transferred to the Gold Coast; and Dr. J. T. Smalley, M.O., Hong-Kong, has been promoted senior M.O.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 8TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 25 (last week 26); scarlet fever, 1250; diphtheria, 759; enteric fever, 62; pneumonia, 472; puerperal fever, 41; puerperal pyrexia, 97; cerebro-spinal fever, 25; acute poliomyelitis, 8; encephalitis lethargica, 11; dysentery, 6; ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 11th–12th was as follows: Small-pox, 46 under treatment, 2 under observation (last week 54 and 2 respectively); scarlet fever, 1159; diphtheria, 1455; enteric fever, 14; measles, 145; whooping-cough, 364; puerperal fever, 42 (plus 8 babies); encephalitis lethargica, 211; poliomyelitis, 3; "other diseases," 135. At St. Margaret's Hospital there were 11 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 12 (1) from measles, 1 (0) from scarlet fever, 15 (6) from whooping-cough, 25 (4) from diphtheria, 33 (7) from diarrhœa and enteritis under two years, and 16 (1) from influenza. The figures in parentheses are those for London itself.

Two deaths from measles were reported from Barnsley, not more than 1 from any other large town. Liverpool reported 5 deaths from whooping-cough and 4 from diphtheria. Diarrhœa was credited with 6 deaths at Birmingham, 3 at Manchester, and 2 at West Hartlepool.

The number of stillbirths notified during the week was 266 (corresponding to a rate of 46 per 1000 births) including 58 in London.

MIDDLESEX POOR-LAW HOSPITALS.—Each of these institutions has had the word "County" added to its name, with the exception of Park Royal Hospital, which will henceforth be called "The Central Middlesex County Hospital." The domestic accommodation at the West Middlesex County Hospital is to be improved at a cost of nearly £13,000.

NATIONAL BIRTH CONTROL ASSOCIATION.—The National Birth Control Council and the Birth Control Investigation Committee have amalgamated under the title of the National Birth Control Association (with which is incorporated the Birth Control Investigation Committee). Sir Thomas Horder has accepted the presidency of the Association, and Sir Humphry Rolleston, who remains chairman of the Birth Control Investigation Committee, will be vice-chairman. The committee has been for over four years investigating the general problem of birth control, as well as the merits and demerits of different methods, while the Council, which was founded last year, has been engaged mainly on work with local authorities in regard to the Ministry of Health's memorandum on birth control. It is stated that so far 35 local authorities have authorised the giving of advice on contraceptive methods. The office is at 26, Eccleston-street, London, S.W. 1.

OBITUARY

WALTER ERNEST DIXON, O.B.E., M.D., F.R.C.P.Lond., F.R.S.

Dr. W. E. Dixon died last Sunday at his home in Cambridge, and the loss will be widely felt. He long played a notable part in the work of the Cambridge medical school, and as expert adviser his exceptional knowledge and experience were freely available in the service of medicine, both national and international.

DR. W. E. DIXON.

(Photograph by J. Palmer Clarke.

The youngest son of Mr. Robert Bland Dixon, of Darlington, Walter Ernest Dixon was educated at Darlington, Dulwich, and St. Thomas's Hospital. He graduated as B.Sc. Lond. in 1891, and as M.B. five years later. After house appointments at St. Thomas's he held posts in the physiological department, and soon began to turn his mind more and more to the action of drugs. At this time pharmacology was receiving little attention or encouragement in this country, but he was granted a Salters Research Fellowship, and began to publish experiments. In due course he became professor of materia medica and pharmacology at King's *College*, but only temporarily, for he was more attracted by the opportunities for investigation offered by Cambridge. He had taken the D.P.H. there in 1898, and in 1902 he was appointed assistant to the Downing professor of medicine, receiving the honorary degree of M.A. In 1909 he became lecturer, and in 1919 reader in pharmacology, and as teacher, writer, and research worker he came to occupy a distinguished place among the pharmacologists of the world.

As a teacher he exerted a profound influence over generations of students, especially in the way of inculcating the physiological basis of therapeutics. At the outset of his Cambridge courses he captured the attention of undergraduates, and he retained it to the very end. Pharmacology became the most fascinating of studies, because Dixon, with his cynical humour, was one of the best of lecturers. So stimulating an instructor was much in demand outside his own university, while at the same time nearly every medical school in the country invited him to become an examiner. In this capacity he was often regarded with alarm, and his methods did nothing to encourage the candidates' self-conceit, but he was always fair, and even lenient in his final decision.

Dixon was a prolific writer, and contributed to Hale White's "Text-book of Materia Medica," Heffter's "Pharmacology," Allbutt's "System of Medicine," and the British Pharmaceutical Codex, to mention only a few. His "Manual of Pharmacology," which has passed through many editions, has been the avenue through which medical practitioners all over the country have approached their examination in this subject. He succeeded Cushny as the senior editor of the *Journal of Pharmacology*, and was on the editorial committee of several other scientific journals. He also served on many important commissions and committees, including that which the League of Nations set up to consider drug addiction. In this capacity he was valued not only for his authoritative knowledge but also for his faculty of singling out the essential points of a problem.

As an investigator, he made many contributions to physiology and pharmacology which covered a wide field. Among them may be mentioned his researches on apocodeine, tyramine, histamine, and digitalis, on general problems of pharmacology, especially tolerance and site of action of drugs; but of chief importance was his pioneer work on the physiology and pharmacology of the bronchial muscle and on the cerebro-spinal fluid. In all his researches he brought to bear a fearless and original mind, never afraid to question tenets apparently established, and he devised many improvements in pharmacological technique. He had, moreover, the faculty of gathering young men around him and interesting them in research work. He was full of ideas, often heterodox, and many of his old pupils, who now occupy important teaching positions, would willingly acknowledge his help, guidance, and inspiration.

Dr. O. Inchley, lecturer on pharmacology at King's College, London, writes: "On the title page of his 'Manual of Pharmacology' appears a quotation from Renan, 'Dire n'est rien; faire est tout,' which, to me, gives the keynote of Dixon's life-work. Not long ago the assertion of physicians as to the beneficial action of this or that drug in this or that disease was taken on faith. To-day the actions of drugs are determined physiologically by experimental methods, and in the birth of this modern science of pharmacology Dixon took an outstanding position. His manual contains liberal illustrations of kymograph tracings, each in itself an accurate experimental record and supplying the student with facts rather than opinions. The simple experiments suitable for class work set out in his 'Practical Pharmacology' convince the student, *by his own observation*, of the action of the drug on the animal. Dixon's lectures were never stodgy. His personality insured that whatever he touched was raised from the commonplace. We, who knew him intimately, knew that whenever he was with us we should never be bored. Dixon at the dinner table, Dixon on a walking tour, or Dixon on a rock scramble in Sark was the leader, life, and soul of the party. His wit was sprightly and never cruel. He excelled as a raconteur, and some of his most amusing tales were against himself."

"The subject of pharmacology," writes Prof. J. A. Gunn, "has suffered grievous losses in the last few years—Cushny, Magnus, Loevenhart, Trendelenburg, and now Dixon, all men in the front rank, and all, one hoped, with fruitful years of work still before them. For one who has enjoyed an uninterrupted friendship with Dixon for over a quarter of a century, and who has experienced nothing but kindness and encouragement from him, it is difficult at present to write any coherent appreciation of his work. He had come to be accepted, since Cushny's death, as the leader of academic pharmacology in this country, and his loss, when we have so few pharmacologists, and indeed few medical men with his wide training and outlook, is in the meantime irreparable. No one who knew him will forget his arresting personality. A wide and unusual knowledge of men and things, a gift for telling stories, an infectious and almost boyish enthusiasm, made him a delightful and resourceful companion."

Dr. Dixon became an F.R.S. in 1911. In 1930 he was elected F.R.C.P., and he was recently appointed to deliver the Croonian lectures. At one time and another he was president of the section of pharmacology of the British Medical Association, president of the section of therapeutics of the Royal Society of Medicine, and president of the section of physiology of the British Association. Last year he received the honorary degree of LL.D. of Manitoba. During the war, with a nominal appointment in the Royal in the Navy, he played an obscure but important part intelligence department, especially in connexion with secret service in Spain. For this he was created O.B.E.

At the time of his death Dr. Dixon was 60 years of age. He married in 1907 the only daughter of the late Mr. Francis Glen-Allan, of Dulwich, and their house at Whittlesford was known for its generous hospitality.

MARTIN WILLIAM FLACK, C.B.E., M.B. Oxf.,

DIRECTOR, MEDICAL RESEARCH DEPARTMENT, R.A.F.

WE regret to record the death on Sunday last of Group-Captain Martin Flack, the distinguished physiologist, who became the first director of the Medical Research Department of the Royal Air Force.

Martin William Flack, the son of Mr. E. C. Flack, of Borden, Kent, was born in 1882, and received his early education at the Great Yarmouth and Maidstone Grammar Schools. He proceeded to Keble College, Oxford, with a science exhibition, and took up the study of medicine, coming under the influence of such potent teachers as the late Prof. Gotch, Prof. Arthur Thomson, and Prof. J. S. Haldane. He graduated in Arts at Oxford in 1905, and completed his medical education at the London Hospital, where he held a scholarship. While at the London Hospital he was associated with Sir Arthur Keith in an investigation into the nerve-muscle structure of the heart,[1] and he also carried out, in collaboration with Sir Leonard Hill, a preliminary inquiry into the physiology of respiration. He graduated in medicine at Oxford in 1909, and was elected to a Radcliffe Travelling Fellowship. In accordance with the terms of the Fellowship he spent a year on the continent, mainly continuing his study of respiratory physiology, and on his return to England became assistant to Sir Leonard Hill, who was holding the chair of physiology in London University at the London Hospital Medical College. Flack was appointed lecturer in physiology and chemical pathology at the college, and later was associated with Hill's work at the Medical Research Council in the department of applied physiology. It was with these credentials that he came to the notice of the Air Ministry, who in the early days of the war were instituting a department of medical research specially directed to the elucidation of the problems of aviation as they affected the personnel of the Service.

GROUP-CAPTAIN FLACK.

[Photograph by Russell and Sons.

From the beginning Flack proved an unqualified success in a new and difficult appointment. He was saturated with the kind of knowledge whose application was most desirable, and had that knowledge wonderfully well sorted, for he had been a successful teacher of physiology, and was actually in the middle of writing a text-book with Sir Leonard Hill on the subject when the war broke out. He had assisted in valuable demonstrations of practical pathology, much of which bore directly upon the very questions which the new department would have to answer. His personal researches into important phenomena of the physiology of heart and respiration were exactly of the sort to stand him in good stead in devising tests which would assist in the recruiting of the candidates for the service. The report for 1920 of the Royal Air Force may be called in evidence for these statements. It contained a section describing a Medical Board for aviation candidates which showed how thoroughly Flack and his willing collaborators had faced the devising of a course of training and a method of inspection and examination which should result in securing the right men for a dangerous service—in essence the procedure was directed to removing, as far as possible, the element of danger. The result of this work was to make it necessary for the candidate to pass a medical examination to prove physical fitness, to provide evidence of good personal history, and to emerge successfully from a physiological assessment, based upon tests of the cardiac, respiratory, and nervous systems. An anthropometric index of physical fitness was devised, and standards were laid down which, though not unduly high, would lead to the inevitable rejection of recruits whose acceptance would be cruelty to themselves and dangerous to their colleagues. The first Director of Medical Research in the Royal Air Force Medical Service died while still holding the appointment which he was so adapted to fill and develop. He had borne a long illness in the Air Force Hospital at Halton before the end came in his fiftieth year. The Air Force owes him an inextinguishable debt.

Group-Captain Flack married Cecile, daughter of Mr. J. C. Cooper, and his widow survives him, with two sons and two daughters.

SHEPHERD McCORMICK BOYD, F.R.C.S. Irel.

THE death of Dr. Shepherd Boyd, of Harrogate, on August 8th, will be regretted by many whom he befriended and many who appreciated his unusual charm. Seventy-five years of age, he was the son of Dr. John William Boyd, once the oldest doctor in Ireland, who died at the bedside of a patient after 57 years of practice from one house. After attending Kilkenny College and Devon County School the son went to Trinity College, and distinguished himself as one of the best oarsmen Dublin has produced. Twice he reached the final of the Diamond Sculls at Henley, and in other branches of athletics his achievements were sound, if not so brilliant. He qualified in 1880, became F.R.C.S. Irel. three years later, and saw many different sides of life as practitioner in his home town of New Ross, medical officer of Cork-street Fever Hospital during a small-pox epidemic, ship's surgeon on the Nile, resident at Manchester Maternity Hospital and Chelsea Dispensary, and surgeon to a mining company in Yorkshire and an ironworks in Wales. He practised in Manchester for some years, moved to Bexhill, and finally settled at Harrogate some 27 years ago. But his life as a spa practitioner was yet to be interrupted by the war. From youth onwards an enthusiastic volunteer and territorial, he was well "over age" on the outbreak of war, but nevertheless got to France and remained there until after the Armistice. During an air-raid in Boulogne his hearing was badly damaged, but in spite of this disability he joined an ambulance train in 1918 and survived an almost direct hit by a bomb at Étaples. Deafness, largely, if not entirely due to this war service, was a serious trial during the latter part of his life, and he had to contend with other illness. "But," writes a colleague, "he presented a picture of triumphant personality dominating by its own inherent strength the lesser tragedies that might well have daunted a lesser man. . . . He was marked out by an extraordinary kindness of nature, and no trouble was too great for him to take to help anyone who appealed for his sympathy or his aid. Coupled with this kindly nature was a sparkling and irrepressible gaiety of spirits." He was especially encouraging and helpful in his treatment of recently qualified members of the profession.

[1] THE LANCET, 1906, ii., 359.

Dr. Shepherd Boyd was long associated with the Irish Medical Schools and Graduates Association, and the Association of British Postal Medical Officers, and was at one time president of the Harrogate Medical Society. His wife survives him, and a son.

Dr. WILLIAM BURNS, who died on August 4th whilst attending a patient in the dispensary at Glengall-street, Belfast, was a student of Queen's College, qualifying at Glasgow in 1901. He then volunteered for special plague duty in India, returning after two years to take up general practice in Belfast. In 1910 he took the D.P.H. Belf., with a view to appointment as part-time medical officer of health for the urban district. Dr. Burns is described by a colleague as one whose joy in life endeared him to his colleagues, while his devotion and skill produced a host of patients who regarded him not only as their medical adviser, but as a friend to whom they could bring all their difficulties. Thousands of persons lined the route when his body was laid to rest amid the beautiful surroundings of Knockbreda. Dr. Burns was in his sixty-first year.

MEDICAL PRACTICE IN CHINA.—It is announced that foreign medical practitioners wishing to practise in China should forward their examination diploma and any other documents attesting their qualifications to the nearest consul of their nationality for his inspection, with a request that he issue a certificate. When this certificate has been obtained, it should be forwarded, together with a statement of the applicant's record, two 2-in. half-figure photographs, a registration fee of five dollars, and a stamp-tax fee of two dollars, to the appropriate local government department (i.e., the health bureau, or, if the district has no health bureau, then the Public Safety Bureau or the district government) for transmission to the health section of the Ministry of the Interior.

MEDICAL NEWS

THE annual general meeting of the Medical Sickness Annuity and Life Assurance Society Ltd., will be held at the First Avenue Hotel, High Holborn, London, W.C., on Wednesday, Oct. 7th, at 4.30 P.M.

London Hospital Saturday Fund.

The annual street collections for this fund will be held *on Sept. 26th.*

University of Manchester.

The Prof. Tom Jones Memorial Fellowship in Surgery has been awarded to Dr. A. L. Kenyon.

St. Mary's Hospital Dinner.

The annual dinner of past and present students will be held at the Trocadero Restaurant, London, W., on Friday Oct. 2nd, at 7 for 7.30 P.M. Sir William Willcox will preside.

Royal Sanitary Institute.

Lord Leconfield, *Lord Lieutenant* of Sussex, and chairman of the West Sussex County Council, has consented to act as president of the forty-third congress of the Institute, to be held at Brighton from July 9th to 16th, 1932.

Post-graduate Courses in Berlin.

From Oct. 5th onwards a number of international post-graduate courses will be held in Berlin on general and special subjects. The latter include pædiatrics, urology, medical psychology, intrathoracic surgery, and physical and dietetic treatment. In the spring there will be further courses on radiology, surgery, obstetrics, industrial medicine, and ophthalmology. Particulars may be had from the information bureau of the Kaiserin Friedrich-Haus, Luisenplatz 2, *Berlin*, N.W. 6.

Manchester Radium Institute.

Dr. Ralston Paterson has been appointed director of the Manchester Radium Institute in succession to the late Dr. A. E. Birkett. He will also be director of the national radium centre at Manchester, and will superintend the use of radium lent by the Radium Trust to the Royal Infirmary and the Institute. Dr. Paterson, who is at present working at the Edinburgh Royal Infirmary, has lately spent four years in the United States and Canada, and has made an extensive study of radiological methods there employed.

Congress of Tropical Medicine.

The second International Congress of Tropical Medicine will be held at Amsterdam from Sept. 12th to 17th, 1932, under the presidency of Prof. G. Grijns. The subjects of discussion will be (1) avitaminoses, with special reference to beri-beri; (2) yellow fever and leptospiroses; (3) helminths, with special reference to ancylostoma; and (4) malaria, with special reference to blackwater fever. Those wishing to participate in the Congress are asked to inform the general secretary (Prof. E. P. Snijders, Institute of Tropical Hygiene, Mauritskade, 57, Amsterdam) before *the end of this year.*

Fellowship of Medicine and Post-Graduate Medical Association.

The following are the subjects of special courses to be held in September: diseases of the chest at the Brompton *Hospital, from* Sept. 7th to 12th (all day); psychological medicine, at the Bethlem Royal Hospital, from Sept. 8th to Oct. 3rd (Tuesdays and Saturdays at 11 A.M.); diseases of infants, at the Infants' Hospital, from Sept. 14th to 20th (every afternoon); ophthalmology, at the Central London Ophthalmic Hospital, from Sept. 8th to Oct. 3rd (every afternoon); and medicine, surgery, and the special departments, at the Westminster Hospital, from Sept. 14th to 20th (all day, men only). Syllabuses of these courses may be had from the secretary of the Fellowship at 1, Wimpole-street, London, W.1. A series of free lectures on Prognosis will begin early in October, and also the usual series of free demonstrations in medicine and surgery—one a week in each subject at different hospitals.

and indeed few medical men with his wide training and outlook, is in the meantime irreparable. No one who knew him will forget his arresting personality. A wide and unusual knowledge of men and things, a gift for telling stories, an infectious and almost boyish enthusiasm, made him a delightful and resourceful companion."

Dr. Dixon became an F.R.S. in 1911. In 1930 he was elected F.R.C.P., and he was recently appointed to deliver the Croonian lectures. At one time and another he was president of the section of pharmacology of the British Medical Association, president of the section of therapeutics of the Royal Society of Medicine, and president of the section of physiology of the British Association. Last year he received the honorary degree of LL.D. of Manitoba. During the war, with a nominal appointment in the Royal in the Navy, he played an obscure but important part intelligence department, especially in connexion with secret service in Spain. For this he was created O.B.E.

At the time of his death Dr. Dixon was 60 years of age. He married in 1907 the only daughter of the late Mr. Francis Glen-Allan, of Dulwich, and their house at Whittlesford was known for its generous hospitality.

MARTIN WILLIAM FLACK, C.B.E., M.B. Oxf.,

DIRECTOR, MEDICAL RESEARCH DEPARTMENT, R.A.F.

WE regret to record the death on Sunday last of Group-Captain Martin Flack, the distinguished physiologist, who became the first director of the Medical Research Department of the Royal Air Force.

GROUP-CAPTAIN FLACK.

[Photograph by Russell and Sons.

Martin William Flack, the son of Mr. E. C. Flack, of Borden, Kent, was born in 1882, and received his early education at the Great Yarmouth and Maidstone Grammar Schools. He proceeded to Keble College, Oxford, with a science exhibition, and took up the study of medicine, coming under the influence of such potent teachers as the late Prof. Gotch, Prof. Arthur Thomson, and Prof. J. S. Haldane. He graduated in Arts at Oxford in 1905, and completed his medical education at the London Hospital, where he held a scholarship. While at the London Hospital he was associated with Sir Arthur Keith in an investigation into the nerve-muscle structure of the heart,[1] and he also carried out, in collaboration with Sir Leonard Hill, a preliminary inquiry into the physiology of respiration. He graduated in medicine at Oxford in 1909, and was elected to a Radcliffe Travelling Fellowship. In accordance with the terms of the Fellowship he spent a year on the continent, mainly continuing his study of respiratory physiology, and on his return to England became assistant to Sir Leonard Hill, who was holding the chair of physiology in London University at the London Hospital Medical College. Flack was appointed lecturer in physiology and chemical pathology at the college, and later was associated with Hill's work at the Medical Research Council in the department of applied physiology. It was with these credentials that he came to the notice of the Air Ministry, who in the early days of the war were instituting a department of medical research specially directed to the elucidation of the problems of aviation as they affected the personnel of the Service.

From the beginning Flack proved an unqualified success in a new and difficult appointment. He was saturated with the kind of knowledge whose application was most desirable, and had that knowledge wonderfully well sorted, for he had been a successful teacher of physiology, and was actually in the middle of writing a text-book with Sir Leonard Hill on the subject when the war broke out. He had assisted in valuable demonstrations of practical pathology, much of which bore directly upon the very questions which the new department would have to answer. His personal researches into important phenomena of the physiology of heart and respiration were exactly of the sort to stand him in good stead in devising tests which would assist in the recruiting of the candidates for the service. The report for 1920 of the Royal Air Force may be called in evidence for these statements. It contained a section describing a Medical Board for aviation candidates which showed how thoroughly Flack and his willing collaborators had faced the devising of a course of training and a method of inspection and examination which should result in securing the right men for a dangerous service—in essence the procedure was directed to removing, as far as possible, the element of danger. The result of this work was to make it necessary for the candidate to pass a medical examination to prove physical fitness, to provide evidence of good personal history, and to emerge successfully from a physiological assessment, based upon tests of the cardiac, respiratory, and nervous systems. An anthropometric index of physical fitness was devised, and standards were laid down which, though not unduly high, would lead to the inevitable rejection of recruits whose acceptance would be cruelty to themselves and dangerous to their colleagues. The first Director of Medical Research in the Royal Air Force Medical Service died while still holding the appointment which he was so adapted to fill and develop. He had borne a long illness in the Air Force Hospital at Halton before the end came in his fiftieth year. The Air Force owes him an inextinguishable debt.

Group-Captain Flack married Cecile, daughter of Mr. J. C. Cooper, and his widow survives him, with two sons and two daughters.

SHEPHERD McCORMICK BOYD, F.R.C.S. Irel.

THE death of Dr. Shepherd Boyd, of Harrogate, on August 8th, will be regretted by many whom he befriended and many who appreciated his unusual charm. Seventy-five years of age, he was the son of Dr. John William Boyd, once the oldest doctor in Ireland, who died at the bedside of a patient after 57 years of practice from one house. After attending Kilkenny College and Devon County School the son went to Trinity College, and distinguished himself as one of the best oarsmen Dublin has produced. Twice he reached the final of the Diamond Sculls at Henley, and in other branches of athletics his achievements

NOTES, COMMENTS, AND ABSTRACTS

HOSPITALS AND MOTORING ACCIDENTS.

RECOVERY OF EXPENSES OF TREATMENT.

A MEMORANDUM[1] has been prepared by a barrister for the Central Bureau of Hospital Information explaining in non-technical language the effect of Section 36 (2) of the Road Traffic Act, 1930, in so far as it gives hospitals a claim on insurance companies for the expenses of treatment in hospital of the victims of motor accidents. The memorandum also deals with certain difficulties that have arisen in practice under the Act, and contains the answers to a number of inquiries that have been received.

It must be realised that Section 36 (2) of the Road Traffic Act is intentionally restricted in its effect, and that, large as is the number of victims of motor accidents who are treated in hospitals every year, insurance companies will only have to make payments to hospitals in respect of such treatment in a very small proportion of cases. This proportion is, in fact, estimated to be about 10 per cent.

HOSPITALS ENTITLED TO PAYMENT.

Payment for the expenses of treatment of victims of motor accidents can be claimed by any hospital that is "an institution which provides medical or surgical treatment for in-patients." The question has been raised whether this definition includes a hospital where it is usual only to provide nursing and accommodation, leaving the patients to arrange with their own doctors to attend them. The answer is that, so long as there is any medical staff who would ordinarily deal with emergency cases, the hospital comes within the definition. In the rare case where there is no such staff, the answer will depend on the judicial interpretation of the words "medical or surgical treatment"; in the meantime it is recommended that claims should be put in against insurance companies in all such cases.

CONDITIONS UNDER WHICH CLAIM CAN BE MADE.

The right of a hospital to obtain a payment from an insurance company for the expenses of treatment of the victim of a motor accident depends on the following conditions being fulfilled:—

(*a*) The victim must, as a general rule, be either (i) a person who was not in the car that was responsible for the accident, or (ii) a person who was a paying passenger in the car.

(*b*) The insurance company must have made a payment to the victim or his dependents in respect of his personal injury or death.

(*c*) The victim must have received treatment in the hospital as an in-patient.

(*d*) The hospital must not have made any charge in respect of the victim's treatment.

Even when all these conditions *are* fulfilled, the hospital will not *necessarily* be entitled to a payment from an insurance company. These conditions are merely the sine qua non for any such payment.

VICTIMS IN RESPECT OF WHOM CLAIM CAN BE MADE.

It is only in respect of a very restricted class of victims that the expenses of treatment can be recovered by hospitals from insurance companies. The owner or driver of the car responsible for the accident will never come within the class. The car owner's friends or employees, being driven in the car, will come within this class when the policy has been specially so drawn as to include them, but not otherwise. If it is possible for the hospital secretary to see the policy issued by the insurance company in any particular case, he will be able to satisfy himself as to the exact classes of persons covered by the policy.

"A person not in the car that was responsible for the accident" of course includes any person in any *other* car that is involved in the same accident, as well as a pedestrian, a rider, &c. The question of responsibility for an accident is often most difficult to decide, especially when more than one car is involved in it, but fortunately, hospitals need not concern themselves with this point, as it will be decided for them. As, however, it will always be difficult for a hospital to know whether it has a good claim for the expenses of treatment of each individual patient, it is recommended that notice should be given to insurance companies concerned of every victim of a motor accident that is admitted to the hospital.

CASES IN WHICH HOSPITALS HAVE NO CLAIM.

In the following cases the victim will receive no payment from an insurance company, and consequently the hospital will not be entitled to any payment from the insurance company for the expenses of the victim's treatment.

(*a*) If the driver or owner of the car responsible for the accident is himself killed, or dies before his victim obtains a judgment for damages against him, or before his claim is otherwise settled.

(*b*) If the victim of the accident dies before his claim is decided, and he leaves no dependents who are entitled to claim damages for his death.

(*c*) When the accident has been caused by an uninsured person in a stolen car, or in a car he is not authorised to use.

(*d*) When the accident has been caused by a car owned by a local authority or a police authority, by an invalid carriage—i.e., specially designed for use by a person suffering from a physical disability—or by a tram car or trolley vehicle the use of which is authorised by special Act of Parliament or Order

PAYMENT BY INSURANCE COMPANY TO VICTIM OR DEPENDENTS.

Is it necessary to prove the negligence of the car driver before the hospital can recover a payment from the insurance company? The answer is that *the hospital* is not concerned with any question of negligence, but must merely ascertain whether any payment to the victim or his dependents has in fact been made by the insurance company under its policy; if such a payment has been made, then the insurance company must also make a payment to the hospital in respect of that victim's treatment. In point of fact the insurance company will only make this payment to the victim either (i) if it is agreed, or has been decided in court, that the car owner or driver insured by this company was responsible for the accident, or (ii) if responsibility is not proved or admitted, but the insurance company, in order to avoid legal proceedings, makes a payment to the victim by way of a compromise of his claim —called a "compassionate grant."

As the recovery by hospitals of expenses of treatment from insurance companies depends on the victim having actually received some payment in respect of his injury, it may possibly be worth the while of hospitals to consider whether they could obtain the honorary services of a local solicitor to look into the claims of victims (being patients in hospital) who either neglect, or have not the means, to take the necessary steps for pressing their claims themselves.

EXPENSES OF TREATMENT THAT CAN BE RECOVERED.

The claim of a hospital against an insurance company is limited to £25 for each patient. Subject to this, the hospital can claim, at the rate of the average cost of an occupied bed per day, for the number of days that the victim has been treated as an in-patient. The average cost of an occupied bed per day is arrived at by taking the hospital's total annual expenditure on the maintenance of the hospital and its staff, and on the maintenance and treatment of patients, and dividing this figure by the total of daily counts of in-patients.

---

[1] Copies on application to the Director of the Bureau, 12, Grosvenor Crescent, London, S.W. 1. 3*d*. post free.

Claims for payment can only be made in respect of in-patient treatment. No extra payment can be claimed for an operation or for any special form of treatment. There appears to be an idea that the Act would allow a hospital to pay its medical staff special fees for attending motor-accident patients, and to increase the costs to be recovered from an insurance company by the amount of such fees. It is quite clear that the Act does not allow of this being done. The costs per day to be recovered for a motor-accident patient must be the same as the average cost for *all* the patients in the hospital.

CHARGES MADE BY A HOSPITAL FOR TREATMENT.

The condition that "the hospital must not have made any charge in respect of the victim's treatment" gives rise to several difficulties, and raises the question as to what payments hospitals can receive from victims without losing their claim against insurance companies.

(*a*) *Voluntary payments by victim.*—It seems clear that a purely voluntary payment by a victim to the hospital cannot legally prejudice the hospital's claim for a subsequent payment from the insurance company. Whether it is quite fair to insurance companies that hospitals should receive both payments is another matter, and this question might well be considered when some general agreement between hospitals and insurance companies is being negotiated.

(*b*) *Invitation to pay part of cost of treatment.*—In hospitals where the usual practice is to invite patients to make such payment as they are able towards the expenses of their treatment, the question has been raised whether the acceptance of such a payment from the victim of a motor accident could be considered as "making a charge." Although the matter is not free from doubt, it is thought that such a payment may safely be treated as a voluntary payment; but care should be taken that the payment is expressly made as a "donation."

(*c*) *Practical difficulty of deciding whether to make a charge or not.*—When it is the practice in a hospital to make a definite charge to a patient of what it is thought he can pay, it is now difficult to decide how to proceed in motor accident cases.

The hospital is in a dilemma; if it makes any charge to the victim while he is in hospital, it loses its claim for a payment by the insurance company—and this payment *might* be considerably more than the victim could pay; but if it makes no charge for treatment while the victim is in hospital, and if, after the victim has left, it turns out that the hospital has no claim against the insurance company, then it will probably be too late to recover anything from the victim.

There appears to be no way out of this difficulty at present, and it can only be solved by some general agreement with insurance companies. One suggestion, which appears to be an equitable solution, is that the hospital should obtain what payment it can from the victim while he is in hospital, and deduct the amount of this payment from its claim against the insurance company. Hospitals might perhaps endeavour to come to an agreement with insurance companies on these lines in individual cases, pending the negotiation of a general agreement.

(*d*) *Payments to hospitals under certain contributory schemes.*—If the victim of an accident is treated in hospital, and the hospital claims a payment for such treatment out of the funds of a contributory scheme to which the victim subscribes, the question has been raised whether this claim must be considered as a "charge for treatment," and so preclude the hospital from obtaining a further payment from the insurance company. This again appears to be a subject on which some general agreement with insurance companies should be reached.

METHODS OF EVASION.

Some insurance companies are attempting to evade part of their liability under the Road Traffic Act. In some cases, an insurance company, before settling the victim's claim, has tried to bargain with a hospital as to its claim for expenses of treatment, and to persuade the hospital to accept less than the full amount to which it is entitled. Insurance companies have no right to do this, as the method of calculation of what they must pay to hospitals is clearly stated in the Act. In other cases, an insurance company has agreed to pay a definite sum to the victim under the policy, and has subsequently deducted from this sum the amount of the payment made by the insurance company to the hospital. Strictly speaking, this does not concern hospitals. The matter must be settled between the insurance companies and the victims. In other cases the insurance company announces to the hospital that it is proposing to make an ex gratia grant to the victim, but will only make the grant if the hospital undertakes not to demand any payment from the insurance company for the expenses of the victim's treatment. Such a threat by the insurance company is most improper.

The practical difficulty in all these cases is that if hospitals stand on their legal rights, it will probably result in insurance companies being less generous in the settlement of the claims of victims; and if this becomes apparent, it will obviously have the effect of raising a prejudice against hospitals, as it will be said that the hospitals are receiving payments which ought to have been made to the injured. Probably the only satisfactory method of settling these questions will be by a general agreement with insurance companies.

PROCEDURE IN MAKING CLAIMS.

Whenever the victim of a motor accident is brought to a hospital, information should at once be obtained from the police as to the registration numbers of all cars involved in the accident, the names of their owners, and the insurance companies by whom they are insured against third-party risks. A notice should then be sent to the insurance company—or to each insurance company, if more than one car is involved. As soon as the victim leaves hospital, or, if he has to stay in hospital for a long time, as soon as the expenses of his treatment (calculated at the average daily cost of an occupied bed in that hospital) amount to £25, a formal claim for the expenses of treatment should be sent to the insurance company. The memorandum suggests the phrasing of these notices of claim.

ALCOHOLIC CRAVING.

IN the course of a paper on the Alcohol Habit, read to the Paddington Medical Society on August 11th, Dr. ALEX. BALDIE discussed the nature of the craving for alcohol, which was bound up with that of the craving for all drugs of a habit-forming tendency. Its causes might, he thought, be fairly if briefly summarised as follows:—

ITS CAUSES.

(1) The chemical influence exerted by the drug on metabolism—an influence for good or ill which is liable to become more specific and indispensable as tolerance is established.

(2) The conscious contrast between the cerebral relaxation induced by alcohol and the emotional release consequent on such relaxation, and the mental lassitude experienced when the effect of the drug has passed.

(3) Automatism. Repetitive acts, whether whistling, humming a tune, scratching the head, biting the nails, interminably lighting and puffing a cigarette, or calling for drinks, all equally act as diversions to a mind preoccupied. An act repeated becomes a habit, the habit a vice, and the vice a destiny.

(4) Misinterpretation of natural thirst and fatigue.

To describe the nature of the habit in other words he quoted Trotter ("Instincts of the Herd in Peace and War"): "Almost universally regarded as either, on the one hand, a sin or vice, or, on the other hand, as a disease, there can be little doubt that in fact (the alcohol habit) is essentially a response to a psychological necessity. In the tragic conflict between what he has been taught to desire and what he is allowed to get man has found in alcohol a sinister but effective peacemaker . . . . a way out of the prison house of reality."

This escape from reality—that is, from emotional and intellectual tension—or relaxation, is an easy process normally for a good many people. We all know the fortunate ones who are able at will to relax either into slumber, as for 40 winks in an armchair, or into gaiety and irresponsibility after strenuous mental work. This process, easy and habitual to a favoured few, is impossible without the aid of narcotics to the vast majority of mankind. Hence the desire for such aid, and—too often—for its immoderate use. Hence also the misunderstandings and the differences of opinion as to the necessity for its use, and the irritation engendered by propaganda and legislation directed towards its restriction.

FATIGUE A CONTRIBUTORY FACTOR.

Alcoholics tire easily, as do other debilitated persons. Periodic rest at short intervals tends to prevent the sense of fatigue which is a contributory element in the craving to which they are subject. Even in normal civilised persons the sleep function is sufficiently abused. A continuous period of 16 hours of wakeful activity in the perpendicular attitude, followed by habitual slumber for eight hours in the horizontal, does not appear physiologically the most desirable habit. It has no parallel amongst the mammals at any rate. The tired nervous system of the chronic alcoholic responds quickly to a recuperative régime—such as, for workers, a short diversion and physical relaxation every two or three hours. This need not be for more than about ten minutes. It should be accompanied by the regular drinking of a variable quantity of liquid. Also complete relaxation for about an hour, after the mid-day meal, should be encouraged. It is unfortunate that the conditions of modern life, which provide abundant toilet facilities in public places, and opportunities everywhere for exercise, recreation, and refreshment, should provide none for rest; so that an individual miles away from his home, as many are compelled by reason of their occupation to be, cannot obtain rest and privacy, short of the somewhat expensive and eccentric process of taking a room in a hotel for an hour. Lucky are those exceptional persons who are able, at will, to steal 40 winks in a crowded tube train or on a hard seat in Trafalgar-square. The facilities afforded in this respect until recently by the silent film have been considerably curtailed by the advent of the "talkies."

ITS REDUCTION.

No treatment of chronic alcoholism can be effective which does not include a deliberate attempt to strengthen the will of the patient to discard the drug and to understand and undermine the potency of the craving which is his besetting sin, vice, and disease. This is the part of the treatment which is difficult and complex since it must be approached on special psychotherapeutic lines; but here, as in other directions, the family doctor, by virtue of his intimate knowledge of him, may be able to guide and control his patient's diseased tendency. The craving may not necessarily be simple in its origin—few cravings are—but an understanding of possible causes may suggest a simple and practical method of treatment.

(1) The craving may be due in part to the established and specialised influence on metabolism which we know alcohol possesses. To this extent its replacement by other forms of fuel, such as sugar, may be of use.

(2) The unrelieved overactivity of the higher mental faculties, from the strain of which alcohol has provided an habitual escape, must be avoided and another escape discovered. In other words, outlets for the expression of repressed emotion should be cultivated, in the form of recreations, interests, and pursuits most adapted to the physical and psychological personality with which we have to deal.

(3) The alternations of high and low blood pressure induced by the alcoholic transformation should be borne in mind. Generally depression and despair go with a low blood pressure; energetic and high-spirited optimism with a high. It is in its effects in this direction that exercise and occupation, not fatiguing and preferably of some useful, interesting, and remunerative kind, is indicated.

(4) The not unimportant influence of the repetitive and automatic nature of the drinking ritual requires attention. The mental preliminaries to "another little drink" may be active against the conscious will and knowledge of the patient, who must be alert to understand his unconscious tendencies and to break the repetitive chain. "Substitution" habits may be objectionable, but may help.

(5) Misinterpretation of simple thirst will be avoided if the patient assuages his natural thirst periodically with small doses of aqua pura. Misinterpretation of fatigue will be prevented by periodic rest.

ITS PREVENTION.

The majority of civilised mankind, said Dr. Baldie, uses alcohol moderately and with benefit. But the considerable minority who through idiosyncrasy, foolishness, or excess is unable to consume it safely or beneficially requires something more than exhortations and threats if it is to be influenced. Probably there is scope for yet another "temperance" society, which shall be free from all ulterior motive, and which will help ignorant persons to understand the pros and cons of alcoholic indulgence, and to know how, when, and where to stop. The following suggestions for the rational indulgence in alcoholic liquors might be of help to such a society:—

(1) Drinks should be avoided invariably between meals.

(2) They should not as a rule be used to assuage excessive thirst.

(3) They should be avoided generally during mental or physical exertion.

(4) They should be avoided absolutely under all conditions requiring the exercise of skill, judgment, and technical or mechanical efficiency.

(5) All non-teetotallers should imbibe by the clock small quantities of fresh water, since some part of the alcoholic craving is unconsciously due to natural thirst, and natural thirst is not to be assuaged by anything but pure water.

(6) The wheat should never be mixed with the grape, the use of spirits should be restricted to meal times, of beer to that of a beverage under normal mental and physical conditions, and wines to social occasions when it is desired to relax the psycho-motor inhibitions.

(7) Solitary indulgence on social and psychological grounds should be discouraged as tending to cause secret drinking and tippling.

(8) As corollary to (7) all bona fide social reformers should encourage the revival and extension of facilities for legitimate indulgence in restaurants, theatres, and other such places, devoted to the alimentary, social, and recreational requirements of the public.

Present Incidence of Alcoholism.

As a matter of historical fact it would appear that alcohol reaches its greatest popularity and use in times of stability and prosperity. Clinical experiences suggests (1) that the general incidence of alcoholism is slightly less than formerly, though not to the extent represented by some propagandists; (2) that the habitual use of alcohol is diminishing to a greater extent; and (3) that the social offence of drunkenness—i.e., inebriation of a disorderly or incapable type—has declined considerably.

FACTORS OF DIMINUTION.

The factors of diminished habitual alcoholism may be tabulated as follows:—

(1) Lessened popularity. Owing to increased mental tension, a relatively short period of exhilaration

or relaxation is produced by alcohol in the present as compared with the Victorian non-addicted population. The tendency in the case of the present generation is to experience more intensely the irritability, discomfort, and confusion of the second stage of inebriation; there is on this account, and to this extent, less habitual drinking. On the other hand, in times of stress and change, mental conflict becomes more intense and universal. This and other factors have widened the range of susceptibility to alcohol, and its use has remained almost as general, though it is relatively less habitual than formerly.

(2) The heavy and prohibitive taxation of alcoholic beverages and other restrictions.

(3) The shorter hours of work and the higher standard of living enjoyed now by that section of the public from which the statistics of old-time police-court drunkenness were drawn.

(4) Increased facilities for young persons for amusements, games, recreation, and adventure—the last being a very important item.

(5) A loosening of conventional restraint between the sexes, and the outlet provided by the freer intercourse thus possible.

(6) The extension of education, and of knowledge concerning the disadvantages of alcoholic excess.

FACTORS OF PERSISTENCE.

The factors which combine to cause the persistence of habitual alcoholism of a morbid degree are:—

(1) Group pessimism and restlessness, due to insecurity and conflict caused by (*a*) economic difficulties—e.g., unemployment, high taxation, &c.—(*b*) the disturbance of social and moral outlook, particularly in sexual and religious spheres.

(2) The encouragement of habits of secrecy and excess through indulgence according to opportunity rather than to necessity, caused by the restriction of hours and places in which alcohol may be openly sold and consumed.

(3) The relatively large increase in drinking amongst women, consequent upon the greater independence and freedom exercised by the sex.

(4) The absence, in Great Britain and Ireland, of amenities such as music and dancing, and of facilities for the use of alcohol socially, in public and with meals, such as abound elsewhere.

(5) The group urge towards individual discipline, sacrifice, and sustained and urgent effort.

(6) The increasing organisation of local transport and movement in the body social and economic, without adequate provision for physiological rest and privacy for the individual.

(7) The inability of most persons to relax at will.

(8) The biological necessity or craving for play and other escapes from reality, and the inadequacy of modern life to provide such escapes.

(9) The social, moral, and political antagonisms which are produced by all biological deprivations compulsorily applied, reasonably or unreasonably, by the group to its members.

THE WATER OF SWIMMING BATHS.

THE outdoor bather in Switzerland is fortunate in having the choice of abundant clean water in many natural lakes. Where he is thrown back on the swimming pool he is faced with the dangers that are now pretty well recognised in this country. A recent writer in the *Gazette de Lausanne* remarks that the tanks of popular swimming baths contain "a veritable purée of bacteria," the numbers of which may reach 40,000 colon bacilli and 130,000 other germs per cubic centimetre. He insists on the special danger of such water to the conjunctiva of the diver and of the exponent of the crawl and other modern strokes involving repeated immersion of the head, as evidenced by the acute follicular conjunctivitis which is peculiar to frequenters of swimming baths, and which appears after six to ten days incubation. The pathogenic agent of this disease is a filter-passing virus, and the clinical and histological aspect of the malady resembles that of trachoma. Although it may last for two to three months the affection however is not serious. The nasopharyngeal mucosa is also often affected by the polluted water of swimming baths. One observer has published statistics of 90 cases of otitis, tonsillitis, rhinitis, laryngitis, pseudo-membranous anginas, and furunculosis of the external meatus, all observed 24–36 hours after swimming in a bath. Another has recorded, in three years, a dozen cases of otitis in "crawlers."

The causes of these dangers are not far to seek, but the writers of this article and of another in the *Feuilles d'Hygiène et de Médecine*, which appears to have inspired it, do not seem to be aware of the success which has been obtained by filtration, followed by chlorination. It is very properly pointed out that filtration is insufficient, and that the sediment consisting largely of desquamated epidermis containing billions of bacteria per cubic millimetre requires a strong dose of chlorine to sterilise it. The plan of removing easily filtrable and coagulable matters and then chlorinating is not discussed. Until a preliminary cleansing with soap and brush can be insisted upon in public as it is in some private baths, the author advises swimmers not to dive or practise strokes *tête dans l'eau*. Finally, the sound advice is given not to confound cleanliness and sport, to wash in washing baths, and when clean to swim in swimming baths. One might have hoped such advice would be redundant, but even in England one has seen rather dirty boys in swimming baths. In the United States of America catchy slogans have been used with some effect.

THE PURPOSE OF AN EXPERIMENT.

A MEDICAL man, who is a director of the Scottish Society for Prevention of Cruelty to Animals, has called our attention to an advertisement which has appeared several times lately in the *Scotsman*, sent by the hon. secretary of an anti-vivisection society, and quoting from THE LANCET of May 24th, 1930 (p. 1120), the following experiment performed by Dr. G. W. Theobald in the course of work on the nature of eclampsia.

> "Bitch, near term; 45 c.cm. of a 4 per cent. solution of potassium oxalate were injected intravenously in three doses of 10, 15, and 20 c.cm. between Jan. 7th and 10th, 1920. The anus was closed on the 9th and the bitch was put on a meat diet. On Jan. 11th the animal refused food; on the 12th it reeled around as if drunk, and on the 13th it went into convulsions. The back was extended, the eyes remained open, and there was a marked tremor of the limbs. The bitch died after the convulsions had lasted one hour and before the pups were born."

The advertisement invites readers to help to stop cruel experiments by subscribing to the funds of the Society. No direct comment is made on the particular experiment, but a reader who saw the advertisement wrote to the *Scotsman* to say: "I regard anti-vivisection as a wrong fad which stands in the way of scientific progress . . . but I cannot see the lesson to be gained from the class of experiment" quoted from THE LANCET. We have asked Dr. Theobald to set out in a few sentences what the experiment was devised to prove, and he replies: "True eclampsia has never been known to occur in a dog. The object of the experiment was to cause intestinal stasis by mechanical means and to lower the blood calcium by the best known non-operative method—i.e., by the injection of potassium or sodium oxalate. The clinical symptoms produced were indistinguishable from eclampsia, and could be relieved by the intravenous injection of calcium chloride." Dr. Theobald adds that the spectacle of a women suffering from eclampsia and the suffering she endures are appalling.

Corrigendum.—The analysis of the death-rate from diabetes mellitus in the United States, annotated in our issue of August 15th (p. 364), appeared in the Statistical Bulletin of the Metropolitan Life Insurance Co. of New York.

STUDENTS' GUIDE—SESSION 1931-1932

THE GENERAL MEDICAL COUNCIL.

POWERS, DUTIES, AND CONSTITUTION.

THE General Council of Medical Education and Registration of the United Kingdom is, first, a registering body: no person, even though his qualifications have been obtained by examination, is a *legally qualified* medical practitioner until his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that there is a definite minimum of medical education and scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner convicted of felony or misdemeanour or adjudged guilty of professional misconduct. Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council consists of 38 members, of whom 18 are appointed by universities and nine by licensing corporations. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives. The Crown members and the university representatives need not be medical men, and one layman now sits on the Council. Three members are appointed for dental business by the Privy Council under the Dentists Act, 1921, under which the powers and duties of the General Medical Council with regard to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the Dental Board of the United Kingdom.

The Educational Curriculum.

Professional Education.—The course of professional study after registration as a student occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

REGULATIONS AS TO REGISTRATION OF MEDICAL STUDENTS.

Before registration as a student every candidate should produce evidence that (*a*) he has attained the age of 17 years; (*b*) that he has passed a recognised examination in general education; and (*c*) that, *in addition thereto*, he has passed, or obtained exemption from, an examination, theoretical and practical, in elementary physics and elementary chemistry conducted or recognised by a licensing body. The minimum standard of General Education required is that of University Matriculation or entrance examination in the Faculties of Arts or Pure Science. In other Faculties the examination must be of the standard prescribed in Regulation 2 below.

An tice. course of instruction in elementary

hospitals, or at the offices of the Council; and should produce proof that he, or she, has fulfilled the first three conditions.

MAINTENANCE OF REGISTER OF MEDICAL STUDENTS.

1. The Education Committee prepares and issues from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are specially recognised by, the Council.

2. The Council has recognised the undernoted university examinations which are conducted in Great Britain and admit to the Faculties of Arts or Pure Science, or to other Faculties, subject to the conditions specified below:—

Oxford University, Responsions; Cambridge University, The Previous Examination. The Matriculation Examinations of the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Victoria of Manchester, Sheffield and Wales, and the Entrance or Preliminary Examination of the Universities of Scotland.

The condition prescribed by the Council in Faculties other than Arts or Pure Science is that:—

The certificate shall bear evidence that the candidate has passed in the Matriculation or Entrance standard, in the following subjects, viz.: (*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English. (*d*) A fourth subject, as defined in the regulations of the particular Examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science, Botany; Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose of matriculation or entrance.

3. Subject to the condition prescribed above (Section 2), the Council will recognise those of the examinations conducted by recognised authorities in Great Britain which are accepted by any one or more of the above-named Universities as equivalent (under prescribed conditions as to "credits" or "grades"), for purposes of Entrance or Matriculation, to an Examination named in the preceding list (Section 2). In School or Leaving Certificates, the four required subjects must have been obtained at not more than *two* sittings. Such Examinations are:—

Bristol University: Higher School Certificate Examination; School Certificate Examination. Cambridge Local Examinations Syndicate: Higher School Certificate Examination; School Certificate Examination. Central Welsh Examination Board: Higher Certificate Examination; School Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: Higher School Certificate Examination; General School Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations: Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

4. The Council will continue to recognise certain Examinations conducted by Educational Bodies, other than those (mentioned in Section 3) whose Examinations are accepted by any one or more of the Universities of Great Britain. Recognition will not be extended under this Section to any Examination unless the Council is satisfied (*a*) that in scope and standard it is equivalent to a recognised Matriculation or Entrance Examination of a University of Great Britain, (*b*) that it fulfils the condition prescribed by the Council (Section 2), and (*c*) that the Examination has been completed at not more than two sittings. Such Examinations are:—

The College of Preceptors (England): Senior Certificate (with *credit*). The Educational Institute of Scotland: Preliminary Medical Certificate.

5. Subject to the prescribed condition (Section the Council will recognise the Entrance Examina to the School of Physic of the University of D and the Matriculation or Entrance Examinati the National University of Ireland, the Quee versity of Belfast, the Irish Royal Colleges of P and Surgeons; and also the Senior Grade o Certificate of the Department of Educati

Irish Free State, the Senior Certificate Examination of the Ministry of Education of Northern Ireland, and all examinations accepted by any one or more of the Universities of Great Britain or Ireland, as equivalent, for purposes of entrance or matriculation, to the above-named University Examinations.

6. Subject to the prescribed condition (Section 2), the Council will recognise all Examinations of Colonial or Foreign Universities which are accepted by any one or more of the Universities of Great Britain as equivalent, for purposes of entrance or matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

7. The Council will recognise the Final Examinations for Degrees in Arts or Science of any University of Great Britain or Ireland or of the British Dominions.

8. The registration of medical students shall be placed under the charge of the Branch Registrars.

9. Each of the Branch Registrars shall keep a register of medical students.

10. The Branch Registrar shall enter the student's name and particulars in the Students Register, and give him a certificate of such registration.

11. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of Great Britain or Ireland of which he is Registrar, blank forms of application for the registration of medical students.

12. A copy of the Medical Students Register prepared by each of the Branch Registrars shall be transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who will distribute the list to the licensing bodies, medical schools, and hospitals.

All applications for special exceptions to the foregoing regulations as to registration shall be addressed to the Registrar of the General Council, and shall be decided by authority of the Education Committee, who shall report thereon to the Council.

MEDICAL SCHOOLS AND COLLEGES.

The Universities, including their Colleges and Medical Schools, and Schools of Medicine at which Medical Study may be commenced in the United Kingdom are set out seriatim in the following pages.

Medical Registration in Ireland.

By agreement between the Governments of Great Britain, of the Irish Free State, and of Northern Ireland — since confirmed by legislature at Westminster and Dublin—the powers and duties of the General Council of Medical Registration and Education are continued as heretofore in respect of qualifying bodies in the Irish Free State, and of medical practitioners qualified in the Irish Free State. Side by side with this a Medical Council has been set up in the Irish Free State with the duty of establishing and controlling a Register for the Irish Free State. Practitioners whose names are on the General Register, and persons who pass a qualifying examination in the Irish Free State, will be registered on the Irish Free State Register on payment of the prescribed fee. The Irish Free State Medical Council have, over those whose names are on the Irish Free State Register, the same disciplinary powers as are possessed by the General Council over those whose names are on the General Register. To possess the privileges of a qualified practitioner in the Irish Free State it is necessary to be registered in the Irish Free State Register.

The net result of the change in the law as regards the practitioner qualifying in the Irish Free State in the future is that: (1) If he intends to practise only in the Irish Free State he need only register in the Irish Free State Register; (2) if he intends to practise in Great Britain he will register in the General Register; and (3) if he is in doubt where he will practise he will register in both Registers. He will, as he registers in one Register, or in both Registers, put himself under the disciplinary control of the one Council or of both Councils. No practical inconvenience is caused, and practitioners qualified in the Irish Free State in future will not find themselves deprived of any of the privileges or rights enjoyed by their predecessors.

Dental Board of the United Kingdom.

Anyone who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available, and, unless registered in the Dentists Register, no dental work, under the additional Benefit Scheme of the National Health Insurance Act can be undertaken.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts.

The Dental Board consists of a chairman and 12 members. The chairman is appointed by the Privy Council. Other members of the Board are appointed by the Minister of Health, the Scottish Board of Health, the Governor-General of Northern Ireland, the General Medical Council (3), Direct Vote of the qualified dentists practising in England and Wales, Scotland, and Ireland (3), Direct Representatives by dentists registered under the Dentists Act, 1921.

REGISTRATION OF DENTAL STUDENTS.

The General Medical Council's Regulations in regard to the registration of dental students which came int force on Jan. 1st, 1923, provide that the registration dental students shall be carried on at the Gener Medical Council Office in London, in the same mann as that of medical students, and be subject to th same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence either at a recognised dental hospital or school, or by pupilage with a registered dental practitioner.

Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in dental mechanics. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school. Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study. When a student can show evidence of regular pupila
that two years in dental mechanics
dental practitioner, prior to the
prescribed preliminary and scientific ex
may be allowed to antedate his regi
period not exceeding one year prior to
these examinations.

MEDICAL EXAMINING BODIES AND SCHOOLS IN ENGLAND AND WALES.*

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M.* and *D.M.*, two in Surgery, *B.Ch.* and *M.Ch.*, and a diploma in *Ophthalmology*. The examinations are open to men and women alike.

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. To obtain the degrees of B.M. and B.Ch. the following examinations must be passed: 1. Preliminary subjects: Physics and Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Honour School of Natural Science; Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Honour School of Natural Science; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine and Public Health, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The first B.M. examination may be passed at any time after the Preliminary Scientific examinations. Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately.

At any time after passing *First B.M. Examination*, the candidate can, on producing certain certificates, present himself for examination in the subjects of Pathology, Forensic Medicine and Public Health, Materia Medica and Pharmacology; but cannot, unless he is already a registered medical practitioner, enter for Examination in Medicine, Surgery, and Midwifery, until the eighteenth term from his matriculation, nor until a period of at least thirty-three months has elapsed from the date of passing the First B.M. Examination. He must pass in Medicine, Surgery, and Midwifery at one and the same time.

Before admission to the Examinations in Pathology and Bacteriology, and Materia Medica and Pharmacology, of the *Second B.M. Examination*, the student must produce certificates of having attended courses of instruction including practical work in Pathology, Bacteriology, Post-mortem Clerking, Pharmacology, and Pharmacy, either in Oxford or in a recognised Medical School. Before admission to the remainder of the second B.M. Examination, he must produce a number of other certificates, including certificates of having acted as Clinical Clerk and Dresser, each for six months in the Wards, of instruction in Midwifery and of attendance on Labours, of instruction in Infectious Diseases and in Ophthalmology, of proficiency in Vaccination and in the administration of Anæsthetics, and of three academic years of hospital practice.

The degree of Bachelor of Surgery (B.Ch.) is granted with that of B.M. after passing the above examinations.

The degree of Doctor of Medicine (D.M.) is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by judges appointed for the purpose by the Board of the Faculty of Medicine. The degree of Master of Surgery (M.Ch.) is granted after examination to Bachelors of Surgery who have entered upon their twenty-first term, and who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Schorstein Research Fellowship of the value of £200 a year, tenable for two years, is offered in alternate years. Candidates must be graduates of the University, under 35 years of age, and must hold a registrable medical qualification. Their research must be carried out in one of the Medical Departments at Oxford. A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects, Animal Physiology, Botany, Zoology. A George Herbert Hunt Travelling Scholarship of the value of about £100 is awarded every second year to enable a Bachelor of Medicine to undertake three months' study abroad. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. Scholarships at certain London hospital medical schools are awarded each year on the nomination of the Regius Professor of Medicine or of the Dean of the Medical School. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships varies, according to the candidate's need, between £30 and £100 a year; the exhibitions vary in value from £30 to £100 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1931–32; from the Regius Professor of Medicine; from the Professors in the departments of medical science; and from the Dean of the Medical School, Oxford.

Radcliffe Infirmary and County Hospital.

There are 265 beds. Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) clinical lectures by the Litchfield Lecturers in Medicine and Surgery; (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation; and (4) pathological demonstrations and instruction in post-mortem work are given by the Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. A post-graduate course is held in the hospital in the autumn of each year.

---

* For special diplomas see p. 435.

UNIVERSITY OF CAMBRIDGE.

There are two degrees in Medicine, *M.B.* and *M.D.*, two in Surgery, *B.Chir.* and *M.Chir.*, and Diplomas in *Public Health, Hygiene, Tropical Medicine* and *Hygiene*, and *Medical Radiology and Electrology.* Students of Girton or Newnham College are admitted to the examinations for these degrees and diplomas.

The student must enter a College, or become a Non-Collegiate student, and keep nine terms (three years) by residence. He must pass the Previous Examination of the University before he comes into residence or therefrom obtain exemption, particulars of which may be obtained from the Registrary. He may then devote himself to medical study in the University. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing the Examinations for the Ordinary B.A. degree, or an Honours degree by passing one or more Tripos Examinations. The Natural Sciences Tripos is taken most frequently by medical students, as some of the subjects are practically the same as those for the First and Second M.B. Examinations.

For the degree of Bachelor of Medicine (M.B.) five calendar years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three years are spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the *First and Second M.B. Examinations.* Hospital practice may be attended at Addenbrooke's Hospital, Cambridge, after the student has passed Parts I. and II. of the *Second Examination.* The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *First* includes (1) General and Inorganic Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *Second* is divided into three parts—viz. (1) Organic Chemistry, (2) Human Anatomy and Physiology, and (3) Pharmacology and General Pathology. The *Third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic. Candidates who have passed both parts of the Third M.B. examination are admitted to the registrable degree of Bachelor of Surgery (B.Chir.) without separate examination and without keeping an Act.

The degree of Doctor of Medicine (M.D.) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five calendar years, and if an M.A. to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis with *viva voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

Candidates for the Degree of Master of Surgery (M.Chir.) who are M.A.'s may be admitted to the examination after they have become legally qualified under the *Medical Acts* to practise surgery. Others may be admitted to the examination when two years at least have elapsed after they have completed all that is required of candidates for the Degree of B.Chir. Candidates are required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject. (The examination is held in February.)

A Diploma in Medical Radiology and Electrology is granted. Candidates must hold a recognised medical qualification. All teaching for the Diplomas in Public Health, in Hygiene, and in Tropical Medicine and Hygiene will cease after Sept. 30th, 1931, and no examinations will be held after April, 1932.

Scholarships and Prizes.—Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors. There are Natural Science scholarships at most of the Colleges and prizes in the ancillary medical subjects. Some of these are entrance scholarships; some may be gained by students already in residence, and where suitable candidates are not forthcoming among such students the emoluments may be allotted to members of other Colleges. Valuable scholarships instituted on behalf of Medicine are the Tancred Studentships in Physic, tenable at Gonville and Caius College. The successful candidates must enter at the college within a month or remove there if they are members of any other college. Students are required to take the degree of M.B. as soon as they are of sufficient standing but may hold a Studentship for a further three years. Thus a student elected previous to admission to college can draw the emolument, the annual value of which is about £100, for eight years. Full particulars can be obtained from Mr. E. T. Gurdon, 28, Lincoln's Inn-fields, London. Among other scholarships and prizes may be mentioned the Balfour Studentship, for research in Biology, of the value of £300 a year for three years, not restricted to members of the University; the Frank Smart Studentship and Prizes for Botany and Zoology, and the Shuttleworth Studentship for Zoology or Physiology tenable at Gonville and Caius College. The one University prize in Medicine, the Raymond Horton Smith Prize, is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a Tripos Examination.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Mechanics, Physics, Biology, Pharmacology, and General Pathology may be obtained upon application to the Registrary, The Registry, Cambridge.

Addenbrooke's Hospital.

Over 200 beds. Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Mr. Vernon Pennell.

UNIVERSITY OF LONDON.

The University of London was constituted in 1836, reconstituted under the Act of Parliament, 1898, as a teaching as well as an examining body, and again reconstituted under Act of Parliament, 1926. All the metropolitan medical schools are constituent colleges, while Clinical Units have been established at St. Bartholomew's, the London, St. Mary's, St. Thomas's, University College Hospital, and the Royal Free.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who are registered as pursuing a prescribed course of study, or an approved course of research, in a school of the University, or under teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. External students in addition to matriculating must register as preparing for an examination leading to a Degree or Diploma within the purview of the Council for external students.

University College.

University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Histology, Physiology, Biochemistry, and Pharmacology (the Intermediate Medical Sciences). Research work is undertaken in all departments. The completion of the building scheme by the erection of the section for Anatomy, Histology, and Embryology, together with further extensions to the Department of Physiology and Biochemistry, which the generosity of the Rockefeller Foundation made possible, provides exceptional facilities for research and post-graduate study in anatomy, physiology, and pharmacology. In particular might be specified the opportunities for investigation in human and comparative embryology and neurology, in histology, radiology, anthropology, biochemistry, and experimental physiology and experimental embryology. Arrangements exist for the close correlation of the work of the Faculty with University College Hospital and Medical School. Women students are admitted.

Scholarships and Prizes.—The first four items on the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (*a*) The Bucknill Scholarship, 160 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (*d*) Entrance Scholarship, £30 a year for three years; (*e*) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, Pharmacology, and Chemistry; (*f*) Schafer Prize in Physiology, £18 triennially; (*g*) Sharpey Physiological Scholarship, £115, Biological Sciences; (*h*) Bayliss-Starling Scholarship, £120 a year, Physiology, Biochemistry; (*j*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £20 a year; and (*k*) five Gold and five Silver Medals awarded annually in various departments. For further information apply to the Secretary, University College, Gower-street, London, W.C.1.

King's College.

The Medical Faculty at this College gives instruction in the subjects of Medical Science for the Preliminary and Intermediate Examinations in Medicine and Surgery, and Dental Surgery, of the University of London and of other Universities and examining bodies, to students entering the College directly, and also to students of the following four hospital schools which prepare only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital. The Faculty is open to both men and women. Special courses in Anatomy and Physiology in preparation for the Primary Examination for the F.R.C.S. (England) are held twice yearly.

Scholarships and Prizes.—Two or more Warneford Entrance Scholarships of £30 each for four years. Examination in April, subjects selected from Divinity, Classics, Science. Sambrooke Scholarship of £30 for three years. Examination in April, subjects selected from Classics, Science. Worsley Scholarships: £100 in five annual instalments of £20. *At the end of the First Year* of study, the Rabbeth Scholarships (£30 and £15), the *Carter* Gold Medal and Prize in Botany, and the Hare Prize in Zoology are open for competition. *At the end of the Third Year*, the Hughes Prize in Anatomy, the Huxley Prize in Physiology, the Inchley Prize in Pharmacology, and the Jelf Medal are open for competition. The Layton and the Berridge Research Studentships (£150 per annum *each*), the Daniell Scholarship in Chemistry (£40), Warneford Prizes (£25 and £15), Leathes Prize, Barry Prize, &c., are also open to Students of this Faculty. The majority of the Scholarships and Prizes are open to Regular Students only. For further information apply to the Dean of the Medical Faculty.

Medical students of the University of London, who are pursuing their medical curriculum in the metropolis will proceed to one of the recognised medical schools connected with the University. At four of these schools the preliminary studies will be taken at King's College, while at the other schools the whole curriculum can be taken out in connexion with the selected hospital. These hospitals are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. Various schools and hospitals are also recognised as schools of the University in special departments, and students may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

The FACULTY OF MEDICINE of the University grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*) and the degree of B.Pharm. (*Bachelor of Pharmacy*); the two higher degrees being open only to candidates holding the M.B., B.S. degrees of the University. The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (*Inorganic Chemistry, Physics, including Mechanics, and General Biology*) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (*Part I.*): *Organic Chemistry.*—This examination will take place twice in each year, commencing on the Thursday following the second Monday in March and on the Thursday following the first Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery, (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital; (14) The conduct of at least 20 Labours; (15) Antenatal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work; (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics, and Gynæcology. The subjects may be divided into two groups, namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. Bachelors of Medicine who graduated before May, 1904, may obtain the B.S. by passing the Surgical part of the M.B., B.S.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis for approval and may be exempted from a part or from the whole of the written examination.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology, and Rhinology. A thesis may be submitted as for M.D.

Doctor of Philosophy.—A Degree of Ph.D. has been instituted in non-clinical subjects for Internal and External Students in the Faculty of Medicine. Candidates for this degree must hold, in a branch of study akin to that in which they propose to proceed to the Ph.D. Degree, the Degree of M.B., B.S., or B.D.S., or B.Pharm., or B.Sc.

Bachelor of Pharmacy.—The course extends over three years.

Full details of the prescribed curricula can be obtained free on application to the Academic Registrar, or for External Degrees from the External Registrar, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

St. Bartholomew's Hospital and College.

The hospital contains 762 beds, of which 692 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electrotherapeutics and X Ray work. Whole-time Clinical Units under Professors of Medicine and Surgery have been established. A new Surgical Block of ten wards, with accommodation for 250 patients, and connected with a block of five new operation theatres is now in use.

Ten house physicians and ten house surgeons are appointed annually, are provided with rooms and board, and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear, and a house surgeon for orthopædic surgery are appointed every six months, and are provided with rooms and board and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students.

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry. *The Medical College Buildings* include three large lecture theatres, a large dissecting-room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is complete. A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. Facilities for research work are afforded in the Clinical Units and Laboratories of pathological and other departments.

Scholarships given in aid of Medical Study.—Six Entrance Scholarships and Exhibitions are awarded annually—viz.: (1) and (2) a Scholarship of £100 and an Exhibition of £60 in any Two of the following subjects: Human Anatomy and Embryology, Physiology, Pathology (including Bacteriology), Biochemistry; (3) a Scholarship of £100 in not fewer than three of the following: Chemistry, Physics, Botany, Zoology, and Physiology; (4) and (5) a Scholarship of £100 and the Jeaffreson Exhibition of £50 in Mathematics, Latin, or Greek or French or German, a second Language or Chemistry or Physics;

---

[1] Of these schools that of the Royal Free Hospital is reserved for women; University College and King's College admit men and women, the former limiting the number of women when clinical work is reached; the remainder admit men only.

(6) the Shuter Scholarship of £50 in Anatomy and Physiology, which is awarded after competitive examination among Cambridge Graduates. The more important of the other Scholarships and prizes are as follows:—Four Junior Scholarships—(7) No.1, £30, Anatomy and Physiology (8) No. 2, £20 Anatomy and Physiology; (9) No. 3, £25, Chemistry, Physics, and Biology; (10) No. 4, £15, Chemistry, Physics, and Biology; (11) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (12) Kirkes Scholarship, £30 and medal, Clinical Medicine; (13) and (14) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (15) Sir G. Burrows Prize, 10 guineas, Pathology; (16) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (17) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (18) Luther Holden Research Scholarship in Surgery, awarded by election, £105; (19) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115; and (20) Baly Scholarship in Clinical Medicine, £75, awarded by examination.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Information may be obtained on application to the Dean of the Medical College, Mr. W. Girling Ball.

Charing Cross Hospital.

The Hospital, to which the School is attached, contains 300 beds, shortly to be increased by a number available for paying patients. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X ray work, and for Electrical Treatment. In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Six House Physicians, six House Surgeons, two Obstetric and Gynæcological House Surgeons, and six House Surgeons to the Special Departments are appointed annually. The following appointments are open to students after they have held resident appointments: Resident Medical Officer, at a salary of £400 per annum; Registrar to the Medical, Surgical, Obstetrical, and Ear, Nose, and Throat Departments, at £150 per annum.

Primary and Intermediate students to receive their lectures and practical work at King's College, and final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged in general and special subjects.

At an Institute of Pathology, with a whole-time staff of scientific workers and fully equipped laboratories, students receive their training in Preventive Medicine, Pathology, and Bacteriology, with special facilities for research, and post-graduate teaching is available. The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Courses in General Medicine, Surgery, and Pathology, with the requisite Clinical work in the wards and out-patient departments are provided for students reading for Dental qualifications.

The Pathological Museum, containing over 4000 specimens and 3000 histological preparations, comprises (1) The Section on General Pathology, and (2) the Cuthbert Lockyer Collection of over 1150 Gynæcological and Obstetrical specimens.

The Library contains 3950 volumes.

The Students' Club, with smoking and luncheon rooms on the school premises, cloak room, telephone, &c., provides for the social comfort and convenience of the students. The club is controlled by a committee of students, and includes the Medical Society and the Dramatic Society. The *Gazette* is published quarterly. The sports ground, of 13 acres, at Colindale, provides facilities for Rugby and Association football, cricket, hockey, and tennis (hard and lawn courts). In addition there are sections of the club devoted to athletics, boxing, swimming, and golf.

Scholarships.—The following are offered annually: (*a*) For students commencing medical studies—two scholarships, each of the value of £50; (*b*) for students commencing clinical studies—two "University" scholarships, each of the value of £120, in Pathology; one "University" scholarship, value £120, and one "Open" scholarship, value £75, in Anatomy and Physiology. In addition there are a number of Exhibitions.

Prizes.—(1) The "Llewellyn" Prize, £25, for highest distinction throughout final course of studies; (2) "William Travers" Prize, £15, Midwifery and Gynæcology; (3) "Pereira" Prize, £4 4*s*., Clinical commentary; (4) "T. H. Green" Prize, £5 5*s*., Clinical commentary; (5) Clinical Surgery Prize, £3 3*s*.; (6) "John H. Morgan" Prize, £13; (7) "Steadman" Prize in Pathology; (8) Numerous class prizes and medals; and (9) The Governor's Clinical Gold Medal.

Further information may be obtained on application to the Dean, Mr. Eric A. Crook, M.Ch., F.R.C.S., or to the Secretary of the School.

St. George's Hospital.

This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. There are all the usual special clinical departments. One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds. Children's beds are placed in the women's wards. There are two ophthalmic wards.

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £250 per annum each; Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum; Medical Registrarship at £200 per annum, Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £100; the post of Resident Anæsthetist at £100.

Entrance Scholarships and Endowed Prizes of a total value of £908 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at that College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Scholarships and Prizes.—At this school 11 entrance scholarships and exhibitions are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively; (*c*) and (*d*) two Anne Selina Fernee Scholarships, £80 each; (*e*) Devitt-Pendlebury Scholarship, £50; (*f*) and (*g*) two Anne Selina Fernee Exhibitions, £60 each, Anatomy and Physiology, except in the case of (*c*) and (*f*) subject of examination for which is General Pathology.

In addition to the above Exhibitions, each of the value of £40 and up to four in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*h*) Allingham Scholarship in Surgery for Students qualified not more than two years, £87; (i) and (*j*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing; (*k*) H. C. Johnson Memorial Prize, £20, Practical Anatomy; (*l*) Pollock Prize, The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright. Certain Research Scholarships of £200 each are awarded annually to students working in the departments of the institute; and research beds have been instituted. Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the Medical School, including ten salaried posts with salaries varying from £200 to £750 per annum. A special Post-graduate course is held during the first week-end in October, and is open to all General Practitioners and other qualified men without fee.

Entrance Scholarships.—Two Entrance Scholarships of the value of £210 each are awarded annually, by nomination in July, the Geraldine Harmsworth Scholarship, £200, and one or more University Scholarships of £200 are awarded in July.

The Athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains. A large pavilion has recently been added.

Rebuilding of the Medical School.—Building operations began in August, 1930, and the foundation stone was formally laid by H.R.H. the Duchess of York in June, 1931. It is hoped that the buildings will be ready for occupation at the end of 1932. The new School will contain departments for the teaching of all Preliminary and Intermediate subjects, and will include a student's club, dining and billiard rooms, and a gymnasium and swimming bath.

For further information apply to the Dean of the Medical School.

Middlesex Hospital.

The hospital and cancer wing contain over 470 beds, with special wards for Cancer, Maternity, Gynæcological, Otological, Neurological, and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin; Nervous Diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electro-therapeutic department and a department of Radium Therapy and Research. The Cancer Wing, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electrotherapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

All appointments are made without fee of any kind, and the following are appointed at intervals annually: eight house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one senior resident anæsthetist, two junior resident anæsthetists, and four resident officers to the special departments. Ten registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

The Medical School, which includes the Bland-Sutton Institute of Pathology, the Courtauld Institute of Biochemistry, the Barnato-Joel Laboratories, and the Ferens Institute of Otology, is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, for the Diplomas in Public Health, and the University of Cambridge Diploma in Radiology, for which two courses are held yearly. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 Professors, 26 recognised Teachers, 10 Demonstrators, 4 Tutors. The Bland-Sutton Institute of Pathology and the Courtauld Institute of Biochemistry are completely equipped for routine hospital investigations, teaching and research work, and contain large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility.

Other features of interest are: the course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone, Prof. J. McIntosh, and Prof. W. B. Tuck. A primary F.R.C.S. course is held twice yearly, and also special classes to prepare students for the Intermediate Examinations of the Universities.

Scholarships and Prizes.—Two Entrance Scholarships, value £100 each, and two University Scholarships, value £90 and £60, are awarded annually in September. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship is awarded annually on the nomination of the Headmaster of Epsom College. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5*s.*; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas. There are numerous class prizes.

The Students' Amalgamated Clubs include the following: Medical Society, Common Room Society, Musical Society, cricket, football, rowing, chess, lawn tennis, hockey, sailing, and fencing. There are a restaurant and a gymnasium in the school buildings, and athletic grounds at N. Wembley. Squash racquets.

For further particulars apply to the Dean or the Secretary of the Medical School.

St. Thomas's Hospital.

This Hospital contains 644 beds. There are special departments for the treatment of women, children, diseases of the eye, ear, nose and throat, skin, teeth, and for orthopædics. Nervous and mental diseases are treated in special departments. An electrocardiograph has been installed for the investigation of diseases of the heart. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for Radiology, Electrotherapy, Phototherapy, Massage and Remedial Physical Exercises are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. Clinical Units in Medicine and Surgery have been established.

All appointments in the hospital are open to students without extra fee. Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward and district, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists.

The arrangements are made to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of *London* and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments.—A Resident Assistant Physician and a Resident Assistant Surgeon, salary £225 each per annum, and a Resident Anæsthetist, salary £200 per annum, are appointed annually. Three medical and four Surgical Registrars at a salary of £250 rising to £300 hold their appointments on a tenure renewable to a maximum of four years. A Pathological Registrar to the Department of Obstetrics and Gynæcology (at an annual salary of £250), an Ophthalmic Registrar (at an annual salary of £200), and an Orthopædic Registrar (unpaid) are appointed yearly. Eight Resident Casualty Officers and Anæsthetists are appointed every six months. Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months. Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for reelection. There are three Assistants in the Department of Pathology; the Senior receives £600 a year, and the two Juniors £450 each.

Scholarships and Prizes.—At this school there are the following Entrance Scholarships—namely, one in Arts, equivalent to the tuition fees for the first two years of study; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in any two of the following: Anatomy, Physiology, Pathology, Chemistry, also the "Hector Mackenzie" University Exhibition of the value of £60. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship each for third-year students and tenable for two years, £35 each; (*d*) Mead Medal, Medicine, Pathology and Hygiene; (*e*) Wainwright Prize, Medicine; (*f*) Toller Prize, Medicine; (*g*) Cheselden Medal, Surgery and Anatomy; (*h*) Clutton Memorial Medal in Clinical Surgery, biennial; (*i*) Beaney Scholarship, £50, biennially, Surgery and Surgical Pathology; (*j*) Solly Medal and Prize, biennial, Reports of Cases; (*k*) Sutton Sams Prize, biennial, Report of Cases; (*l*) Bristowe Medal, Pathology and Morbid Anatomy; (*m*) Hadden Prize, Pathology and Morbid Anatomy; (*n*) Grainger Testimonial Prize, £31 10*s*., Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology.

St. Thomas's House, the New Students' Club, comprises spacious dining-, smoking-, and reading-rooms, and accommodation for some 60 resident students. There is no occasion for students to leave the hospital premises during working hours.

Further information may be obtained from the Secretary of the Medical School, St. Thomas's Hospital.

University College Hospital.

The final subjects in the curriculum are taught at the Medical School of the hospital, which has 526 beds, including 74 in the new obstetric hospital. The course of instruction is suitable for the examinations at the Universities of Oxford, Cambridge, Durham, and other British Universities, and for the medical education required by the Examining Board in England and the Society of Apothecaries. Clinical Units in Medicine, Surgery, and Obstetrics and Gynæcology are now in operation. The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Out-patient Department of the hospital. The department of otology, rhinology, and laryngology (the Royal Ear Hospital) has been provided with a separate building in Hunter-street, adjacent to the obstetric hospital. It contains 39 beds, including eight private wards for patients of limited means. The hospital is equipped with all modern appliances for investigation. The new buildings of the Obstetric Hospital of 74 beds (rendered possible by the Rockefeller Benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension to the Nurses' Home, and new research laboratories for the Medical School are now finished and in full occupation. Twelve women students are admitted annually.

Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Sixteen house physicians, ten house surgeons, ten obstetric assistants, four house surgeons to the Royal Ear Hospital (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification. All house officers reside free in the hospital. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: Resident Medical Officer, Surgical Registrar, Medical Registrar, Obstetric Registrar, Harker-Smith Cancer Registrar, Ophthalmic Registrar, Registrar to the Royal Ear Hospital, Casualty Medical Officer and a Casualty Surgical Officer, Assistants in Ear and Throat, Skin and Venereal Diseases Departments, and House Anæsthetist.

Assistants to Medical, Surgical, and Obstetric Units.—These salaried appointments which have come into existence recently at the same time as the creation of the whole-time Chairs in Medicine, Surgery, and Obstetrics, are of great value to senior students who may desire to remain at Hospital after holding the ordinary resident appointments. They enable a man to continue clinical work and also to devote time to laboratory or other research, so as to fit himself for higher posts in the profession. The salaries range from £250 up to £600 a year, resident quarters being provided only for the chief assistant to the Obstetric Unit. The total number of such Assistantships varies from time to time, being generally about 12, and an aggregate sum of about £5000 annually is available for their salaries.

Scholarships and Prizes (those in connexion with University College have already been enumerated).—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Scholarships, 112 guineas each, two of the following subjects: Anatomy, Physiology, General Pathology; (*e*) Goldsmid Entrance Exhibition, entitling holder reduction by £80 in the fees due for the full course of Final Medical Studies, two of the following subjects: Anatomy, Physiology, General Pathology; (*f*) Filliter Entrance Scholarship, entitling the holder to a reduction by £52 10*s*. in the fees due for the full course of Final Medical Studies; (*g*) Graham Scholarship in Pathology, £300 per annum for two years, awarded by the Senate of the University of London; (*h*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*i*) Atchison Scholarship, tenable for two years, £55 per annum, General Proficiency in Medical Studies; (*j*) Magrath Clinical Scholarship, about £150, Clinical Cases; (*k*) Percival Alleyn Scholarship, about £75, Surgery; (*l*) Filliter Exhibition, £30, Pathology; (*m*) Erichsen Prize, £21 1*s*., Practical Surgery; (*n*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*o*) two Liston Gold Medals for Clinical Surgery; (*p*) Alexander Bruce Gold Medal for Pathology and Surgery; (*q*) Tuke Silver and Bronze Medals for Pathology; (*r*) Radcliffe Crocker Travelling Scholarship for Dermatology; and (*s*) Leslie Pearce Gould Travelling Scholarship for Surgery. A limited number of Bursaries are available from the Atchison Fund, awarded at the discretion of the Dean, to enable students whose means do not allow to take Resident Posts.

The *Museum of Pathological Anatomy* is open for study daily, and microscopic sections of most of the specimens have been prepared and are available for the use of students on application to the Curator. The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee. The Medical Library, open daily to every student of the School, contains about 20,000 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the Medical School are required to become members. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet courts in the Medical School, and the Athletic Ground at Perivale.

University College Hall, Ealing, is recognised by the authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge.

Full information can be obtained from the Dean of the School.

Westminster Hospital.

The Hospital contains 248 beds, and has attached to it a Radium Clinic with 22 beds, elaborately equipped for all forms of Radium Therapy and Research. There are separate departments for diseases of the eye, skin, teeth, ear, nose and throat, for orthopædic practice, for diseases of women, for diseases of children, for radiography, for venereal disease, and for massage, electrical and light treatment. The anatomical, pathological, and materia medica museums are open to all students of the School.

The entire teaching of the Hospital is devoted to the subjects of the Final Examinations. Arrangements are made for the tuition required for Preliminary and Intermediate subjects.

Appointments: Paid appointments as Medical, Surgical, and Obstetric Registrars, Casualty Officers, House Physicians, House Surgeons, Anæsthetist, &c., are available for students when they have passed their examinations.

Research: There are excellent opportunities for Research work in the recently endowed John Burford Carlill Laboratories. Grants to assist Research workers are made annually from the John Burford Carlill Endowment.

Fees: Annual fee, £40. An entrance fee of 10 guineas includes membership of the Sports Union Club with its various branches—i.e., football, cricket, tennis, boxing, and Guthrie Society. The Athletic Grounds are situated in Tooting and are reached in 20 minutes from the hospital.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £75 each. Summer Session: Two Scholarships in Anatomy and Physiology, £75 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Reports on Cases; Chadwick Clinical Surgery Prize, £5, Reports on Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology 5 guineas, a Paper and Tests in Practical Work; Hanbury Prize in Diseases of Children, 10 guineas; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students —Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship £20, Elementary Anatomy, Physiology, Histology and Organic Chemistry; Daniell Scholarship, £40, Chemistry; Rabbeth Scholarships open to First-year Students, one of £30 and one of £15; Class Examinations in the Preliminary Scientific Course. Inghley Prize in Pharmacology, £5, open to Students who within two years of passing the first examination for medical degrees have completed the course in Pharmacology. Hare Prize in Zoology, £2 10*s*., open to First-year Students. Inquiries should be addressed to the Dean of the Medical School.

London (Royal Free Hospital) School of Medicine for Women.

The Royal Free Hospital contains 280 beds. The Hospital also has large Casualty and Out-patient Departments. A Children's Department, including 18 cots, an Orthopædic Department, and a Light Department have recently been added to the Hospital. Maternity Districts are attached to the Unit operating in the Gray's Inn-road and Essex-road areas. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital, Queen-square, South London Hospital, and Royal London Ophthalmic Hospital.

A Clinical Unit in Obstetrics has been established controlling 68 beds. Courses are arranged for the Primary Fellowship Examination of the College of Surgeons. The Eastman Dental Clinic, for which Mr. George Eastman, of Rochester, N.Y., has provided the building fund, provides dental treatment. The course for dental students is in conjunction with the Royal London Dental Hospital, Leicester-square.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

Students' chambers are provided in the neighbourhood of the school and the Warden can be consulted on the subject.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants, clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics.

Scholarships and Prizes.—Among the larger of these awards are the following :—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years. (*d*) Bostock Scholarship, tenable for two or four years, £90. (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30; Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1931, £16. (*i*) John Byron Bursary, tenable for two years, for students already in the School requiring assistance for the prosecution of their medical studies; application to the Secretary by March 31st next, £20. (*k*) Helen Prideaux Prize and Julia Ann H. Cock Prize, to be spent in assisting the newly qualified holder to further study, £60 each. (*l*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, open to all medical women, preferably coming from India, or going to work in India. (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1931. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s.* a year, awarded in alternate years; next award in July, 1931. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July 1932. (*p*) Alfred Langton Scholarships, tenable two years, one awarded annually, £50 a year. (*q*) School Jubilee Bursary, tenable for three years, £50 a year. (r) Flora Murray Bursary, awarded every year to a fifth-year student, £50. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery. The Students' Union arranges the social, athletic, and other clubs and societies.

Inquiries may be addressed to the Warden and Secretary of the Medical School, 8, Hunter-street, London, W.C.

UNIVERSITY OF DURHAM.

The University of Durham grants degrees of Bachelor of Medicine; Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, Doctor of Hygiene, Bachelor of Dental Surgery and Master of Dental Surgery, a Diploma in Public Health, Diploma in Psychiatry, and a Licence in Dental Surgery.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Biology and Organic Chemistry. The subjects of the Second Examination are—Anatomy and Physiology. The subjects of the Third Examination are—Pathology and Bacteriology, Materia Medica, Pharmacology and Pharmacy, Medical Jurisprudence, and Public Health. The subjects of the Fourth Examination are—Medicine, including Therapeutics, Clinical Medicine, Surgery, Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Psychological Medicine, Diseases of the Skin, of the Throat, Nose, and Ear, and of Children, and Ophthalmology. It is required that at least one of the five years of professional education shall be spent at the University of Durham College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special examination in the subjects of Medical Anatomy, Medical Pathology, and the Principles and Practice of Medicine. The subjects of examination for the M.S. are—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates must not be under 40 years of age and must have been in active practice for 15 years as registered medical practitioners. They must also produce certificates of moral character from three registered members of the medical profession. The fee is 50 guineas (including the degree fee), of which 20 guineas is retained if the candidate fails to satisfy the examiners.

Attention is particularly directed to the fact that the Senate of the University on the 4th February, 1930, decided that this examination should not be held after June, 1932.

Doctor of Surgery.—The University of Durham grants the Degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, and not less than 25 years of age. They must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery and ancillary subjects. One at least of the three years must be spent in the University. The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology, and Bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Candidates for any of the above degrees, diplomas, or licence must give at least 28 days' notice to the Secretary of Examinations, University of Durham College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before April 1st.

Scholarships and Prizes.—The following are awarded :—University of Durham Entrance Scholarship, £25 a year for four years; Pears' Entrance Scholarship, £10 a year for three years (awarded every third year); Heath Entrance Scholarship (from Kepier Grammar School), £60 (renewable); Province of Durham Masonic (Entrance) Scholarship, £60 (renewable); Heath Scholarship for Surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year

The following Scholarships are tenable for one year, namely :—Tulloch Scholarship for Elementary Biology and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology, Gold Medal and £20; Charlton Scholarship for Medicine, £25; Gibb Scholarship for Pathology, £28; Luke Armstrong Scholarship for Comparative Pathology, £25; Stephen Scott Scholarships for Anatomy and Physiology, two of £50 each; Philipson Scholarships for highest marks in Final M.B., B.S. Examinations, two of £35 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £325; Hamilton Drummond Memorial Scholarship, in aid of research in Clinical Surgery, about £50; Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy; and Outterson Wood Prize for

Psychological Medicine, £10; Sewell Memorial Prize and Silver Medal for Clinical Pathology.

For further information apply to the Dean of the College.

Newcastle-upon-Tyne: College of Medicine.

Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 600 beds, and there are facilities for the study of the various special subjects.

Practical midwifery can be studied at the Princess Mary Maternity Hospital, which contains 90 beds, with an annual indoor and outdoor attendance on 3000 cases.

The bacteriological laboratory is adjacent to Armstrong College.

Post-graduate Instruction.—A comprehensive series of post-graduate courses have been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study afforded by the College, the Royal Victoria Infirmary, and the Princess Mary Maternity Hospital; and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer sessions and an intensive course in the summer vacation.

A *Students' Union* has been erected and furnished at a cost of over £54,000, and is now in daily use. Special accommodation has been provided for women students.

Royal Victoria Infirmary.

The Infirmary has over 600 beds. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are given by the Assistant Physicians, Assistant Surgeons, the Medical and Surgical Registrars, and the Assistant to the Gynæcological Department, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, and Venereal Disease, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory in which all clinical bacteriological investigations are carried out. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1931 opens on Oct. 1st, and the summer session of 1932 on April 12th. Applications for detailed information should be made to the Sub-Dean, Dr. Horsley Drummond, at the hospital.

Appointments of assistants in the pathological and other special departments and of clinical clerks and dressers are made periodically. Resident appointments are also made every six months; and each year medical and surgical registrars (who also act as tutors) are appointed from candidates who have previously held resident appointments at any recognised hospital. These latter posts afford an excellent opportunity for post-graduate study, not only at the Infirmary, but also in the departments of anatomy, physiology, pathology, and bacteriology of the college.

Practical Midwifery is studied at the Princess Mary Maternity Hospital, which has 90 beds and a large extern department. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health.

Post-graduate Instruction.—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Venereal Diseases; Neurology; Diseases of Children; Electrotherapeutics and Radiology; special courses in Midwifery will be held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the early part of the Summer Vacation. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, and also at the Princess Mary Maternity Hospital, for specified periods.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees, including the subjects of Physics, Chemistry, and Biology, extends over six years. The Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Physics, Chemistry, Biology, and Organic Chemistry; but at least three years must be spent in attendance upon classes in the University. The final year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. Before commencing the study of Anatomy and Physiology, examinations in Chemistry and Physics and Biology must be passed (First M.B., Ch.B., Parts I. and II.), or examination in lieu thereof. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. Second Examination.—Part I., Organic Chemistry; Part II., Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology. Fourth Examinations (at the end of the fifth year).—Forensic Medicine and Toxicology; Public Health; and Materia Medica, Pharmacology, and Therapeutics. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery and Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months. Vaccination instruction must be taken and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery. Distinctions may be awarded in the subjects (severally) of the Second, Third, Fourth, and Final; and First- and Second-Class Honours in the Final Examination.

Degrees of Doctor of Medicine and Master of Surgery. At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D. and one in Principles and Practice of Surgery, including operations on the cadaver, for the Ch.M., or, at the discretion of the examiners, in a special branch of Medicine or Surgery respectively. A thesis of exceptional merit may exempt from any part of these examinations, in which Honours may be awarded.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year candidates may carry on research elsewhere, under approved conditions, and on completing the course present a thesis and submit themselves for oral and possibly written examination.

Scholarships and Prizes.—The following are awarded:—Entrance Scholarships: (*a*) Frank Fletcher and Catherine Fletcher Scholarships of £100 per annum each, for five years. Two or more offered annually; open to men and women students under certain prescribed conditions as to residence, &c.; (*b*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*c*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*d*) Dental Scholarship of £46 17*s*. 6*d*., Open Competitive Examination in subjects learned during apprenticeship; (*e*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland (available for year 1931–32); (*f*) two Ingleby Scholarships of £10 each, awarded to the candidates at Final Examination obtaining highest marks in the subjects of Midwifery and Diseases of Women; (*g*), (*h*), (*i*), and (*j*) Four Queen's Scholarships of £10 10*s*. each, awarded to the candidate taking the first place in the Second, Third, Fourth, and Final Examinations respectively, provided that the candidate's work is sufficiently distinguished; (*k*) Priestley Smith Prize in Ophthalmology, value about £6 10*s*., is awarded annually to the student passing the Final M.B., Ch.B. Examination on first entry who shows the best knowledge of Ophthalmology, provided the Examiners deem him worthy of this distinction; (*l*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*m*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the Student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal for Medicine) is awarded annually to the candidate taking the highest place in Clinical Medicine and passing the Final M.B., Ch.B. Examination in June; and the "Sampson Gamgee Memorial Medal" (Gold Medal for Surgery) is awarded annually to the best candidates passing Final M.B., Ch.B. Examination in June in Surgery (paper, oral, and clinical). The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in fourth and fifth years, open to all students.

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital, Queen's Hospital, Maternity Hospital, Children's Hospital, Mental Hospital, and Fevers Hospital, under the direction of the University Clinical Board. Appointments are open to students varying from £40 to £200 a year.

Post-graduate Instruction.—A "William Withering Lectureship" has been established. A course (or courses) of lectures is given annually for post-graduates on subjects chosen from year to year. In 1932 the Lectures will be given by Mr. G. J. Bond, C.M.G., F.R.C.S., F.L.S. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers. The Lecturer for year 1932 is Prof. Seymour Barling, C.M.G., M.S., F.R.C.S. (Joint Professor of Surgery, University of Birmingham). Post-graduate Courses of Clinical Demonstrations for General Practitioners are arranged annually (April to July) at the Birmingham General, Queen's, and Children's Hospitals.

Queen's Hospital.

There is a close association of this Hospital (330 beds) with the University of Birmingham, and the University clinical teaching is conducted here, there being a wealth of excellent material. Ward rounds and out-patient clinic classes are held daily, and there are regular tutorial classes throughout the session. Post-graduate courses arranged by the University are conducted every year. There are special departments in Gynæcology, Diseases of the Eye, of the Ear, Nose and Throat, Dentistry, Radiology, Pathology, Bacteriology, Biochemistry, Physiotherapy, Electrocardiography, and Psychiatric Clinic associated with the Birmingham Mental Hospitals authorities. There are also large Wards for Midwifery and Postnatal cases, a Nursery for instruction in Infant Welfare, an extensive Midwifery District and residential facilities for students. There are 23 Resident Appointments (exclusive of Registrars) available each year for recently qualified students.

Birmingham General Hospital.

There are 484 beds. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, and Septic cases; special beds for Eye and Skin cases. Laboratories for Bacteriology, Biochemistry, Cancer Research, and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Six operating theatres (one for outpatients and one for casualty department, which is a separate department), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electrotherapy, Electrocardiographic investigation, and Venereal Diseases. Post-graduate classes in every branch of medicine and surgery. The Jaffray Branch Hospital contains 61 beds.

Birmingham and Midland Eye Hospital.

There are 115 beds. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available. A limited number of Non-Resident Clinical Assistants' posts are open to qualified practitioners, particulars of which can be had on application to the General Superintendent. This Hospital has a very large Out-Patient Department.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Doctor in Philosophy (Ph.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Matriculation.—Candidates for the degrees in Medicine and Surgery are required (*a*) to have satisfied the examiners in the several subjects of the Matriculation examination or to have passed such other examination as may from time to time be recognised for this purpose by the Joint Matriculation Board; (*b*) to have included Mathematics among the subjects in which they have passed at such examination.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least two of the six years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The subjects of the First Examination are: (1) Chemistry; (2) Biology (Zoology and Botany); (3) Physics; (4) Special Chemistry. The subjects of the Second Examination are: (1) Anatomy; (2) Physiology (including Physiological Chemistry and Histology). The subjects for the Final Examination are: (1) (*a*) Pathology, (*b*) Pharmacology and General Therapeutics; (2) (*a*) Forensic Medicine and Toxicology, (*b*) Public Health; (3) (*a*) Obstetrics and Diseases of Women, (*b*) Surgery, Systematic, Clinical, Operative, and Practical, including Ophthalmology, (*c*) Medicine, Systematic and Clinical, including Therapeutics, Mental Diseases, and Diseases of Children. Candidates may take Parts (1), (2), and (3) separately, provided that they do not present themselves for Part (3) until they have completed the sixth year of medical study.

Degrees of Doctor of Medicine and Master of Surgery. No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least two years have elapsed since he passed the examinations for those degrees. Candidates may also take the degree of Doctor of Medicine by examination after five years from taking Liverpool M.B., Ch.B. Candidates for the degree of Doctor of Medicine, who elect to present a thesis, are required (*a*) to present a thesis, acceptable to the Faculty, and certified to be the candidate's own work, together with (if the candidate desires) copies of published original papers upon Medical Science; (*b*) to present themselves for an oral examination on the subject of the thesis.

The subjects of examination for the Degree of Master of Surgery are: Surgery, Clinical Surgery, Operative Surgery, Surgical Pathology and Bacteriology, and Surgical Anatomy.

The University also awards a *Diploma in Medical Radiology and Electrology*—Part I., Physics; Part II., Radiology and Electrology. The parts may be taken at one examination or separately.

Scholarships, Fellowships, and Prizes.—The following are awarded: (*a*) Robert Gee Entrance Scholarship (Men), annually, of £42 10*s.*, tenable for four years; (*b*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects; (*c*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination on results of Professional Examination in Anatomy and Physiology; (*d*) Derby Exhibition of £15, Competitive Examination in Clinical Surgery; and (*e*) Clinical School Exhibition of £15 in Clinical Medicine; (*f*) University Scholarship of £50 for one year, awarded on results of the Final (Part I.) Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £150 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Biochemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £200, for one year; (*m*) Ethel Boyce Fellowship in Gynæcology, of £100, for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; (*p*) Lady Jones Research Fellowship in Orthopædic Surgery, £200; (*q*) Samuels Memorial Scholarships, three at £20; (*r*) Ridgway Research Scholarship (£100); numerous prizes and medals.

The Medical School.—All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. There is also a separate building for Tropical Medicine. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation.

Clinical Studies.—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women (with the Samaritan Hospital), Liverpool Maternity Hospital, the Royal Liverpool Children's Hospital, and St. Paul's Eye Hospital. These hospitals contain in all a total of about 1500 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the Victoria University of Manchester—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine, a Diploma in Public Health, a Diploma in Bacteriology, and a Diploma in Pathology, are awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M.B. Examination.

The First Examination: (1) Chemistry and Physics; (2) (*a*) Botany, (*b*) Zoology. Candidates must have attended, during at least six months, courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1. Inorganic and Elementary Organic Chemistry and Physics; Part 2, (*a*) Botany, (*b*) Zoology. The candidates sit for these parts separately. The Second Examination: (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. Both parts must be passed simultaneously. The Third Examination: (1) Pharmacology and Materia Medica; (2) Pathology and Bacteriology. The Final Examination: (1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine; (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts: Part I., Forensic Medicine, Hygiene and Preventive Medicine; Part II., Medicine, Surgery, Obstetrics and Gynæcology (Systematic, Clinical, and Oral). The two parts of the Final Examination must each be passed as a whole. Candidates for the Second Part must have completed the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery of this University and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation, or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery of this University, and at least one year had elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Degrees of B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in Medicine who in their third year of study for the degree of M.B., Ch.B., complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in Anatomy or Physiology, who are students in Medicine, are required to attend courses in advanced Anatomy and Physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science may proceed to the degree of M.Sc. by presentation of an approved thesis.

Diplomas: 1. The following are available for candidates holding a registrable qualification in medicine, surgery, and midwifery; examinations are in two parts in each diploma and are written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination:—

(*a*) *Diploma in Psychological Medicine.*—Part-time course: extending over three University terms, two of which must be spent at the University. Six months' residence must be spent at a recognised Hospital for Mental Diseases.

(*b*) *Diploma in Public Health.*—The course extends over twelve calendar months at least: Part I. of the examination is held in June and October, and Part II. in March and October. Instruction for at least one of the parts must be taken out at the University. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

2. *In Veterinary State Medicine.*—Length of course, three University terms. Candidates must be members of the Royal College of Veterinary Surgeons.

3. *In Bacteriology.*—For candidates who have graduated either in science or medicine, or obtained other approved qualification. Length of course, one academic year. A satisfactory thesis on an approved subject must be presented.

4. *In Pathology.*—For candidates who have obtained a registrable medical qualification or other qualification approved by the Senate. Length of course, one academic year. A satisfactory thesis on an approved subject must be presented.

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at the Victoria University:—Scholarships: Dreschfeld Entrance (triennial), £20; John Russell Medical Entrance, £45; Sam Gamble Entrance for Women; Graduate Entrance (fees up to 100 guineas); two Dauntesey Medical Junior, £50 each; Dauntesey Medical Senior, £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology; Platt Physiological, £90; Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100; Holt Post-Graduate Medical Scholarship for Women, £60; Elected Research Studentships; Fellowships: Leech Research, £70; Professor Tom Jones, Surgical, £105; Morrison Watson in Anatomy, £150; John Henry Agnew in Diseases of Children, £120; Delépine in Preventive Medicine (biennial), £300; Worswick (Causes and Treatment of Rheumatoid Arthritis), £300; Pilkington Fellowship in Cancer Research, £300; Zimmern Travelling Fellowship for Men, £175, also for Women; Knight Fellowship in Psychological Medicine; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology—Junior £10, Senior £20; Wild Prize in Pharmacology, £10; Turner Medical, two prizes each of 10 guineas; Dumville Surgical, £15; John Henry Agnew in Diseases of Children, £30. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories (now removed to special buildings close to the Royal Infirmary) ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped as part of a new department for investigation in cancer. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica; new Pharmacological Laboratories were added last year. In the public health department, which is lodged in a separate institute in York-place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, mental hospitals, a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Post-graduate Studies.—Post-graduate Courses in the following subjects have been arranged for during 1931–32, in addition to those usually held at the various hospitals: 1. Whole-time intensive course in Obstetrics. 2. A Post-graduate Day. 3. Part-time courses in (i.) Diseases of the Eye, (ii.) Diseases of the Skin, (iii.) Practical Instruction in Local Anæsthesia and Minor Operative Surgery, (iv.) Practical Clinical Medicine. 4. Clinical Assistantships. 5. Radium Therapy. Syllabuses and other information may be obtained on application to the Dean of the Medical School, Manchester University.

Manchester Royal Infirmary.

The Manchester Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 644 patients (including 54 beds at the Central Branch). The medical side consists of four units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing, and apparatus rooms, and its own class-room attached. All of these units are occupied. The gynæcological, aural, and out-patient departments each have their own operating theatre. Bacteriological investigations are carried out in a special clinical laboratory. A department for the study of heart disease, with an electric cardiograph and other instruments for research, diagnosis, and teaching purposes is attached to the medical wards. There is also a laboratory for clinical research. In the educational block is a large lecture theatre and a museum. In the same building is housed the X ray department, which has nine separate X ray outfits for different purposes, and in which one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with this department.

Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 132 beds; and (2) the Central Branch in the City, which has accommodation for 54 patients. The Associated Hospitals thus contain 776 beds and are under the same management. Women students are admitted on the same terms as men.

Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

Royal Manchester Children's Hospital.

The hospital, which is situated at Pendlebury, near Manchester, contains 190 beds and 30 in the Convalescent Home, Lytham St. Anne's. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary, Gartside-street, Manchester. There is a Massage and Electrotherapeutic Department, also an Artificial Sunlight Department. Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is an Orthopædic Department. Out-patients' day for which is on Tuesday, at Gartside-street, and a ward at Pendlebury is devoted to these cases needing operative treatment. Out-patients are seen daily at 9 A.M. at the Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

Ancoats Hospital, Manchester.

There are 114 beds with a Convalescent Branch of 35 beds at Great Warford, Alderley Edge, Cheshire. The hospital, founded in 1828, will be extended during the next two years by the addition of a new ward block, an operating theatre block, pathological department, physiotherapeutic department, and lecture theatre.

The medical division consists of three units served by consultative out-patient clinics. One unit includes a cardiological department; another devotes special attention to gastro-enterology; and the third to neurology. The surgical division comprises an orthopædic unit in which all the fractures and injuries of the hospital are treated; a unit devoted particularly to urology; a unit devoted to abdominal surgery; and an oto-laryngological unit. All units include out-patient clinics. A special clinic staffed by a team consisting of surgeons, pathologist, radiologist, and consultant in radium therapy has recently been created for the study and treatment of malignant disease. The demand on the surgical in-patient accommodation is great, 800 patients at the present time being on the waiting-list. Clinical teaching is given both to undergraduate and post-graduate students in all out-patient clinics, in the wards, and in the form of special lectures. The under-graduate teaching includes a University course in Orthopædic Surgery given in the Michaelmas term, and demonstrations on the examination of the ear, nose and throat. The hospital takes an important share in the University of Manchester Post-graduate scheme. A post-graduate "day," open to all practitioners without fee, is held on each Thursday in the University terms. Special intensive post-graduate courses are held from time to time. Applications for entry to these courses should be made to the Dean of the Faculty of Medicine, University of Manchester.

There are six residents: a resident surgical officer, a resident medical officer, three house surgeons, and one house physician. These appointments are open both to men and women graduates, and are recognised by the University of London for the purposes of the M.D. and M.S. degrees. There are also four registrar appointments (part time): medical, orthopædic, surgical, and pathological. These are made annually, and are renewable up to a period of three years. General Supt. and Secretary: Herbert J. Dafforne.

Manchester Northern Hospital for Women and Children.

The hospital, situated at Park-place, Cheetham Hill-road, Manchester, contains 73 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine. Courses and Degrees in the Faculty are open to men and women alike.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination. The First Examination consists of: Part I., Physics and Inorganic Chemistry; Part II., Zoology and Botany; Part III., Organic Chemistry. Candidates will be allowed to pass the parts separately. The Second Examination consists of: Part I., Materia Medica and Practical Pharmacy; Part II., Anatomy Physiology. Candidates will be allowed to pass either part separately. The Final Examination consists of: Part I., Pharmacology, Pathology, and Bacteriology; Part II., Medicine, Surgery, Obstetrics, Gynæcology, and Clinical Pathology; Part III., Forensic Medicine, Public Health, and Therapeutics. Part I. may be taken at the end of the second clinical year, and Parts II. and III. may be taken at the end of the third clinical year, but not before the completion of the fifth year of medical study. If taken separately Part II. may be passed before Part III.

Degree of Doctor of Medicine and Master of Surgery.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least two years' Hospital Practice or four years' other professional practice for the former, and one year has elapsed for the latter since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine may present a dissertation and, if the dissertation is considered to be of exceptional merit, will not be required to pass an examination. The first term commences on Oct. 1st. Prospectus can be obtained from the Academic Sub-Dean.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods, or post-graduate classes held by members of the clinical staff, may do so on application to the Clinical Sub-Dean, from whom particulars may be obtained.

Clinical Studies.—The clinical studies are pursued mainly at the LEEDS GENERAL INFIRMARY, which has accommodation for 630 in-patients, including 88 beds at branch hospitals in the country. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electrotherapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification. Further particulars concerning these, and the scholarships and prizes open to competition, may be obtained from the Dean of the Faculty of Medicine.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are *Bachelor* of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation, and have pursued the courses of study required by the University regulations during a period of not less than five and a half years subsequently to the date of his matriculation, three of such years at least having been passed in the Faculty of Medicine of the University one at least being subsequent to the passing of the Second Examination. The subjects of the First Examination are Chemistry, Physics, and Biology. Candidates who have passed the Intermediate Examination in the Faculty of Pure Science, including any or all of the subjects of the First Examination, will be considered to have passed the latter examination when they have passed in such of its subjects as they did not take for the Intermediate B.Sc. Examination. Such candidates shall be required to pay the fee for the First Examination. *Candidates must*, in addition to matriculation, pass a preliminary examination in Physics and Chemistry before taking *the First* Examination, for which they must have *attended* courses of instruction (lectures and laboratory work) in Chemistry, Physics, and Biology *for one year each.* The Second Examination: Candidates must have attended courses of instruction in Physiology (first part) for one year, and in Anatomy *for five terms.* The Third Examination: Candidates must have attended courses of instruction in Pathology for five terms, in Pharmacology for four terms (and one term in Pharmacy), in Applied Anatomy for four terms, and in Physiology (second part), for six terms. The Final Examination: The subjects are, Part I., Forensic Medicine and Public Health. Candidates must have attended courses for one term in each subject; Part II., Medicine (including Mental Diseases, Diseases of Children, and Vaccination), Special Pathology (including Morbid Anatomy and Clinical Pathology), and Therapeutics; Part III., Surgery (including the administration of Anæsthetics, Diseases of the Ear, Nose and Throat, Ophthalmology, and Surgical Pathology), and Obstetrics and Gynæcology, including Antenatal and Postnatal practice and Infant Hygiene. *Candidates for Parts II. and III.*, must have completed a minimum of five and a half years of approved study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least three years previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least three years previously, and must since have held for not less than twelve months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology and Bacteriology.

Scholarships and Prizes.—The following scholarships are offered: Four Town Trustees scholarships offered annually, each of the value of £50 per annum for three years. Medical: offered annually, covers cost of tuition for a degree course in the Faculty of Medicine. Six Edgar Allen, offered annually, each of the value of £125 per annum for three years. Post-graduate: Frederick Clifford scholarship, value £50 per annum, tenable for two years. Mechanics' Institute scholarship, value £50 for one year with free admission to those University courses taken by the holder in connexion with his work, renewable for a second year. Town Trustees fellowship, value £75 for one year. Medals and Prizes: Kaye scholarship; Thomas Woodcock Prize; Gold Medal in Clinical Medicine and Surgery; John Hall Gold Medal in Pathology; Holroyd Gold Medal in Anæsthetics; the Walter S. Kay Gold Medal in Mental Diseases; bronze medals. Particulars of all the above may be obtained from the Registrar.

The Medical School.—The Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain meals and refreshments at moderate prices. The University journal *The Arrows*, edited by a committee of staff and students, is published each term. The University Halls, "Oakholme," Clarkehouse-road; "Tapton Cliffe," Fulwood-road, and "Endcliffe University Hall," Endcliffe Vale-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained from the tutor for women students. Stephenson Hall is a hall of residence for men students; particulars may be obtained from the Warden.

Clinical Studies.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes.

The Sheffield Royal Infirmary (500 beds) provides all the opportunities of a large general hospital with special departments for Skin and Ear. The Sheffield Royal Hospital, 340 beds, has special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. The two institutions are amalgamated for the purposes of clinical practice, medical, surgical, and special. There are special departments for the treatment of Diseases of the Eye, with wards assigned to them, at both hospitals, and excellent junior appointments. The Jessop Hospital for Diseases of Women, with 146 beds, has also a Maternity department, with about 900 in-patients per annum and about 3000 out-patient cases attended. The Children's Hospital has 92 beds. Special courses on Fevers are held at the City Fever Hospitals (988 beds) and on Mental Diseases at the South Yorkshire Mental Hospital (1900 beds). Every facility is afforded in the various laboratories for the prosecution of advanced studies and research.

Post-graduate Courses.—Post-graduate courses of clinical instruction are held annually in the various hospitals connected with the School.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass, at Matriculation standard, an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics and entering on the professional curriculum at the University, or an institution recognised as equivalent, of which three shall have been passed in the University, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations. The First Examination: The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.) The Second Examination: The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). The Final Examination: The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine and Toxicology. Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). The subjects included in Part II. may be taken in two groups—viz., Group I., Surgery and Obstetrics; Group II., Medicine, Public Health, Special Pathology, Forensic Medicine and Toxicology. Candidates may pass Parts I. and II. together, or separately, and the two groups of Part II. may be taken together or separately. Forensic Medicine and Toxicology may be taken with Part I., or with Group II. of Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—The degree may be taken in General Surgery or in Special Subjects. Candidates shall be Bachelors of not less than two years' standing as such. For General Surgery, they shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and in Operative, Clinical, and General Surgery, and shall present a dissertation. For Special Subjects—i.e., Ophthalmology or Oto-rhino-laryngology or Gynæcology, they shall, in addition to having studied and practised for two years the subject concerned, have held an approved appointment in it for not less than six months; they shall pass a written, oral, and clinical examination in the branch of Surgery concerned, as well as in the Anatomy, Physiology, and Pathology of the region of the body concerned (including in the case of Ophthalmology Physiological optics) and also a written examination in the principles of General Surgery.

Clinical Studies.—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 660 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments. The Bristol Royal Infirmary has now been selected by the National Radium Commission as a Radium Centre.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High-frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 100 beds, and that of the Bristol Eye Hospital with 40 beds. Other institutions, including the Bristol Mental Hospital, Southmeed Hospital, Ham Green Fever Hospital, Stoke Park Colony for mental defectives, and the Winford Orthopædic Hospital, are also available for their special purposes.

There are numerous salaried junior appointments for residents who are graduates.

Scholarships and Prizes.—The following are awarded: The Ashworth Hallett Scholarship, value £40, open to women only; two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 7 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology; the Crosby Leonard Prize, value 6 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10*s*., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose, and throat, value £17; Lady Haberfield Scholarship, value about 25 guineas;

the Paul Bush Gold Medal in alternate years to best Resident Medical Officer at Royal Infirmary; Markham Skerritt Memorial Prize, awarded every three years to that member of University, not a member of Medical Board, who, in opinion of that Board, has published the best original work during the three years.

Bristol City Senior Scholarships and those offered by the Counties of Gloucestershire, Somerset, Wilts, and Dorset, and the City of Bath are tenable in the University. The Beaverbrook Fellowship and some of the Fellowships awarded by the Colston Research Society for research in the University are allotted to the Faculty of Medicine.

Post-graduate Study.—Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Demonstration courses with weekly lectures are held from October to June inclusive.

All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

The University grants Degrees in Medicine, and Diplomas in Public Health and Tuberculous Diseases. Preliminary courses of study for the Degrees in Medicine may be pursued at any of the constituent Colleges of the University—viz., at Aberystwyth, Bangor, Cardiff, or Swansea. The Welsh National School of Medicine is situated in Cardiff. All classes are open to both men and women students.

Particulars may be obtained on application to the Registrar of the University of Wales, University Registry, Cathays Park, Cardiff, or to the Secretary, Welsh National School of Medicine, The Parade, Cardiff.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

CONJOINT EXAMINING BOARD.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England, and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Students are required to pass a Preliminary Examination in General Education recognised by the Board, and a *Pre-Medical Examination* in Chemistry, Physics, and Elementary Biology conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognised by the *Board*—namely, the examination in Chemistry, Physics, and Biology for the degree in Medicine of any University recognised by the Board; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. Not more than two terms of professional study (Anatomy and Physiology) will be recognised before Elementary Biology is passed. He will be admitted to the examination on producing evidence of having passed the required preliminary Examination in General Education. The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months. The fee for the examination is £4 4*s.*, for re-examination in Chemistry £2 2*s.*, re-examination in Physics £1 1*s.*, and re-examination in Biology £1 1*s.*

There are two Professional examinations called the *First* and *Final Examinations.* The courses of study for these examinations may be commenced before the Pre-Medical examination in Biology or some equivalent examination has been passed, provided that three terms of study are completed after the examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology. (*b*) Physiology, including Biochemistry. Section II. Pharmacology and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including Biochemistry during five terms, courses of instruction in Pharmacology, and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination, provided that the courses for Section I. have been completed. The fee for the First Professional Examination is £10 10*s.*, for re-examination after rejection in Section I. £6 6*s.*, for re-examination after rejection in either part of Section I. £3 3*s.*, for re-examination after rejection in Section II. £3 3*s.* A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology), and Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. The fee for admission to Section I. is £4 4*s.*; for admission to Section II., Part I., £10 10*s.*; Part II.,

£10 10*s.*; Part III., £6 6*s.*; and the re-examination fees are respectively £3 3*s.*, £6 6*s.*, £6 6*s.*, and £4 4*s.* Members of recognised universities outside the British Possessions are admissible to the examinations of the diplomas of L.R.C.P. and M.R.C.S., under special conditions. Graduates in medicine and surgery are required to pass the first examination and to complete 12 months hospital practice before admission to any part of the final examination. Undergraduates are required to complete the full curriculum of 33 months for the final examination after having passed the first examination. For further information see the current regulations of the Conjoint Examination Board in England.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First Examination may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, in Laryngology and Otology, and in Gynæcology and Obstetrics. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, London, W.C.1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years. The alteration in the by-law of the College is designed to enable men who have just finished house appointments to sit for an examination for which their recent clinical experience has exactly fitted them. The candidate must either have obtained the licence of the College, or a degree of Doctor or Bachelor of Medicine at a University which is registrable by the General Medical Council and is recognised by the Censors Board. The examination is directed partly to pathology and partly to the practice of medicine. Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German. Further information may be obtained from the Registrar at the College. The fee for admission as a Member of the College is 40 guineas, except when the candidate for membership is a licentiate of the College, in which case the fee already paid for the licence is deducted from the 40 guineas. The fee for the examination is 10 guineas, which is reckoned as part of the fee for admission in the case of success.

Fellowship.—Fellows are selected annually from the ranks of Members by the Council of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce, and include the examination of patients and the performance of operations on the dead body. The First Examination is held in June and December and the Second Examination in May and November.

The fees for examination are: First Examination, first admission 8 guineas, and for each readmission 5 guineas. Second Examination, each admission 12 guineas. The fee payable on admission to the Fellowship by Members is 10 guineas and by non-Members 30 guineas, in addition to examination fees.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First Professional Examinations of the English Conjoint Board in Anatomy and Physiology, or the equivalent examination in his University, on the production of certificates of attendance upon prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination on producing evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, London, W.C.1.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS.[1]

The College was founded and incorporated in September, 1929. The objects of the College are set forth in the Memorandum of Association. The first, a very important object, is "To encourage the study and practice of Obstetrics and Gynæcology, subjects which should be inseparably interwoven."

The College consists of Fellows and Members, and has power to take part in the Examination of Candidates for admission to the British Register of Medical Practitioners, in coöperation with teaching and/or examining bodies authorised to conduct medical examinations for the purpose of qualifying candidates for admission to the British Register of Medical Practitioners, if invited by such bodies. It also has power to grant diplomas and certificates in Obstetrics and Gynæcology, either alone or in coöperation with teaching and/or examining bodies authorised to grant such diplomas.

Candidates for the Membership of the College have to show evidence of having held resident appointments in general medicine or surgery, and also in Obstetrics and Gynæcology, before entering for the examination. The Fellowship of the College is granted to those Members who are judged by the College to have advanced the science and art of Obstetrics and Gynæcology. The Fellowship and Membership of the College includes practically every teacher of Obstetrics and Gynæcology in Great Britain, and many distinguished exponents in the British Dominions.

It is hoped that in a few years' time one of the essential qualifications for election to the staff of all departments of Obstetrics and Gynæcology in general and in special hospitals will be the Fellowship or Membership of the College. Consequently, all intending to specialise in these subjects should endeavour to obtain as soon as possible the Membership, the conditions and regulations of which may be obtained from the Hon. Secretary, Prof. W. Fletcher Shaw, 20, St. John-street, Manchester.

---

[1] The British College is placed with the English Corporations, but its advantages are open, as are those of the English Colleges to all who can comply with the regulations.

SOCIETY OF APOTHECARIES OF LONDON.

The Pre-Medical and Primary Examinations are held quarterly. The Pre-Medical includes Chemistry, Physics, and Elementary Biology. The Primary includes Anatomy, Physiology, and Histology, Materia Medica, and Pharmacy. The latter examination cannot be passed before the completion of 12 months' Practical Anatomy with Demonstrations, and the first two subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final Examination for the Licence (L.M.S.S.A. Lond.) is held monthly, except in September. (*a*) Principles and Practice of Surgery, including Surgical Pathology, Surgical Anatomy, Operative Manipulation, Instruments and Appliances. (*b*) Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, Bacteriology, and Morbid Histology. (*c*) Midwifery, Gynæcology, Diseases of New-born Children, and the Use of Obstetric Instruments. (*d*) Forensic Medicine, Hygiene, Mental Diseases, and the Theory and Practice of Vaccination. The examination is partly written, partly practical, partly clinical, and partly oral. Sections *a*, *b*, *c*, and *d* may be taken at separate examinations, but there is no exemption from any part of the Final Examination. (A separate examination in Pathology will be instituted during the current year.)

The minimum period of medical study extends over five years, and three academic years (33 months) must elapse after a candidate has passed the examination in Anatomy and Physiology before he can complete the *Final Examination*. The course of study for the Final Examination includes attendance on the Surgical and Medical Practice with Post-mortem Examinations, at a hospital connected with a medical school for a period of three winter and three summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The office of dresser or clinical clerk must have been filled at a hospital or institution recognised by the Society.

The certificates prescribed by the Regulations must be produced before admission to the respective sections of the Final Examination.

Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Pre-Medical Examination is five guineas, and for the Licence 20 guineas, which may be paid in two instalments of ten guineas.

Master of Midwifery.—The examinations for this Diploma are held in May and November. Candidates will be admitted to the examination who have been registered practitioners for at least one year and who have held a resident appointment in an institution recognised by the Society for six months or more, and who for three months in each case have attended an antenatal clinic and an infant welfare centre, also recognised by the Society. Medical officers employed by a public health authority, and having special duties connected with Maternity and Child Welfare, will be admitted to the Examination on production of evidence to that effect. Until 1932 practitioners of ten years' standing may enter for the examination without further formality than the production of satisfactory evidence that they have made a special study of the subjects The examination will be conducted by written papers and by clinical and oral tests.

The entrance fee for the examination is £10 10*s*., and a further fee, which at present is fixed at £10 10*s*., must be paid before admission to the Mastery by those who have satisfied the examiners.

Candidates for the examination must send in their certificates to the Registrar, who will supply any other information.

The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Registrar, Society of Apothecaries of London, Blackfriars, E.C.4.

METROPOLITAN CENTRES AFFORDING POST-GRADUATE FACILITIES.

Certain organisations and institutions provide for the needs of the medical student in his curriculum and for the post-graduate student requiring special forms of instruction and opportunities for clinical observation. Many of the institutions are recognised by the English Conjoint Examining Board as a place of study for the fifth year of the curriculum.

Special Diplomas in public health, tropical, psychological, and ophthalmic medicine, medical radiology and electrology, laryngology, otology, and tuberculosis are now granted in proof of intensive work along the different lines indicated. Of these, the Diploma in Public Health, being regulated by the General Medical Council, is registrable. Appointments to and promotion in the various Services are largely dependent on the possession of a particular diploma, and each syllabus of the special courses available at the institutions which follow, either with or without association with the Fellowship of Medicine, is planned to afford the necessary instruction.

The Special Diplomas are dealt with fully on p. 495, where the Bethlem Royal Hospital, the Maudsley Hospital, and the Diploma in Psychological Medicine are referred to. Similarly the Hospitals of the Metropolitan Asylums Board provide post-graduate as well as under-graduate facilities, while the hospitals of the Seamen's Hospital Society both supply the instruction necessary for the Diploma in Tropical Medicine and Hygiene, and coöperate in the activities of the Fellowship of Medicine and Post-Graduate Medical Association.

Infectious Hospitals of the London County Council.

These hospitals, of which there are 18 in the metropolis and the near vicinity, were transferred on April 1st, 1930, to the Council from the Metropolitan Asylums Board, which ceased to exist on March 31st, 1930, under the provisions of the Local Government Act, 1929. The Council holds classes of instruction in fevers at all the infectious hospitals at which ordinary medical students attend, but the only hospitals to which classes of instruction for the Diploma in Public Health are attached are the North Western Hospital and the Brook Hospital. This course of lectures and demonstrations (three months) on clinical practice and in hospital administration is given at the North-Western Hospital, Lawn-road, Hampstead, N.W.3, by the medical superintendent, on Mondays and Wednesdays, at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning Wednesday, Oct. 1st. This course complies with the requirements of the revised D.P.H. regulations of the General Medical Council. Application for further information should be made to the Medical Officer of Health, London County Council, Public Health Department, (Special Hospitals), Victoria Embankment, London, E.C.4.

Seamen's Hospital Society.

The Society possesses seven establishments: the *Dreadnought* Hospital at Greenwich, 250 beds; the Albert Dock Hospital, E.16, 53 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, W.C.1, 75 beds; Tilbury Hospital, Tilbury Docks, Essex, 92 beds; Queen Alexandra Memorial Hospital, Marseilles, 60 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds; and the Angas Home, Cudham, 30 beds. Total, 616 beds. It has also a Dispensary at Southampton, from which patients are transferred to the hospitals. Courses of operative surgery and surgical pathology are arranged by the London School of Clinical Medicine at the Dreadnought Hospital. Post-Graduate Courses for Ship Surgeons are organised by the Society, Part II. (Tropical Medicine and Hygiene) being held at the Hospital for Tropical Diseases, commencing June 15th, and Part III. (Refresher Course in clinical subjects) at the Dreadnought Hospital, Greenwich, commencing July 6th.

The clinical teaching of the London School of Hygiene and Tropical Medicine is given at the Society's Hospital for Tropical Diseases, Endsleigh-gardens, W.C.1.

The Fellowship of Medicine and Post-Graduate Medical Association.

Some 50 general and special London hospitals work in conjunction with this Association, which has its office at Room 28 in the House of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1. Arrangements are made for courses in medicine and in surgery, occupying the whole or part of each day for periods of one to four weeks. Fees, £1 1*s.* to £7 7*s.* Special evening courses for the M.R.C.P. and F.R.C.S. (Final) Examinations are organised at intervals. Series of weekly (free) lectures (during the winter months) and clinical demonstrations in medicine and in surgery (except during August and September) are also arranged. Membership of the Fellowship is open to all qualified medical practitioners, the membership fee being 10*s.* per annum, which includes the subscription to the monthly *Post-Graduate Medical Journal.* The provisional list of Special Courses for 1932 is now available. Full information regarding the courses of study can be obtained from the Secretary.

GENERAL.

Royal Northern Group of Hospitals.

The Royal Northern Hospital, Holloway, London, N.7, is the main institution of the Royal Northern Group of Hospitals, which includes the Royal Chest Hospital, City-road, E.C., Grovelands Hospital (Recovery Branch), Southgate, and the Reckitt Convalescent Home, Clacton-on-Sea. The total number of beds in the group is 455. Besides the honorary staff, there are six anæsthetists, three pathologists, resident medical officer, three resident house physicians, three resident house surgeons, two resident casualty officers, and one resident obstetric surgeon. The large rectangular and circular wards, each of which contains 25 beds, the maternity ward and children's ward for children under 5 years of age, the observation wards in the new Casualty Department, the six operation theatres, and out-patient department are designed with a view of offering the greatest facilities for clinical work. The Special Departments include the following: Fracture, orthopædic, genito-urinary and neurological, physicotherapeutic, pathological (under a director of clinical pathology), tuberculosis, venereal diseases, and X ray (recently remodelled). Patients are removed to the Recovery Branch by ambulance a few days after operation. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. A new maternity department has been opened, and the light department has been re-equipped. A complete hospital for paying patients has just been completed.

Weekly lectures by members of the hon. medical and surgical staff are free to all medical practitioners. Special classes and demonstrations are being arranged for post-graduates. They include instruction in general medicine and surgery, and also lectures and demonstrations in special subjects at the Royal Northern and Royal Chest Hospitals.

Prince of Wales's General Hospital.

This hospital, situated in Tottenham, is in the midst of a densely populated neighbourhood, and contains medical, surgical, gynæcological, and children's wards, having 200 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are six resident medical officers, and clinical assistants are appointed under certain conditions. Special intensive post-graduate courses are also held at intervals throughout the year. Further particulars in regard to the hospital may be obtained from Dr. S. C. Shanks, Secretary to the Medical Committee, 87, Harley-street, W.1; or from Mr. T. H. C. Benians, F.R.C.S., Dean of the College, at the Hospital.

West London Hospital.

This hospital has 220 beds. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in the Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms. The hospital has a fully equipped pathological laboratory. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Sir Henry Simson, at the Hospital, Hammersmith, W. Secretary of the Post-Graduate College, Mr. C. Cole, and of the Hospital Mr. H. A. Madge.

London Temperance Hospital.

The hospital (Hampstead-road, N.W.) contains 136 beds. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Monday, 1.30 P.M.; Tuesday, 10.30 A.M.; Wednesday, 2 P.M.; Thursday, 8 A.M.; Friday, 11 A.M. Out-patient Departments for special diseases have been opened: Diseases of the Stomach and Disorders of Digestion, Dermatology, Ophthalmology, and Oto-rhino-laryngology.

Hampstead General and North-West London Hospital.

In-patient Department: Haverstock Hill, N.W.; Out-patient Department: Bayham-street, Camden Town (138 beds—viz., 109 free, 8 isolation and observation, &c., and 21 paying or contributory). Serves Hampstead and the populous districts of Kentish Town and Camden Town. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients' Department, Bayham-street, Camden Town. Further particulars from the Secretary at the hospital. There is a Post-graduate School free to the medical practitioners of the district. The hospital is also associated with the Fellowship of Medicine.

Metropolitan Hospital.

This hospital has 150 beds, 15 of which are reserved for children. The adult accommodation includes special wards for the reception of Hebrew patients. Operations are held in the afternoons daily, except Saturdays and Sundays. The out-patient department is a large one, and has facilities for the treatment of all diseases; special departments comprising: Neurological, Ophthalmic, Rectal Diseases, Diseases of Women, Genito-Urinary, Diseases of the Throat and Ear, Eye and Skin, Electro-Therapeutics, Dental, and V.D. Attached to the hospital is a Tuberculosis Dispensary for patients from the boroughs of Hackney and Stoke Newington. Further particulars may be obtained from the Secretary of the Medical Committee (Mr. C. Naunton Morgan, F.R.C.S.), or from Mr. Herbert F. Rutherford, the House Governor, at the hospital, Kingsland-road, E.8.

Queen Mary's Hospital.

This hospital has developed from the West Ham and Eastern General Hospital. It has 216 beds and ministers to a very poor public. Founded as a dispensary in 1861, and developing into a hospital in 1890, steady extensions have been made during this century. A Royal Charter was obtained in 1917, and the hospital has become a valuable charity with a full medical staff of physicians and surgeons, and specialists for gynæcology, obstetrics, ophthalmological surgery, radiology, and dental surgery. The Fellowship of Medicine and Post-Graduate Medical Association make frequent use of the opportunities here offered. A Radium Officer has recently been appointed as a supply of Radium has been sent to the Hospital by the King's Fund. The hospital has also appointed an Orthopædic Surgeon to set up a new Orthopædic Department, and in addition, a Dermatologist has been appointed to look after the new Skin Department. The number of beds has increased from 213 to 216 by virtue of the fact of the building and opening of a new Isolation Block for the Maternity Wing. Particulars may be obtained from Major Raphael Jackson, Secretary, Queen Mary's Hospital, Stratford, E.15.

NEUROLOGY.

National Hospital, Queen-square.

The hospital, with the Convalescent Home at East Finchley and branch at Clapham Park, contains 265 beds and cots. The out-patient physicians attend every Monday, Tuesday, Wednesday, Thursday, and Friday at 2 P.M., and the physicians daily. Clinical clerks are appointed under physicians and clinical assistants to out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held three times every year, usually commencing in January, May, and October, and lasting eight weeks. Special Courses in Neurological Ophthalmology, Neuropathology, and the Anatomy and Physiology of the Nervous System are given. The Pathological Laboratory is available for special work under the Pathologist.

West End Hospital for Nervous Diseases.

This institution is recognised by the University of London and by the Conjoint Board as a school of instruction in Neurology for the M.D. degree, Branch III., and for the D.P.M. The Out-patient Department is in Welbeck-street, W.; the In-patient Department is at Gloucester-gate, Regent's Park, and contains 78 beds. Completely equipped with pathological and other special departments, the hospital offers every facility for instruction in Neurological subjects. In conjunction with Bethlem Royal Hospital it offers courses of instruction for the D.P.M. The hospital coöperates with the Fellowship of Medicine in the programmes of special post-graduate teaching organised by the Association. Appointments as Hon. Clinical Assistants in the Out-patient Department are open to registered medical practitioners. Senior and Junior Resident House Physicians are appointed for a period of six months in the first place with remuneration at the rate of £150 and £100 per annum, respectively. The Savill Memorial Prize (value £15) and Medal are offered biennially for competition among post-graduate students who have attended the practice of the hospital or any special course. Full particulars may be obtained from Dr. C. Worster-Drought, Dean, or J. P. Wetenhall, Secretary, 73, Welbeck-street, W.

Hospital for Epilepsy and Paralysis.

This hospital in Maida Vale, W., contains 88 beds, including 20 private wards and 6 pay beds. Both in-patient and out-patient departments are open free to students, as well as to medical graduates. The out-patient department is open every week-day except Saturday at 2 P.M.

HEART AND LUNGS.

Royal Chest Hospital.

The Royal Chest Hospital, City-road, E.C. (associated with the Royal Northern Group of Hospitals, see p. 460), is the oldest chest hospital in London. It has accommodation for 84 in-patients and a large out-patient department, where out-patients are seen daily at 2 P.M., except Saturdays. Special departments include Thoracic Surgery, Laryngology, Radiology, Electrocardiograph, Massage and Physical Exercises, and an Ultra-Violet Light clinic. Clinical Assistants are appointed to work with the physicians in the out-patient department. The Tuberculosis Dispensary for Islington South is attached to the hospital.

Brompton Hospital for Consumption and Diseases of the Chest.

The hospital contains 350 beds. The recent provision of 25 (surgical) beds in a special block has increased the total number up to 350 (approximately). The sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six house physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. An additional month may be spent at the Sanatorium. Pupils are admitted to the practice of the hospital. Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical assistants are appointed to the physicians in the out-patient department and clinical clerks to the physicians in the wards. The medical practice of the hospital is recognised by the English Conjoint Board and also by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital is open to post-graduates and students. Two special post-graduate courses are held during the year. For undergraduates, four courses of eight demonstrations are held throughout the year before each final Conjoint Board examination. For further particulars application should be made to the Dean, Dr. W. J. Fenton.

Mount Vernon Hospital.

The hospital contains 150 beds, Surgical. Clinical Demonstrations are given by the visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards. Diagnostic and follow-up departments, 14, Riding House-street, W.1.

City of London Hospital for Diseases of the Heart and Lungs.

Special Departments: Surgical, Laryngological, Radiological, Pathological, Electrocardiographic. Assistants are appointed to the Clinics, and a limited number of research workers to the Pathological Department. The in-patients staff visit generally in the afternoon; out-patients at 2 P.M. Graduates are admitted on payment of fees which entitle them to attendance at clinics, post-mortem demonstrations, and operations. Special demonstration and lecture courses are provided, and a club room. Graduates desiring Assistantships in any department should address applications to the Head of that department. A Tuberculosis Dispensary (Boroughs of Bethnal Green and part Hackney) is established at the Hospital, Victoria Park, E.2.

National Hospital for Diseases of the Heart.

The practice of the hospital (founded 1857), both in the wards and out-patient department, is open daily to post-graduates and others. Systematic courses of instruction, with lectures and clinical demonstrations, are arranged during the winter and summer sessions; in addition an intensive course, of a fortnight's duration, takes place in January, July, and October of each year. The hospital is fully equipped with all the modern instruments for the investigation of the diseases of the cardiovascular system, and facilities exist for those requiring practical instruction in electrocardiography, X rays, and other graphic methods. Clinical Assistants in the out-patient department are appointed from time to time. The hospital is situated in Westmoreland-street, London, W.

DISEASES OF WOMEN AND CHILDREN.

Hospital for Sick Children.

This hospital in Great Ormond-street, W.C., contains 252 beds. The practice is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to eight medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Clinical Clerks are appointed once a month. In the pathological department facilities are afforded to post-graduates for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology, and in Medical Biochemistry in the Pathological and Biochemical Laboratories. Courses of eight to ten Lecture-Demonstrations are given at weekly intervals twice a year in both subjects (Clinical Pathology and Bacteriology, and Biochemistry.). Time spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, as well as by the English Conjoint Board as part of the final curriculum. These appointments are open to students of all recognised medical schools. In addition, special courses are held from time to time (generally in May and October), as well as routine post-graduate instruction daily.

Queen Charlotte's Maternity Hospital and Midwifery Training School.

This hospital, formerly Queen Charlotte's Lying-in Hospital, is situated in Marylebone-road, N.W. The hospital receives over 2500 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. They also receive valuable instruction in the Antenatal Department, where over 4000 patients attend yearly. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and maternity nurses are received and specially trained. A Residential College provides accommodation for students and qualified practitioners (both men and women), and is opposite the hospital, with which it is in telephonic communication.

Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council.

The Isolation Block (30 beds) for Puerperal Fever and Puerperal Pyrexia, which has been built on the new site at Ravenscourt Park, Hammersmith, was opened for the reception of patients in September, 1930, and the Research Laboratories, which have been erected adjoining this block, are now in full working order.

Students may attend the clinics conducted by the staff at the Isolation Block.

Royal Waterloo Hospital for Children and Women

This hospital, founded at the date indicated by its title, has within recent years undergone considerable extensions and has now 130 beds, while the latest buildings include a Nurses' Home, a new Operating Theatre, and private pay beds. It has a full staff of surgeons, physicians, and gynæcologists, and also special departments. Amongst the many new additions to the equipment of the hospital is an Electrocardiograph apparatus. A new Orthopædic Department is in use, and the Physiotherapeutic and Electrical Department has been extended and re-equipped. There are facilities for post-graduates to attend the general and special clinics in medicine and surgery for in-patients, and for out-patients, including a genito-urinary clinic, a clinic for varicose veins, a L.C.C. Clinic for children suffering from rheumatic fever and chorea, and the X ray department for gastro-intestinal diagnosis. Particlars of post-graduate courses, which are held from time to time, can be obtained from the Secretary of the Hospital, Waterloo-road S.E., or from the Fellowship of Medicine.

Victoria Hospital for Children.

This hospital in Tite-street, Chelsea, S.W., contains 138 beds and a large out-patient department; the home at Broadstairs has 50 beds. Private wards in the Nurses' Home, named after H.R.H. Princess Mary (Viscountess of Harewood), at 29, Tite-street, adjacent to the hospital. Patients may be under the care of any medical practitioner holding an appointment on the staff of a recognised hospital, and the question of payment for his fees is arranged between him and the child's parents. Application for admission should be made to the Secretary.

Queen's Hospital for Children.

This hospital, for the sick children of the poor under 14 years of age, was formerly known as the North-Eastern Hospital for Children. There are 160 beds in London (Hackney-road, E.2) and 44 at the seaside branch, "Little Folks" Home, Bexhill. Special departments in Ear, Nose, Throat, Skin, and Eye, and Dentistry. Rheumatic Clinic in coöperation with L.C.C. schools weekly. A radiologist attends four times weekly. There are massage and light departments, and a special whooping-cough physician. The practice of the hospital is open to students by arrangement with the medical staff, and post-graduate instruction in children's diseases, lectures and demonstrations are given at times notified by the Fellowship of Medicine.

Paddington Green Children's Hospital.

This is a small hospital (42 beds) with a large out-patient department and a full staff, with Eye, Ear, Skin, Light, and Dental departments. The facilities which it offers for observation of clinical practice are used by the Fellowship of Medicine.

Hospital for Women.

This hospital in Soho-square, W., contains 82 beds. The teaching is available for post-graduates only in limited numbers. Operations take place on Tuesdays, Wednesdays, and Thursdays at 2 P.M. and on Mondays and Fridays at 9.30 A.M. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can also be gained in the treatment of malignant disease by means of radium. Incorporated is the London School of Gynæcology, comprising attendance in out-patient department, operating theatre, clinical lectures, and X ray treatment.

Samaritan Free Hospital for Women.

Contains 70 beds. Qualified practitioners are admitted as clinical (gynæcological) assistants to both the in- and out-patient departments. Full particulars may be obtained from the Secretary to the Medical Committee at the hospital, Marylebone-road, N.W.

East London Hospital for Children and Dispensary for Women.

There are 140 beds. Clinical instruction in Pediatrics is given to fifth-year Students at the hospital in Glamis-road, Shadwell, E. Two clinical clerkships for qualified or unqualified students are open every three months. Clinical assistants are from time to time appointed in the out-patient department. There is an Orthopædic Clinic on Wednesdays, and a

Rheumatism Clinic on Thursdays. Special instruction in Infant Feeding. Post-graduate Clinical Demonstration on the third Wednesday in each month.

Chelsea Hospital for Women.

This hospital, situated in Arthur-street, Chelsea, S.W., has 100 beds, and a certain number are reserved for patients paying £5 5*s.* a week and small fees to the surgeons for operations. There is a convalescent home of 32 beds at St. Leonards. At a large out-patient department the patients are seen at a nominal payment. The hospital caters for post-graduate teaching. In the out-patients' department clinical assistantships can be obtained which entitle the holder to attend out-patients and examine patients under the instruction of the visiting surgeons. The operating theatre is open to visitors, and all operations are demonstrated and discussed by the surgeons. Special intensive course, with lectures, special demonstrations, are held three times a year through the organisation of the Fellowship of Medicine.

Evelina Hospital and Belgrave Hospital.

The Evelina Hospital, Southwark (80 cots), and the Belgrave Hospital (76 cots), Clapham-road, also give facilities for out-patient practice.

OPHTHALMOLOGY.

Royal London Ophthalmic Hospital.

The attendance at Moorfields Eye Hospital (Moorfields, 1804–1899), City-road, E.C. (152 beds), is now very large. Operations are performed daily from 10 A.M. to 1 P.M., and four surgeons attend on each day. Students are admitted to the practice of the hospital, and special courses of instruction are given, which extend over a period of five months, by members of the Surgical Staff, beginning in October and March. The instruction and classes are arranged so as to meet the requirements for the various diplomas in Ophthalmology, both the preliminary examinations in Anatomy, Physiology and Optics, and those subjects required in the second part. Students of the hospital are eligible as house surgeons or clinical and junior assistants; these are appointed every three months.

Royal Westminster Ophthalmic Hospital.

This hospital, in Broad-street, Holborn, W.C. (85 beds, including 14 rooms for paying patients), has recently removed from its original site at Charing Cross to much larger premises, well adapted for teaching purposes. The clinics are held in the afternoons from 1 P.M. Operations are performed daily in the theatre at 3 P.M. Lectures and practical classes in the various branches of Ophthalmology, including Operative Surgery, Bacteriology, and Pathology, are held during the winter and summer sessions at 5 P.M. The practice of the hospital is open to both men and women practitioners, and medical students. Post-graduate students at the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant (seven appointments paid), and senior and junior assistants.

Royal Eye Hospital.

There are 44 beds and 2 cots at the hospital in St. George's-circus, Southwark, S.E. Clinical instruction is given to students and post-graduates daily at 2.30 P.M., and Lectures, Demonstrations, and Laboratory Classes are arranged in preparations for examinations in Ophthalmology. Apparatus has been installed for the Microscopy of the Living Eye. Post-graduate students are eligible for appointment as Clinical Assistants and as Refraction Officers. A new Clinic for paying patients under the Voluntary Hospitals Ophthalmic Clinic Scheme came into operation on July 1st.

Central London Ophthalmic Hospital.

This hospital, in Judd-street, St. Pancras, W.C., has 48 beds, and clinical teaching is given daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on other subjects, to meet the requirements of the Conjoint Board for the D.O.M.S., and of the University of London for the M.S. in Ophthalmology, are given during the winter months, commencing in October. This school is recognised as a teaching institution by the Universities of London and Oxford, as well as the English Conjoint Board. It receives a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. A clinical Demonstration is held by members of the staff at the Central London Ophthalmic Hospital at 5 P.M. on the first Tuesday of every month. Doctors and students of medicine are admitted free.

GENITO-URINARY AND VENEREAL DISEASES.

London Lock Hospital and Home.

In the institution at Harrow-road, W., founded 1746, there are 201 beds. In the male department and out-patient department in Dean-street, Soho, W., there are 37 beds. Male and female patients are seen at 91, Dean-street, Oxford-street, W.1, at any time from 9 A.M. until 9 P.M. daily, including Sundays. Intravenous injections are given at every clinic. Irrigations for males are given daily from 8 A.M. to 9 P.M. Female patients and children are seen daily at 283, Harrow-road, Paddington, W.9, from 9 A.M. until 8 P.M. Irrigations for females are given at any time. The hospital is linked up with the Fellowship of Medicine; special courses of lectures are held in May and November each year, and application for tickets should be made direct to the Secretary of the Fellowship. Only a limited number of practitioners and students are permitted to attend the practice of the Female Lock Hospital, and application should be made to the Dean at the Male Lock Hospital, between the hours of 11 A.M. and 5 P.M., or to the Secretary at the Head office, 283, Harrow-road, W. 9. Telephone No. 2272–3 Abercorn.

St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum.

At St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City-road, E.C. (founded 1835), for men and women, there are 62 general beds and 9 private beds. Operations are performed on Mondays, Tuesdays, Wednesdays, Thursdays, and Saturdays, 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Two weekly courses are held during the year in coöperation with the Fellowship of Medicine.

St. Peter's Hospital.

It is anticipated that a scheme for completely remodelling St. Peter's Hospital for Stone, &c., now in progress, will be completed by the end of 1931. There will then be avilable 33 male and 6 female beds. The new Department of Pathology with Museum (10, Henrietta-street, W.C.2) is open and in full work, and a completely up-to-date X ray department (diagnostic work only) is nearing completion. The alterations to the operating theatre and wards are well in hand, but during this period only an average of 20 beds are available for patients. Research is still carried out with Radium specially loaned for the purpose by the British Empire Cancer Campaign. Medical practitioners and students are invited to the clinical instructions, which are given in the out-patient department daily, excepting that the only out-patient clinic open to medical women is that held at 2 P.M. Fridays for women and children, and to the operations in the theatre on Mondays at 2.30 P.M., and Wednesdays and Fridays at 2 P.M. Post-graduate Courses of Lectures are given from time to time, dates being advertised in the medical journals.

All Saints' Hospital.

The in-patient department (31 beds) of the All Saints' Hospital for Genito-Urinary Diseases is at Finchley-road, and the terms of admission are free or by payment according to means. The out-patient department in the Vauxhall Bridge-road provides clinical instruction through the Fellowship of Medicine, in addition to which demonstrations in cystoscopy and other branches of genito-urinary work are available for all medical practitioners at the Out-patient department on Tuesday, Wednesday, Thursday, and Saturday afternoons, at 1.45 P.M., without fee

ORTHOPÆDICS.

Royal National Orthopædic Hospital.

This institution, situated in Great Portland-street, W. (480 beds), is a good example of the fusion of small and scattered activities for the creation of an effective whole. The three orthopædic hospitals of the metropolis were combined for the formation of this central institution at the instance of the King's Hospital Fund, with the result that the grants from this Fund and the income from subscriptions can now be used to far better purpose and with economy. The hospital has also been approved by the Ministry of Health for the treatment of tuberculosis, the connexion between orthopædics and the therapeutics required in many forms of tuberculosis having become obvious. Country branch at Brockley Hill, Stanmore (280 beds). Both branches of the hospital are residential schools for physically defective children, certified by the Board of Education. Post-graduate courses of 14 days each are held twice yearly.

EAR, NOSE, AND THROAT.

Central London Throat, Nose and Ear Hospital.

This hospital in Gray's Inn-road, W.C., is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinic. Lectures each Friday at 4 P.M. An intensive Course of Lectures (especially suitable to D.L.O. students), with Anatomy and Physiology Class, Operative Surgery Class, Peroral Endoscopy Class, and Pathology Class is given twice yearly—in May and October. Preparatory courses in methods of Examination and Diagnosis at frequent intervals. Consultations on interesting cases take place on the fourth Wednesday in each month at 4 P.M. Clinical Assistants are appointed and are expected to hold office for at least three months. They are required to attend twice weekly at 1.30 o'clock for the afternoon, and at 4.30 o'clock for the evening clinics. New wing, with complete out-patient department and additional wards, was opened in August, 1929.

Golden-square Throat, Nose and Ear Hospital.

The hospital has absorbed the London Throat Hospital, formerly of Great Portland-street. The hospital is situated in Golden-square, near Piccadilly-circus. Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 P.M., and on Tuesdays and Fridays from 6.30 to 9 P.M. There is an annual out-patient attendance of over 65,000. Minor operations are performed on Mondays, Wednesdays, and Fridays at 9.30 A.M. The hospital now contains 101 beds, of which 25 are for private patients. Practitioners and medical students are admitted to the practice of the hospital, and clinical assistants are appointed periodically.

Metropolitan Ear, Nose, and Throat Hospital.

The hospital (founded 1838) is in Fitzroy-square, W. The Out-patient Department is opened daily at 2.30 P.M., Saturdays 1.30 P.M., to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, Thursdays, and Fridays at 10 A.M. Clinical Assistants are appointed as vacancies occur.

SKIN.

London School of Dermatology.

The London School of Dermatology, St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C., has an in-patient Department (33 beds) at 262 Uxbridge-road, W., and out-patient Clinics are held daily at 2 and 6 P.M. (Saturdays 2 P.M. only), when demonstrations are given on the cases presenting themselves. The Chesterfield Lectures, constituting a systematic course in dermatology, are given on Tuesdays and Thursdays at 5 P.M., from October to March, by the hon. medical staff of St. John's Hospital and the physicians in charge of the Dermatological Departments of the London Teaching Hospitals. The lectures are free to those attending the practice of the hospital and to registered medical students. At the end of the course an examination is held for the Chesterfield Medal in Dermatology, and is open to all medical practitioners, the examination fee being £2 2*s*. The electrical department is open daily from 2 to 4 P.M., except on Wednesdays and Saturdays. Laboratory Courses in the Pathology and Bacteriology of the Skin can be arranged.

London Skin Hospital and Hospital for Diseases of the Skin.

The London Skin Hospital (Fitzroy-square) and the Hospital for Diseases of the Skin (Blackfriars-road) admit graduates to their practice, which is among out-patients. London Skin Hospital, daily at 2 P.M. and 5.30 P.M.; Hospital for Diseases of the Skin, daily at 2 p.m., and Fridays, 5.30 P.M.

CENTRES OUTSIDE LONDON AFFORDING EDUCATIONAL FACILITIES.

Nearly every hospital of a general character in the country having more than 150 beds falls within this category, and certain of them have already been noticed in connexion with the universities to which their clinical practice is attached. The hospitals vary much in size and scope.

The following alphabetical list includes the provincial hospitals which are recognised by the English Conjoint Board for a part of the required training in medical and surgical practice through clerkships and dresserships.

Bath Royal United Hospital.

This hospital contains 212 beds, 72 of which are situated in Combe Park, Bath, and are for paying patients only, and possesses X ray, Massage, Bacteriological Departments, a Pathological Laboratory, and a fine library. Secretary-Superintendent: Mr. J. Lawrence Mears. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men), at 5 P.M., and Ear, Throat, and Nose Clinics on Wednesdays, at 1.45 P.M.

Bedford County Hospital.

This hospital at Bedford has 124 beds, including 15 beds in the paying and 13 beds in the maternity wards; Ear, Nose and Throat Departments, and X ray and Pathological Departments. There is in connexion with the institution a convalescent home (20 beds) at Aspley Heath, near Woburn Sands. The hospital is approved by the University of London for the M.D. and M.S. Examinations. Secretary: Mr. B. Wadmore.

Bradford Royal Infirmary.

This hospital at Bradford contains 215 beds and, in addition, has 50 recovery beds at the Woodlands Convalescent Home, Rawdon. The acting staff consists of 4 Honorary Physicians, 4 Honorary Surgeons, 1 Honorary Radiologist, 1 Honorary Laryngologist, 1 Honorary Ophthalmic Surgeon, 1 Honorary Dental Surgeon, 1 Honorary Assistant Dental Surgeon, 2 Honorary Assistant Physicians, 2 Honorary Assistant Surgeons, 6 Anæsthetists, 1 Pathologist, 1 Physician-in-charge of Radium Therapy Department, 1 Resident Surgical Officer, 1 House Physician, and 4 House Surgeons. There are special clinics for Orthopædic cases, for Electrotherapeutic and Sunlight Treatment, and for Radium Therapy. A new hospital of 360 beds is in construction, and a self-contained block for 70 paying patients has been opened adjoining the new Infirmary. Secretary-Superintendent: Mr. J. J. Barron.

Coventry and Warwickshire Hospital.

There are 307 beds available at the Main Hospital at Coventry (established 1840), and 40 beds at the Alcock Convalescent Hospital, Keresley (three and a half miles distance), which is used as an annexe. At the Main Hospital there are separate Medical, Surgical, Maternity, Children's and Accident Wards, also separate Ophthalmic Block complete with its own Theatre. There are separate departments for Clinics for Ear, Nose and Throat Diseases, X Ray, Electrical, and Sunlight Clinics, also V.D. Clinic. There is also an up-to-date Pathological Laboratory.

Derbyshire Royal Infirmary.

This general hospital at Derby (347 beds) was rebuilt in 1892–94. In recent years there have been numerous alterations and additions to keep pace with modern requirements. The hospital is built on the pavilion system and provides, in addition to the usual Medical and Surgical blocks, a separate Ophthalmic block of 40 beds, a separate Children's block of 34 beds (Medical and Surgical). Gynæcological Wards, and an Ear, Throat, and Nose Department. There is a large and well-equipped Out-patient Department, also separate Orthopædic, X Ray, Electrical, Pathological, and Venereal Diseases Departments. The salaried Medical Staff consists of a non-resident Staff of 1 Surgeon-in-charge of X Ray and Electrical Departments, 1 Surgeon-in-charge of Venereal Diseases Department, 4 Anæsthetists. and a Resident Staff of 4 House Surgeons, 1 House Physician, and 1 Assistant House Surgeon and Casualty Officer. Registered Medical Students are admitted to witness the medical and surgical practice on payment of fees. Superintendent and Secretary: Mr. Walter Banks, F.C.I.S.

Gloucestershire Royal Infirmary and Eye Institution.

This hospital at Gloucester has 155 beds. Secretary: F. J. Symons. An Electrical and Massage department has been established and Venereal Clinic opened. Also Ear, Nose, and Throat department, X Ray department, Ultra-violet Ray department, Orthopædic department, Dental department, and Pathological Laboratory.

Hull Royal Infirmary.

This hospital at Hull contains 270 beds, plus 100 beds at the branch hospital at Sutton-on-Hull, opened in February last. Since the establishment of the Parent Institution in 1782 it has undergone steady additions and improvements, including up-to-date Ophthalmic, Radiological, Nose, Throat and Ear, Dental, V.D., Violet Rays, and Pathological Departments. A Clinic for Functional Nervous Diseases has recently been opened in conjunction with the Hull Corporation, under the Mental Treatment Act, 1930. Recent extensions include a new Operating Theatre, Nurses' Home, and extensions to the old X Ray, Electrical, and Out-patient Departments. The Resident Staff consists of 1 House Physician, 1 House Surgeon, 1 Assistant House Physician, 2 Assistant House Surgeons, 1 Assistant Surgeon to Special Departments, 1 Casualty Officer. Sutton Branch: 1 House Surgeon and 1 House Physician. An annexe at Withernsea has accommodation for 30 patients. The senior house physician's appointment is recognised by the University of London for the M.D., Branch I. (General Medicine) examination. It also recognises the posts of senior house surgeon and second house surgeon for the M.S., Branch I. (General Surgery) examination. The post of house surgeon to the Special Departments is recognised by the Conjoint Board of the Royal Colleges for the examinations for the Diplomas in Ophthalmic Medicine and Surgery, and Laryngology and Otology. The hospital is also recognised by the Royal Colleges for the F.R.C.S. examinations.

Kent and Canterbury General Hospital.

The hospital at Canterbury contains 120 beds. Pupils of the staff are admitted to the practice of the hospital. Operations daily. Special departments include Ophthalmic, Ear, Nose and Throat, Venereal, Orthopædic, Electrical, Actinotherapeutic, X Ray, and Bacteriological. The hospital is recognised by the University of London for the purpose of the M.D. and M.S. examinations. Superintendent and Secretary: Mr. W. T. Southwood.

Leicester Royal Infirmary.

At the General Infirmary, Leicester, there are 392 beds (children's 66, and venereal diseases 15). In addition 63 beds have been retained at local convalescent homes for the reception of early recovery cases, and £330,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of four modern operating theatres, three new wings, and self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Pathological laboratories and post-mortem rooms were erected at a cost of £11,000, also an orthopædic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home has recently undergone enlargement by 60 bedrooms, and now provides for 150 nurses and staff. A large house has been purchased to accommodate the night nurses, but it is hoped to provide additional accommodation to enable all the nurses to be accommodated in one home. For this purpose the nurses' home is to be enlarged at a cost of £50,000. Other recent structural improvements comprise reconstruction of the kitchens, new temporary ward of 30 beds, and a new venereal disease department. There are twelve resident salaried medical officers—viz., four house surgeons, one casualty officer, two house physicians, three anæsthetists, and two dressers. Most of the posts are filled half-yearly, April and October, and afford exceptional opportunities for post-graduate experience and senior students. Dressers are given an honorarium. Students who seek resident dresserships should apply to the House Governor and Secretary. A post-graduate course of lectures is arranged annually by the Leicester Medical Association, and also clinical classes are held for graduates preparing for M.D. and M.R.C.P.

Norfolk and Norwich Hospital.

This hospital at Norwich has at present 392 beds. There is a convalescent home with accommodation for 35 patients at Cromer. The Resident Medical Staff consists of one House Physician, three House Surgeons, one House Surgeon to the Ear, Nose, Throat, and Eye Department, and one Casualty Officer. There is also a Private Patients' Home which has at present 20 beds. Students are admitted to the practice of the hospital for a fee of £5 5s. for six months. House Governor and Secretary: Mr. Frank Inch.

Northampton General Hospital.

Two new wings of this hospital at Northampton were opened in 1901, and the old buildings entirely renovated and rearranged. In 1926 a new isolation block of 30 beds was opened. The number of beds is 246. There is an up-to-date Pathological Laboratory, also X Ray and Therapeutic Department and V.D. Clinic. Two new operating theatres have been built, and a new ophthalmic in-patient department has recently been completed.

North Staffordshire Royal Infirmary.

The New Infirmary, opened in 1869, at Hartshill, Stoke-on-Trent, is built on the pavilion plan, has accommodation for about 346 patients, including Children's wards, a Bacteriological and Pathological department, and a department for the treatment of Diseases of the Eye, X Ray and Electrical department (including Ultra-Violet Ray Lamps); Cardiographic department, a department for the treatment of Diseases of the Ear, Nose, and Throat, an Orthopædic department, an Electrocardiograph department, Dental department, and Venereal Diseases clinics, including daily Intermediate Treatments. Recent extensions comprise a new ward block, new X Ray and Orthopædic departments with connecting corridors to the existing infirmary, large extensions to the nurses' home, a new boiler house, new chimney stack, and a new laundry. Secretary and House Governor: Mr. W. Stevenson.

Nottingham General Hospital.

There are at this hospital 377 beds available for medical and surgical patients, and 54 beds are in the detached branch, known as "The Cedars" Branch of the General Hospital. The Resident Medical Staff consists of 2 House Physicians, 4 House Surgeons, 1 Aural House Surgeon, and 2 Casualty Officers. The special departments are the Ear, Nose and Throat, Skin, Dental, Massage, X Ray, Orthopædic, Electro-therapeutic, Ultra-Violet Light. House Governor and Secretary: Mr. P. M. MacColl.

Royal Berkshire Hospital.

This hospital at Reading, which contains 268 beds, includes an Out-patient Department, a Casualty Department, an X Ray and Radiotherapeutic Department, Electrotherapeutic and Massage Department, an Orthopædic Department, a V.D. Clinic, a Laboratory, an Eye Theatre, Eye Wards, a Maternity Ward, a Paying Patients Unit, and a Private Nursing Staff, and two motor ambulances. The hospital is approved as a Training School for Nurses and by the Ministry of Health for V.D. Treatment. The Blagrave Branch, Calcot, opened in 1930, contains 63 beds for cases of disease of bones and joints and those requiring open-air treatment.

Royal Devon and Exeter Hospital.

The hospital at Exeter contains 225 beds (including special children's wards) and has a good library, museum-post-mortem room, and pathological laboratory. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897 and the "Victory" wing for the treatment of discharged disabled soldiers and sailors completed and opened in 1922. Doctors in practice may use the museum and library. The Electrical Treatment Department, opened in 1907, was enlarged in 1925, and now forms one of the most important sections of the hospital. At the department for the treatment of genito-urinary diseases there are three sessions per week, two for men at 3 P.M. and 7 P.M., and one for women at 3 P.M.

Royal Hants County Hospital.

The hospital at Winchester contains 168 civilian beds. Secretary: Mr. Herbert Maslen.

Royal Hospital, Portsmouth.

The hospital contains 195 beds. There are Pathological, X Ray, Massage, and Medical and Surgical Out-patient departments.

Royal Hospital, Wolverhampton.

There are 240 beds. Special Departments for Children, Infectious Cases, Gynæcology, Maternity, Ear, Throat, and Nose Diseases, Electrotherapeutic and X Rays, Orthopædics, Artificial Sunlight, Venereal Disease, Pathological and Biochemical Laboratories, Dentistry, Radium, and Electrocardiograph. There is an excellent medical library. The Resident Staff consists of Resident Assistant Surgeon and Surgical Registrar, one House Physician and five House Surgeons. Women's Department, one Resident Medical Officer, and one House Surgeon. Pupils are allowed to witness the whole of the practice of the hospital, and to be present at operations, and have every opportunity of acquiring a practical knowledge of their profession. The hospital is recognised by the various Examining Bodies for a part of the requisite attendance on Medical and Surgical Practice. A course of Practical Pharmacy is given by the Pharmacist. Fees on application. Applications should be made to the Honorary Secretary of the Medical Committee.

Royal Salop Infirmary.

This hospital at Shrewsbury has 150 beds. In-patients, 1992; out-patients, 1402; out-patients' attendances, 32,638; accidents and casualties, 6225; dental cases, 519. Secretary-Superintendent: J. W. Noble. The New Wing for the reception of Women and Children is capable of accommodating some 40 patients.

Royal South Hants and Southampton Hospital.

This hospital at Southampton contains 250 beds with every facility for clinical instruction. Special Departments: Ear, Nose, and Throat, Ophthalmic, Dermatological, Electro-Cardiograph, X Ray, Massage and Electricity, Ultra-Violet Ray, Venereal Diseases. Large Out-patient Department.

Royal Sussex County Hospital.

This hospital at Brighton has 246 beds and affords ample facilities for students, possessing a large out-patient department, including Ophthalmic, Dental, Dermatological, Ear, Nose and Throat, X Ray, and Electrotherapeutic sections, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years, on payment in advance of a fee, not exceeding 20 guineas, as the Board of Management shall direct.

Salisbury General Infirmary.

This hospital at Salisbury contains 161 beds. Maternity and antenatal ophthalmic wards; and Ear, Nose and Throat Wards; maternity and child welfare clinic.

South Devon and East Cornwall Hospital.

This hospital at Plymouth has 240 beds (including 10 for venereal diseases in a separate building). Special departments include Pathological, X Ray, Deep Therapy, Cardiographic, Ultra-Violet Rays, Electrotherapeutic, Orthopædic, Gynæcological and Aural; also medical and surgical out-patients. Pensioners are received as in-patients, and are also treated as out-patients.

Staffordshire General Infirmary.

This hospital was established at Stafford in 1766, and has over 100 beds. It is a Training School for Nurses. Paying Patients are accepted. Mr. A. E. Collins, Secretary.

West of England Eye Infirmary.

Students of the Exeter hospital can attend the practice of the Eye Infirmary (64 beds). A ward is set aside for newly-born babies suffering from infectious eye diseases. Mothers with babies are accommodated.

Worcester General Infirmary.

This hospital at Worcester has 132 beds. Pupils are taken by members of the Honorary Medical and Surgical Staff. New X Ray and Electrical and Wolfram Arc Light, Ear, Nose and Throat, and Orthopædic Departments have been erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII., and fire-escape staircases erected. Plans have been prepared for an increase in bed accommodation to 200 beds; also Pathological Laboratory and two new Operating Theatres. A Gynæcological Department has recently been instituted, and a new nurses' home is being built. There is a Department for Venereal Diseases and Surgical Tuberculosis cases are treated. There is also a Mental Outpatient Clinic.

York County Hospital.

This hospital at York contains 190 beds. There are balconies for outdoor treatment, X Ray department, electrotherapeutic and massage department, actinotherapy installation, clinical laboratory, and a Zünd-Burguet apparatus for treatment of chronic deafness. There are clinics for Functional Nervous Disorders, Venereal Diseases, and Electrocardiography.

MEDICAL EXAMINING BODIES AND SCHOOLS IN SCOTLAND.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., *M.B.*, *Ch.B.*, *M.D.*, and *Ch.M.* The degree of *Ch.B.* shall not be conferred on any person who does not at the same time obtain the degree of *M.B.*, and the degree of *M.B.* shall not be conferred on any person who does not at the same time obtain the degree of *Ch.B.* No one is admitted to the degrees who has not been engaged in study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course in Clinical and Practical Midwifery and have personally conducted 12 cases.

With respect to the places and institutions at which the studies of the candidates may be prosecuted the following regulations have effect:—Three of the five years of medical study must be spent in the University of Edinburgh. The remaining two years may be spent in any University of the United Kingdom, or in any Indian, Colonial or Foreign University or medical school recognised for the purpose by the University Court. Women are admitted to graduation in medicine under the same conditions as men.

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted.

Post-graduate Instruction.—The University takes part in the Courses given under the auspices of the Edinburgh Post-graduate Courses in Medicine. In the departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for approved candidates for the Degree of Ph.D.

In connexion with the University and Royal Colleges Post-graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-graduate Courses in Medicine.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars concerning these, as well as concerning the fees at different stages, can be obtained from the Dean of the Medical Faculty.

Edinburgh Royal Infirmary.

At this institution there are 1011 beds, including 42 cots for children. The clinical work of the Edinburgh student is done at the Royal Infirmary. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There is also a large and complete Radiological Department in which is given theoretical and practical instruction for the University Diploma in Radiology, &c. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology.

The appointments are: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department.

Facilities are given in connexion with the Post-graduate Courses arranged by the Edinburgh University and the two Royal Colleges jointly.

Royal Hospital for Sick Children.

The hospital at Sciennes-road, Edinburgh, has 132 beds, fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given thrice throughout the year by the staff. Each course consists of 50 meetings and combines medicine and surgery. Post-graduate Courses of Lectures are held during the summer vacation. Full particulars with regard to teaching can be obtained from the Dean's Office, University New Buildings, Edinburgh.

Edinburgh Eye, Ear, and Throat Infirmary.

Clinical Lectures and Instruction are given in this institution (with which is incorporated the Edinburgh Eye Dispensary) at 6, Cambridge-street, Lothian-road, open at 1 o'clock daily for out-door patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for out-door Ear, Nose, and Throat Patients. Patients whose diseases require operations or extra care are accommodated in the house (10 beds). Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time. A Post-graduate Course in Diseases of the Ear, Nose, and Throat is held each academic term, commencing in May, October and January, and continuing for six weeks. The next course commences in October. The class meets at 5 P.M. on Tuesdays and Fridays, and the instruction, which is practical, is supplemented by lantern demonstrations. Full particulars from the Secretary, 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university.

and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: *M.B.* and *Ch.B.* (always conjointly), *M.D.* and *Ch.M.*; *B.Sc.* in Public Health; *D.Sc.* in Public Health; *B.Sc.* in Pharmacy; and *Ph.D.* in the Faculty of Medicine. A Diploma in Public Health (*D.P.H.*) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must attend a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), with Practical Chemistry, three terms; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine with nine months more of general hospital practice; the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects: Ophthalmology, Diseases of the Ear, Throat and Nose, Venereal Diseases, Tuberculosis, Fevers, Vaccination. The final year consists of three intensive terms of study: one devoted to Midwifery and Diseases of Women, one to Surgery, and one to Medicine.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases Peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are granted to candidates, not under 24 years of age, who have previously obtained the double bachelorship, on completing examinations in Clinical Medicine for M.D., and in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M. The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College, and must prosecute a course of special study or research for two or three years and give evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject matter of the thesis.

Post-graduate Medical Teaching is available under the auspices of Glasgow Post-Graduate Medical Association, which is representative of practically all the Teaching Institutions in Glasgow. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. There is a General Medical and Surgical Course during the last two weeks of August and the first two weeks of September. This is a whole-time course and includes most of the subjects of interest to the general practitioner. The forenoons are occupied with General Medicine and Surgical Diagnosis and Minor Surgery in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in some of the special hospitals or in the special departments of the general hospitals—two subjects each afternoon. On the four Saturday forenoons Tuberculosis and Infectious Fevers are demonstrated at Ruchill Fever Hospital. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out detailed investigations as directed. Further information may be obtained from the Secretary of the Association, 9, Woodside-terrace, Glasgow.

There are many Bursaries, Scholarships, and Prizes in connexion with the Medical Course.

Glasgow Royal Infirmary.

The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. New Lectureships in Materia Medica and Pathological Biochemistry were established recently, and a lectureship in Bacteriology has been founded. St. Mungo's College, which embraces and continues the original Royal Infirmary Medical School, is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, over 800 beds. In addition to the large medical and surgical departments, there are special wards for diseases of women, of the throat, nose, and ear, skin, eye, burns, septic cases, biochemical investigation, and urology. The wards are open to Women Students. Six house physicians and nine house surgeons, who board in the hospital free of charge, are appointed every six months; also five non-resident house physicians, nine non-resident house surgeons, and one non-resident dental house surgeon. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a various character are received, these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion and Massage Department, and School of Massage, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Classes are held during August and September in Clinical Medicine, Clinical Surgery, Clinical Gynæcology, Diseases of the Skin, Biochemistry, Diseases of the Throat, Nose and Ear, and in Diseases of the Eye. Tutorial Classes for senior students are also held in August and September.

For information regarding fees and other particulars, application should be made to the Superintendent.

Glasgow Western Infirmary.

This hospital of 642 beds adjoins the University. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Nose, Teeth, Skin, Venereal Disease, and Electro-therapeutics. Radium centre for Glasgow and the West of Scotland. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological and Bacteriological Departments the courses are both systematic and practical, and extend through the winter and following summer; these are likewise recognised by the University for graduation. In addition Post-Graduate Courses are held. Eighteen resident assistants are appointed annually from those who have completed their course. In the Clinical Laboratory students receive laboratory instruction from the lecturer on clinical methods. A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics. Secretary: J. Matheson Johnston, C.A.

Victoria Infirmary.

This institution, situated at Langside, and having its office at 67, Carlton-place, Glasgow, has 427 beds, and is the third of the extensive general hospitals in Glasgow to afford opportunity for clinical instruction to students. In addition to a full general staff there is a clinical research laboratory with pathologists and bacteriologists attached; radiological instructor, and a full assortment of specialists. The Bellahouston Dispensary, also with a clinical staff, is conducted in connexion with the Victoria Infirmary. For further particulars of the clinical practice application should be made to the Medical Superintendent.

Anderson College of Medicine.

Courses are given at Dumbarton-road, Glasgow, W., which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students. Women students are admitted on the same terms as men, and the Carnegie Trust extends its benefactions to students of the College. (Full particulars may be obtained from the Carnegie Trust Offices, Merchants' Hall, Edinburgh.)

Candidates for the L.D.S. can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Dental Hospital, Glasgow.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty. Communications relating to the Preliminary Examination in General Education to be addressed to the Educational Institute Office, 47, Moray-place, Edinburgh; and relating to the Triple Qualification and to the Dental Qualification to be addressed to Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

Queen Margaret College.

Queen Margaret College (Women's Department of the University) is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curricula, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. The school of medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. The women students attend classes in the various University Buildings at Gilmorehill and Queen Margaret College, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Facilities for clinical work are given in the Royal, Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine, and women are admitted to certain University bursaries and fellowships.

St. Mungo's College and Glasgow Royal Infirmary.

The classes in St. Mungo's College qualify for the medical qualifications of the English, Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. Further particulars can be obtained from the Secretary of the Medical Faculty.

Royal Hospital for Sick Children, Glasgow.

This institution consists of: (1) a hospital at Yorkhill containing 275 cots, built on an elevated and central site close to the University; (2) a Dispensary, or Out-patient Department, in West Graham-street; and (3) a Country Branch at Drumchapel, Dumbartonshire, containing 80 cots. Children treated must not be over 13 years of age, nor suffer from infectious diseases. In 1930 there were 5247 patients treated in the wards, and the number of attendances of out-patients was 89,103. There are one professorship and four lectureships in the University of Glasgow in connexion with the hospital, one professorship and one lectureship on the Medical Diseases of Infancy and Childhood, one lectureship on Surgery and Orthopædics in relation to Infancy and Childhood, one lectureship on Biochemistry in relation to Infancy and Childhood, and one research lectureship on the Pathology of the Diseases of Infancy and Childhood. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition, special facilities are given for post-graduate study. Resident House Physicians and Surgeons are appointed every six months, in April and October. Full information may be obtained from the Medical Superintendent.

Glasgow Royal Maternity and Women's Hospital.

The average daily number of patients in the hospital at Rottenrow is 140, and of the 4000 cases admitted to the wards per annum, over 60 per cent. are classified as abnormal. There are also about 3500 mothers attended per annum in their own homes. The work of the antenatal wards with their 40 beds is supplemented by large antenatal clinics where over 4000 new patients are seen in the course of the year. Splendidly equipped Research Laboratories were opened in 1926. The Visiting Staff of the hospital includes a Pædiatrician, who gives daily attendance. The practice of the hospital affords a wonderful field for post-graduate study and experience. Inquiries should be addressed to the House Superintendent.

Glasgow Royal Samaritan Hospital for Women.

Increased to 160 beds by building extensions completed in 1927, the hospital offers excellent facilities for clinical instruction in the diseases peculiar to women. Lectures and clinical demonstrations are given by members of the surgical staff to students and to post-graduates; and the hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for coördinating post-graduate medical teaching in all the hospitals. The Royal Samaritan Lectureship in Gynæcology is a University Lectureship associated with the hospital.

For further information, application may be made at the hospital, or to the Secretary, 200, St. Vincent-street, Glasgow.

Glasgow Lock Hospital.

The hospital at 41, Rottenrow, Glasgow, contains 84 beds for the treatment of females suffering from Venereal Diseases. There is also a Labour Ward, and a [illegible] d [illegible]ensary for out-patient attendances. There is a Lecture Room and a Laboratory, equipped with modern appliances, where University classes on the subject are dealt with. Post-graduate classes are also held. Recently the hospital has been completely renovated and modernised. Full information from the Secretary and Treasurer, Mr. J. Neilson Gray, LL.B., 65, Bath-street, Glasgow.

Glasgow Ophthalmic Institution.

This institution, at 126, West Regent-street, and 131, Wellington-street (30 beds and six cots), is administered by the Royal Infirmary. Clinical and systematic courses of lectures for students during the winter and summer sessions. Operations on Wednesdays and Fridays. Post-graduate classes and demonstrations are arranged during the summer. For information regarding fees and other particulars application should be made to the Superintendent, Royal Infirmary.

Glasgow Eye Infirmary.

The wards and dispensary at Berkeley-street and Charlotte-street are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine, and by the Royal Colleges of Physicians and Surgeons of England for the Diploma in Ophthalmic Medicine and Surgery. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Post-graduate Classes are held. Secretary and Acting Treasurer, Mr. William M. Moore, 171, West Regent-street, Glasgow.

Glasgow Ear, Nose and Throat Hospital.

The hospital contains 54 beds. At out-patient and indoor departments at 306, St. Vincent-street, clinical instruction is given. A Research Department has been installed. Post-graduate Courses are held during the year. Secretary: D. N. Mackay, 38, Bath-street, Glasgow, C.2.

UNIVERSITY OF ST. ANDREWS.

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews (United College, St. Andrews and University College, Dundee)—viz., *M.B.*, *Ch.B.*, *M.D.*, *Ch.M.*, a Diploma in Public Health, Diploma in Dental Surgery (*L.D.S.*), and a Diploma in Public Dentistry.

The extent and standard of the Preliminary Examination is determined by the Scottish Universities Entrance Board, constituted under Ordinance No. 70 of the Scottish University Courts (General No. 3—Regulations as to Admission to the Scottish Universities for purposes of graduation), in accordance with the terms of that Ordinance. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities exempts. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, *including such examinations as may be prescribed in the various classes*—viz., Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, Practice of Medicine, Surgery, Midwifery, and the Diseases peculiar to Women and Infants, Pathology, Bacteriology, Practical Chemistry, Physics, Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere with not fewer than 80 patients, with a distinct staff of physicians and surgeons, and recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology, Venereal Diseases, Tuberculosis, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica, Pathology and Bacteriology, Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

University College, Dundee.

The Medical School in St. Andrews University is carried on as follows. Part or whole of the medical curriculum of St. Andrews University must be taken here. Provision is made by St. Andrews University for instruction in the work of the first two years, including Anatomy and Physiology, in both St. Andrews and Dundee. The last three years of the curriculum must be taken in Dundee in University College, which is a constituent part of St. Andrews University.

Dundee Royal Infirmary.

In addition to the ordinary Medical and Surgical Wards (461 beds), there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose, and Throat, and of the Skin; and for Clinical Pathology, Radiology, Electrotherapeusis, and Electrocardiography. A new Maternity Department, built at a cost of £37,000, has recently been opened. The Pathological Department is being reconstructed. Clinical teaching is given to male and female students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the other Universities and Boards of the United Kingdom. Ten Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the Physicians and Surgeons; and Students are appointed as assistants in the pathological department. Further information may be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., *M.D.*, *Ch.M.*, *M.B.*, and *Ch.B.* The Degree of Doctor of Philosophy (*Ph.D.*) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Candidates, before entering on the curriculum, must have passed the Preliminary Examination or hold a qualification recognised as exempting from such examination.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Biology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Forensic Medicine, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital, they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, Radiology, X Ray, Therapeutics and Electrical Treatment, and Clinical Chemistry, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis (in duplicate) has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis (in duplicate) must be presented for approval.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 24 Bursaries (competition and presentation) are open each year, of £10 to £45 per annum in value, most of them being tenable for three years. Scholarships: five Post-graduate Scholarships, ranging in value up to £250 per annum. Prizes and Medals: 15 Gold Medals and Prizes for proficiency in special departments.

Aberdeen Royal Infirmary.

There are 366 beds. The main clinical work of the students is done in the infirmary with its general and special facilities, including a Department of Clinical Chemistry.

Aberdeen Royal Mental Hospital.

This hospital contains about 900 beds. The class of Mental Diseases meets at the University of Aberdeen, and clinical instruction is given at the hospital during three months in summer. Physician-Superintendent, Dr. R. Dods Brown.

Other Hospitals.

Students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, Lying-in and Vaccine Institutions, and the Ophthalmic Institution.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

CONJOINT EXAMINING BOARD.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three bodies. This is the Scottish Conjoint Board. The three bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery.

The hospitals which are recognised by the Scottish Conjoint Board as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities, as well as all the places which are recognised by the English and Irish Conjoint Boards.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, 2 terms; Elementary Inorganic and Organic Chemistry, 2 terms; Anatomy, Practical Anatomy, 5 terms; Theoretical including Biochemistry and Biophysics, 5 terms; Physiology, Materia Medica, 2 terms; Pathology (including Practical Pathology), 3 terms; Practice of Medicine, 2 terms; Clinical Medicine, 3 terms; Principles and Practice of Surgery, 2 terms; Clinical Surgery, 3 terms; Midwifery and Gynæcology, 2 terms; Diseases of Children, one term; Medical Jurisprudence, one term; and Public Health, one term. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months' instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than nine months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for three months the practice of a public dispensary especially recognised by any of the above authorities, and three months' attendance at the out-patient department of a recognised general hospital. This attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following three-monthly courses: Diseases and Injuries of the Eye; Insanity; Infectious Diseases; Gynæcology; Diseases of Children. The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Systematic and Practical Biology, Chemistry and Physics.

The *Second Examination* must be Written, Practical, and Oral, and consist of the following subjects:—(1) Anatomy and Embryology, and (2) Physiology, including Histology (if not included in Anatomy).

Biochemistry, and Biophysics. Candidates may be admitted to this Examination on production of the necessary certificates of curriculum.

The *Third Examination* must be Written, Practical and Oral, and consist of the following subjects:—(1) Pathology, including Bacteriology and Morbid Anatomy, and (2) Pharmacology (Theoretical and Practical), including Pharmacological Chemistry, the Principles of Therapeutics, and Prescription Writing. Candidates may be admitted to this Examination on production of the necessary certificates of curriculum.

The *Final Examination* must consist of the following subjects[1]:—(1) Medicine, including Therapeutics, Applied Anatomy and Physiology, and Clinical Pathology with Practical Medicine; (2) Surgery, including Applied Anatomy and Physiology, Clinical Pathology, with Practical Surgery; (3) Midwifery and Diseases of Women, Clinical Obstetrics and Gynæcology, with Practical Midwifery; and (4) Medical Jurisprudence and Public Health. Medicine, Surgery, and Midwifery must be taken together, and Medical Jurisprudence and Public Health, and not earlier than on the conclusion of five Winters and five Summers of Medical Study, provided that a period of 36 months has elapsed since passing the Second Professional Examination. The Schedule for the Final Examination must contain a summary of the entire Course of Study, and, properly attested or proved by Certificates, must be lodged with the Inspector, and the fee paid, not later than one week before the examination. At the same time there must be produced a Certificate to show that the Candidate is not less than 21 years of age. No Candidate can be exempted from examination on any subject of the Final Examination (with the exception of Medical Jurisprudence and Public Health) unless he has already passed in the subject at this Board.

In addition to the Written and Oral Examinations all Candidates must be subjected to Clinical Examinations in Medicine, Surgery, and Midwifery and Gynæcology, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope and of other instruments, Clinical Chemistry, Surgical Appliances, Bandaging, Surface markings, Skiagrams, &c. The Oral Examination include the recognition of specimens. All Candidates for the Final Examination must complete the three portions (Medicine, Surgery, and Midwifery) within a period of 19 months.

There are four periods of examination annually.

The Registrar in Edinburgh is Mr. David Thomson, 49, George-square; and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom particulars of fees can be obtained.

School of Medicine of the Royal Colleges, Edinburgh.

The Lectures in this School qualify for graduation at Edinburgh and other Universities, for the Examinations of the Conjoint Boards of Edinburgh and Glasgow, London, and Dublin. The number of students attending varies from year to year, and for the past few years the average number has been about 600. In accordance with the Statutes of the University of Edinburgh one half of the qualifying classes required for graduation there may be attended in this School, the fees paid for such classes being the same as those for the corresponding University classes. Special classes of instruction for Dental students are included in the curriculum. Post-graduate courses are conducted in conjunction with the University. Further particulars regarding the School, also its calendar (price 8*d*., including postage), may be had on application to the Dean of the School, Surgeons Hall, Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

In addition to the Diplomas granted by the Scottish Conjoint Board, the Royal College of Physicians grants its Single Licence to candidates whose names are already on the Medical Register.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence.

Fellowship.—The Fellows are selected from the ranks of the *Members*.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College of Surgeons of Edinburgh admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The College grants a diploma of Fellowship after examination to the holders of British surgical degrees or diplomas and the holders of recognised degrees of the Universities of Canada, Australia, and New Zealand.

The Fellowship.—Candidates must be 25 years of age and in practice for at least two years. The examination is written and viva voce, and includes surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. Candidates are not allowed to appear for more than three times at the examinations. One month's notice of intention to appear for examination must be given by the candidate to the College.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held separately. The Licence is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology, or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate to the Faculty. In certain circumstances Fellows may be elected as a mark of distinction. Registrar: Mr. Walter Hurst, 282, St. Vincent-street, Glasgow.

---

[1] Candidates at the Final Examination may be examined on Diseases of Children, Fevers, Tuberculosis, Insanity, Skin Diseases, Diseases and Injuries of the Eye, Diseases of the Ear, Throat, and Nose, Radiology, Venereal Diseases, Orthopædics, Vaccination, and Anæsthetics.

MEDICAL EXAMINING BODIES AND SCHOOLS IN IRELAND.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March, and in July. Courses in preparation for it may be taken in the School of Physic.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Botany, Zoology, Physics and Chemistry; Descriptive and Applied Anatomy; Histology, Physiology and Applied Physiology; Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Practice of Medicine; Surgery; Midwifery and Gynæcology. (2) Three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including antenatal and Infant Hygiene Clinics, also not less than 20 personally conducted cases, five months, one of which must be as a resident intern student; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. Intermediate Medical, Part I., including Anatomy and Physiology, Biochemistry and Histology; Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine, Hygiene, Jurisprudence, and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year, and Part II. completed at the end of the fifth.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A of three years' standing. He must also submit a thesis and pass an Examination before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study or study and practice of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing, and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital or other recognised institution, a six months' course in Trinity College, and then pass a special examination. The minimum time required for the complete course is nine months.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Scholarships and Prizes.—1. Medical and Surgical Travelling Prizes, £100, awarded in alternate years. 2. Bicentenary Memorial Prize, £30, awarded yearly, and given to the Travelling Prizeman. 3. Sir John Banks Prize and Medal. 4. Edward Hallaran Bennett Prize and Medal. 5. FitzPatrick Scholarship, awarded on results of Final Examination (interest on £1000). 6. Medical Scholarship, £20 per annum for two years, awarded in Chemistry, Physics, Botany, and Zoology. 7. Medical Scholarship in Anatomy and Physiology, £20 per annum for two years. 8. Henry Hutchinson Stewart Scholarships, one in Botany, Zoology, Chemistry, and Physics, and another in Anatomy and Physiology, awarded annually and valued at £10 per annum for three years. 9. Henry Hutchinson Stewart Scholarship in Mental Diseases, awarded from time to time, £50 per annum for three years. 10. John Mallet Purser Medal, awarded annually in Physiology. 11. Daniel John Cunningham Medal and Prize, awarded annually in Anatomy. 12. Begley Studentship, £40 per annum for four years, awarded annually. 13. Kingsmill Jones Memorial Prize, awarded annually in Natural and Experimental Science, £15. 14. O'Sullivan Memorial Scholarship, £48, awarded annually for excellency of record in school. 15. Adrian Stokes Memorial Fellowship, awarded every second year, the holder to carry out original work in Pathology and Bacteriology, about £320. 16. De Renzy Centenary Prize in Public Health, awarded annually, £15.

Post-graduate Instruction.—Arrangements have been made, with the approval of the Board of Trinity College, for a post-graduate course of instruction at the School of Physic during the autumn from Monday, Sept. 14th, to Saturday, Oct. 3rd. A limited number of members of the class can reside in college rooms and dine on commons. Women graduates can be accommodated at Trinity Hall.

HOSPITALS AFFORDING RECOGNISED PRACTICE.[1]

The following hospitals afford practice recognised by the Irish Universities and Corporations.

Sir Patrick Dun's Hospital.

Classes both in Medicine and Surgery are held each morning at Grand Canal-street, Dublin, from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon and Resident Physician, with salaries, are appointed annually. Six Resident Pupils are appointed every six months. Twelve Surgical Dressers and twelve Clinical Clerks are appointed each month. There are facilities for women students.

The practice of the hospital is open to all students, and the certificates are recognised by Dublin University, the National University, and Royal Colleges of Surgeons of England, Ireland, and Scotland. It is an official "Treatment Centre" for venereal diseases.

---

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in some of the Irish centres have been described.

Prizes and Medals.—Clinical medals and prizes amounting to about £21 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and Surgery provided they show sufficient merit.

Further information will be supplied by the Hon. Secretary to the Medical Board.

Adelaide Hospital.

Two Resident Surgeons and four or more Resident pupils are elected every six months.

Prizes.—The Hudson Scholarship, £30 and a Gold Medal, as well as the Hudson Prize, £10 and a Silver Medal, are awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology. In addition to this prizes are awarded in gynæcology and dermatology, and in clinical medicine and surgery for junior students. Wallace Beatty Memorial Bursaries are granted at the discretion of the Medical Board at the beginning of the Winter session. The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom.

Further particulars may be obtained from the Secretary of the hospital, Peter-street, Dublin.

Mater Misericordiæ Hospital.

This hospital, under the care of the Sisters of Mercy, containing 410 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery is taught in the Special Wards and in the Dispensary. Surgical operations are performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical, Dermatological, Surgical Diseases, and Accidents; a fully equipped Biochemical Laboratory, a modern Electro-Massage Department, an Electrocardiograph room, and Radiological Department. Instruction is given on Pathology and Bacteriology. Three House Physicians, eight House Surgeons, and 18 Resident Pupils are elected annually. Dressers and Clinical Clerks are appointed regularly and certificates given for merit. Leonard Prizes will be offered for competition annually. Certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses are connected with the Hospital, and Nurses who have passed a qualifying examination can be obtained on application to the Lady Superioress.

Entries can be made with any of the physicians or surgeons, or with the Registrar, 31, Fitzwilliam-square, Dublin. Detailed information may be obtained from the Secretary, Medical Board.

Mercer's Hospital.

This hospital contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the resident posts. There is a large dispensary for out-patients and a modern X ray department. An electrocardiograph has been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. A gold medal is awarded annually to the best student. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A House Surgeon and a House Physician is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from members of the classes.

For further particulars apply to Mr. J. Owens, Hon. Secretary, Medical Board, 36, Lower Baggot-street, Dublin.

Richmond, Whitworth, and Hardwicke Hospitals.

These House of Industry hospitals, North Brunswick-street, Dublin, contain 345 beds—135 for surgical cases, 90 for medical cases, 78 for fever and other epidemic diseases, and an auxiliary wing with 42 beds, devoted mainly to throat, nose and ear, and skin diseases. Two Resident Physicians and two Resident Surgeons are appointed each half year. Resident Clinical Clerks are appointed each quarter, and it has always been the aim of the Medical Board to ensure that each student spends at least six months in residence. In addition, junior students are appointed as extern Clinical Clerks and Surgical Dressers. Women students are eligible on the same terms as men. Ample facilities exist for post-graduate work in the various special departments, as well as in general medicine and surgery. Extensive alterations and improvements have recently been made in the X ray, Electrotherapeutic, and Electrocardiographic Departments. Two open-air huts to accommodate ten patients have been erected in the spacious Whitworth grounds. A new students' residency has been opened recently. This contains facilities for 20 male and 8 female residents.

For further information apply to the Hon. Secretary, Medical Board.

Royal City of Dublin Hospital.

The hospital contains 158 beds and a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. There is a large nursery where special opportunities are afforded for the study of diseases of children, both medical and surgical. There are also special wards for ophthalmic, aural, and gynæcological cases; also a department for the Erlangen Treatment by Deep Therapy. There is a largely attended out-patient department, where students are allowed to attend accidents and dress cases under supervision. Six resident pupils are appointed every three months. A House Surgeon and a House Physician are appointed annually.

For information apply to the Secretary.

Dr. Steevens' Hospital.

This hospital, at Dublin (Kingsbridge), contains 250 beds, of which 175 are now in use. There is accommodation for 10 resident pupils, each of whom is provided with a separate bedroom, and board is supplied by the hospital at a reasonable rate. There is an Electric Massage Department, a "Sun-Ray" and Diathermy Department, and an X Ray Department. There are also two V.D. wards and a largely attended V.D. Treatment Centre, as well as a large ward reconstructed and re-equipped and opened as open-air ward for tuberculous and other diseases of bone (25 beds) for females, two open-air verandahs for male surgical tubercular cases (14 beds).

All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

Dublin—Meath Hospital and County Dublin Infirmary.

The hospital contains 150 beds, available for clinical teaching, both medical and surgical. A separate Fever Block contains 40 beds. Special wards have been set apart for the reception of children.

Jervis-street Hospital, Dublin.

This hospital contains 120 beds and 50 beds are about to be opened. The operating theatre has been equipped with the latest appliances, and a new Radiological Department has been erected and the most modern type of X ray apparatus has been installed in it. Eight Resident Medical officers are appointed each year and facility is thus given to past students of the hospital to acquire experience as House Surgeons. Resident students are provided with apartments, fuel, and light, free of charge. Arrangements have been made by which students of the hospital can have special Fever Training in Cork-street Fever Hospital, free of charge.

Further particulars can be obtained from the Hon. Secretary to the Medical Board.

Rotunda Hospital.

The Rotunda Hospital, Dublin, is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually, and upwards of 1000 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year, and consists of daily clinical instruction in the maternity department, and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. An antenatal dispensary is held three times weekly and all students are encouraged to attend. A special class in gynæcological examination and diagnosis is conducted by the Assistants to the Master. In addition there is a special class in operative obstetrics, limited in number. The pathological laboratory is under the supervision of a skilled pathologist, who gives special classes at intervals. There is a fully equipped X ray installation under the care of a competent radiologist. A ward has been opened for the treatment of infantile conditions, and is under the care of a pædiatrician, who gives instruction in the out-patient department, which is held daily. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M., and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The mess room and sleeping quarters have been decorated recently and reading rooms are provided. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6s., months other than the first £4 4s., three months £12 12s., six months £21. Special gynæcological class £2 2s. per month.

For further particulars apply to the Master, Dr. Bethel Solomons, F.R.C.P.I.

Coombe Lying-in Hospital.

The Coombe Lying-in Hospital and Guinness Dispensary for the Treatment of Diseases peculiar to Women, Dublin, contains 70 beds, and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. There is accommodation for intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Women students can reside in the hospital. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month.

Further particulars may be had on application to the Master or the Registrar at the Hospital.

National Maternity Hospital.

This hospital at Holles-street, Dublin, was established in 1894. The hospital consists of Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children and an antenatal and postnatal branch. Every facility is given for the carrying out of practical work. Undergraduate and post-graduate courses are arranged at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Clinical lectures are given daily and Oral lectures four times per week. The L.M. Diploma is given by special examination, which is held three times a year.

Further particulars can be obtained from P. T. McArdle, Esq., M.B., the Master, or from the Secretary, Holles-street, Dublin.

St. Vincent's Hospital and Dispensary.

This hospital was established at Dublin in 1834, with 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Ferrall gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the McArdle Memorial Prize, value £20. There are a large Extern Department and a new Pathological Laboratory.

Further particulars from Hon. Secretary Medical Board, Wm. Doolin, M.B., F.R.C.S., 2, Fitzwilliam-square, Dublin.

NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students must pass a matriculation examination; the examination taking place in June and September in Dublin, and at certain local centres, includes five subjects, three of which must be Irish, English, and mathematics. All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—(1) Irish. (2) Latin. (3) Greek. (4) French. (5) German. (6) Italian. (7) Spanish. (8) Portuguese. (9) Welsh, or any other modern language approved by the Senate. (10) English. (11) Mathematics. (12) *History.* (13) Geography. (14) Applied Mathematics, or (15) Physics as an alternative. (16) Chemistry. (17) *Botany.* (18) Agricultural Science. (19) Commerce. (20) Music, and for women candidates only (21) Physiology and Hygiene. Students entering for degrees in Medicine or Dentistry, if not already registered by the General Medical Council, must take Irish, Latin, English, Mathematics, and a fifth subject.

The medical degrees granted are:—

M.B., *B.Ch.*, *B.A.O.*; *M.D.*, *M.Ch.*, *M.A.O.*, *Ph.D.*—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

University College, Dublin.

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland. The pre-registration examination in physics and chemistry is taken after matriculation either at the beginning of or during the winter session. The course is of five years' duration and dates from the passing of the pre-registration examination.

Degrees of M.B., B.Ch., and B.A.O.—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination (Part I.) includes Pathology, Materia Medica, Pharmacology, and Therapeutics. Part II. (Third Examination), taken at the end of the Fourth Winter Session, includes Hygiene and Medical Jurisprudence.

The Final Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year after registration, when the curriculum has been completed. The degree of M.D. may be obtained either by examination or on published work.

A Post-graduate Summer Course is held each year, beginning about the middle of June. The D.P.H. Course extends over the year, beginning at the opening of the session.

University College, Cork.

In the School of Medicine students must have passed the Matriculation Examination of the University or some other recognised examination, and a preliminary examination recognised by the General Medical Council.

Medical Students who have passed the First Professional Examination of the Conjoint Boards of Ireland, England, or Scotland may be admitted to the rank of second-year students on making application to the Council. Similarly, students who have passed the Second Professional Examination of the same Boards may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may rank as fourth-year.

The school is provided with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are dissecting-rooms, well-appointed physical, chemical, and biological laboratories, a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs.

Residence of Students.—Students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, and register their addresses each session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Charitable Infirmary and County of Cork General Hospital, Cork North Charitable Infirmary and City of Cork General Hospital, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, Bon Secours, Fever, the District, and Ear, Eye, and Throat Hospitals.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, and in respect of the hospitals from the Secretaries.

University College, Galway.

The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. In the School of Medicine there are 12 Entrance Scholarships, varying in value from £30 to £60 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value from £30 to £40 each, are reserved for Medical Students. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are adundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students.

Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Tuberculosis Hospital and in the Galway Central and Fever Hospitals, containing on an average 350 patients.

Central Hospital, Galway.

In this completely renovated hospital (300 beds), in addition to the Finer Surgical and Medical Departments, there are now Eye and Ear, Throat and Nose, Gynæcological and Obstetrical, Pathological, X Ray, Ultra-Violet Rays, and Electrical and Massage Departments. Students attend from University College, Galway. Medical and Surgical Clinics are held on alternate days during term. One Resident Physician and one Resident Surgeon are appointed every six months. Resident Students are admitted. The hospital is open to qualified medical men for postgraduate work.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.) The University also grants a Diploma in Public Health and a Diploma in Psychological Medicine, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission shall matriculate or fulfil such other test of fitness as may be prescribed by the Senate, or may be exempted from the matriculation examination by having passed similar examinations elsewhere.

For information as to Scholarships and Prizes, inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for Part I. of this examination at the close of the third year, and for Part II. at the end of the Winter Session of the fourth year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has passed in the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The J. C. White laboratories, recently founded, are fully equipped for research in biochemistry and bacteriology. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the Corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, and the diagnosis of cases of infectious diseases. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical Instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum.

Complete information can be obtained from the respective Secretaries.

Royal Victoria Hospital, Belfast.

There are 436 beds. Students eligible for McGrath, McQuitty, Malcolm, Coulter Smyth and Elwood Scholarships aggregate annual value £185. Twelve House Surgeons and House Physicians. Thirty-six resident pupilships, three months each, annually for Senior Students, of which a proportion is allotted to Women Students, Special Departments for Radiology, Clinical Pathology, V.D., Dermatology, Gynæcology, Vaccine Therapy, Electrocardiography, Dentistry, Radium Therapy.

Mater Infirmorum Hospital, Belfast.

This hospital contains 270 beds and is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given daily by Physicians and Surgeons. Surgical operations are performed daily. The out-patient departments in Medicine and Surgery, also the special dispensaries for Gynæcology, Ear, Eye and Throat, Electrotherapeutics, Venereal Diseases are very largely attended and afford valuable opportunities to students for the study of those subjects. A House Physician and two House Surgeons are elected every six months. Resident pupils are admitted as the vacancies arise. Three Exhibitions and a Gold Medal are competed for annually in June. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom.

Belfast Infirmary and Hospital.

There are 1700 beds. Clinical courses are given quarterly, and a course for D.P.H. in Hospital. Intern Venereal Clinic in Infirmary under Corporation scheme. Maternity Hospital recognised for Practical Midwifery training. Particulars may be obtained on application to the Hon. Sec. Visiting Medical Staff. Certificate of vaccination class recognised by Local Government Board. There is a department for Cancer with 32 beds, and X Ray and Bacteriological Departments.

Belfast Hospital for Sick Children.

At the hospital in Queen-street there are 45 beds. Clinical instruction is given. During the Winter and Summer Sessions Courses of Lectures are delivered on the Medical and Surgical Diseases incidental to Infancy and Childhood. Demonstrations in Ophthalmology and Pathology are given, and ample opportunities are afforded in the wards and in the Out-patient Department for gaining a practical and theoretical knowledge of the diseases of Infancy and Childhood. This Hospital grants Certificates in Diseases of Children, which are recognised by the various Examining Bodies. Certificates are also granted for post-graduate study. A Gold Medal is offered for competition at the close of the session.

Maternity Hospital, Belfast.

At this institution in Townsend-street there are 25 beds in constant occupation, and exclusively devoted to Midwifery and Antenatal conditions. There is also a large district. The Queen's University of Belfast have erected a Students' Hostel in connexion with the Hospital where six Students and Post-graduates are received each month. The University Tutor in Obstetrics resides in the Hostel and Students conduct their cases under his supervision. There is a large Antenatal Department and a Department for Venereal Diseases.

Communications should be made to the Hon. Secretary of the Medical Staff.

Ulster Hospital for Children and Women.

At this hospital in Templemore-avenue, Belfast (60 beds), clinical instruction is given to students in Diseases of Children, Gynæcology and Obstetrics. Special departments: Radiology and Actinotherapy, Eye, Ear, and Throat, Dental V.D. Clinic and Antenatal Clinic. Gold Medal awarded annually. Two House Surgeons appointed from students of hospital.

Benn Ulster and Belfast Ophthalmic Hospitals.

At the Benn Ulster Eye, Ear and Throat Hospital, Clifton-street (30 beds), and Belfast Ophthalmic Hospital, Great Victoria-street (30 beds), practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and laryngology are given. Clinical instruction is given daily.

Belfast Fever Hospitals.

City Fever Hospital, Purdysburn (360 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-graduate (D.P.H.) Classes are also held.

Dr. A. Gardner Robb, Lecturer and Medical Superintendent.

Belfast Mental Hospital.

Purdysburn Villa Colony. (1350 beds.) University Lectures and Clinics.

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

CONJOINT EXAMINING BOARD.

The Conjoint Board of the Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

Professional Examinations.—There are three professional examinations, the first of which cannot be completed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognised medical schools at home and abroad.

The first examination consists of Part I. (*a*) Biology, (*b*) Applied Chemistry and Physics; Part II., Anatomy and Physiology. The second examination deals with (*a*) Pathology, (*b*) Materia Medica, Pharmacy, and Therapeutics and Ophthalmology, and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (*a*) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (*b*) Surgery, including Operative Surgery; (*c*) Midwifery, including Diseases of Women and Children, and the Practice of Vaccination.

Diploma in Psychological Medicine.—There are two examinations in connexion with this Diploma: Part I. consists of (*a*) Anatomy and Physiology of the Nervous System; (*b*) Psychology. Part II.: (*a*) Neurology, including Clinical and Pathological Neurology; (*b*) Psychological Medicine, including its legal relationships.

Further information can be obtained from the Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The College issues its Licence in Surgery to practitioners whose names are entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Irish Conjoint Board.

Candidates are examined in General Surgery (paper and oral), Clinical Surgery, Surgical Pathology (oral), Operative Surgery, Surgical Anatomy (paper), and Ophthalmic and Aural Surgery (clinical).

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

Schools of Surgery.

The Schools of Surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Pierefoy Memorial Prize, value £150; Barker Prize, £26 5*s.*; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectus and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Hall entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence.

Candidates must pass two Professional Examinations, called the Primary Examination and the Final Examination, which are conducted at separate times, partly in writing, and partly practically and orally. The Primary and Final Professional Examinations are held twice a year—viz., in June and January, or such other dates as may be determined.

Candidates who produce satisfactory evidence of having passed an examination for a Degree or Licence in Medicine, conducted by any University or Royal College in the British Empire, or by any Foreign University whose Degrees are recognised in the Foreign List of the Medical Register, will be exempted from the Primary Examination.

The subjects for Part I. of the Primary Examination are: Anatomy, Physiology and Histology, including Bio-Chemistry; and for Part II., Materia Medica and Pharmacy, Pathology, and Medical Jurisprudence and Hygiene.

For the Final Examination the subjects are: (*a*) Medicine and Clinical Medicine and Clinical Methods. (*b*) Surgery—Clinical, Ophthalmic and Operative; and Surgical Anatomy. (*c*) Midwifery and Gynæcology, and Practical Pharmacy and Materia Medica (if not taken at Intermediate Examination).

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied by the Registrar at 95, Merrion-square, Dublin.

PHARMACEUTICAL SOCIETY.

THE SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN is recognised by the University of London. The Society conducts examinations for registration as (*a*) Chemist and Druggist and (*b*) Pharmaceutical Chemist. Courses of Instruction are given for these examinations, in the latter case in conjunction with University College.

An Intercollegiate two years' course for the Final Examination for the degree of B.Pharm. of the University of London is also given in conjunction with University College. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates of approved Universities may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories; this degree may now be taken in Pharmacognosy or Pharmacy in the Faculty of Medicine. Several scholarships are also offered. Further information may be obtained from the Dean Prof. Greenish, 17, Bloomsbury-square, London.

WE take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

THE GUILD OF ST. LUKE was founded 66 years ago by a few medical students, chiefly to meet their own religious needs. It now makes a wider appeal, and its membership is open to all students and practitioners of medicine, both men and women, who are members of the Church of England, the clergy of which are eligible as Clerical Associates. The Chapter meets in every month of each term, and a festival service is held yearly at St. Luke's tide. This year the service will be held in St. Paul's Cathedral, on Tuesday, Oct. 21st, at 8 P.M. Besides the parent Guild, there are a Women's Ward and a Hospital Student's Branch in London. There are also Provincial Wards in important Centres, and it is expected that many others will be established. Particulars of the objects and activities of the Guild can be obtained on application to the Secretary, Guild of St. Luke, King's College, Strand, W.C.2.

SAFETY FIRST.

THE medical practitioner has no more urgent need than that of protection against the legal risks arising out of his professional life. It is never too early for a doctor to consider these risks, and it is useful that the senior student should be aware of them, so that he may make up his mind to annul them as soon as his duties call him into relation with the public.

The commonest situations in which the doctor is called upon to refute charges, which may be either openly made against him in law courts, or privately circulated against him to his detriment, are connected with accusations of unskilfulness or negligence. He may be compelled to answer those charges in a law court as a defendant, when he will be punished by the verdict if his defence is unsatisfactory. Or he may be put to serious inconvenience, and loss of professional status and income, if he does not take steps to arrest statements made to his detriment, in which circumstances, also, his appearance in a law court may be necessary this time as the prosecutor in an action for libel or slander. In either case he may incur expenses over which he will have little control, and which may be very heavy, while he will require throughout legal advice as to procedure. The value of this advice will much depend upon how far he is able to assist in the production of evidence, and especially upon any terms of settlement by which a satisfactory conclusion may be reached.

The practitioner may be charged with negligence as a sequel to any diagnosis or any surgical interference, but when these accusations are grouped under headings it will be found that the majority of them fall into two classes. Any dissatisfied patient, who has suffered or who is suffering in any way whatsoever, may attribute either the prolonged disability or the imperfect recovery to faulty diagnosis or wrong surgical methods. The treatment of fractured bones gives rise to the majority of the serious claims for damages. It is here that the alleged failure of the doctor to recognise the real injury is most often made the basis of a charge of incompetence, and it is here that the doctor most urgently requires legal guidance. Sometimes patients, who feel an honest sense of grievance, proceed against the doctor to recover pecuniary damages for unfortunate conditions which they believe to be due to his conduct of their case, and the claims for money may be very large where the patient is no longer able to earn the income which he gained formerly. But many of these charges against the doctor are not honest at all; they are made with the intention of avoiding payment for services received. The dispute may arise in the first instance through ignorance on the part of the patient as to what the best medical service could have done for him, but it will be persisted in through the desire to escape the payment of legitimate claims, or, and worse, through the intent to extort money. No one who is not a lawyer can estimate the factors which will determine the issue of such cases in a law court or the circumstances which make a settlement out of court the fitting course to take—least of all the accused practitioner. Secondly, the medical man may at any moment have to decide whether he will become a legal prosecutor when suffering under libel or slander. All doctors are particularly liable to damage by loose reflections on their skill and conduct, and while they should not pay undue attention to idle gossip a passive attitude cannot always be maintained, and it may become necessary for the doctor to clear his character openly. Success here will depend in an important measure upon the preliminary steps taken, and where the defamed man, smarting under wrong, acts impulsively he may not only fail to put himself right in the public eye, but may actually worsen his plight.

Such are the two outstanding perils which may arise in the professional life of any doctor, and for his protection there exist in this country three great societies, The London and Counties Medical Protection Society and the Medical Defence Union, working upon identical lines in England, while the *Medical and Dental Defence Union of Scotland* guards the doctors of North Britain. These societies are in a sound pecuniary position; they have a large membership; and have a reasonable expectation of increasing their numbers, for in spite of all that happens in the law courts from year to year, and all that is reiterated in the medical press, a number of medical and dental practitioners still do not avail themselves of the security which the societies offer. At the last annual general meeting of the Medical Defence Union, the President, the late Sir Herbert Waterhouse, warned the assembly that accusations and claims against medical practitioners had increased in frequency, while he considered that with the changed conditions of medical practice this increase might be more rapid in the future. Sir Herbert Waterhouse was deeply interested in defence questions, was an assiduous chief of the big organisation over which he presided, and his views have to be taken seriously. Much dissemination of loose statements in the press leads the public to form wrong views and estimates upon medicine, and the rapid conclusions adverse to doctors, thus encouraged, find expression in ill-founded accusations, which are circulated even among educated people. The panel patient is not, in bulk, highly educated, and the approved societies are not, as a rule, unwilling to receive charges against medical practitioners, so that the extension of the work of both the defence associations, which has taken place of late, can only be expected. And the experiences of both of them during the year past reveal how baseless most of the charges brought against medical practitioners are, for it is common experience that proceedings for malpraxis are dropped as soon as it is known that one of these bodies is prepared to defend the practitioner, while in the cases which come to be heard in the courts a verdict is usually returned in favour of the doctor. Both societies emphasise the liability to a charge of incompetence in connexion with the treatment of fractures. Here the patient who dissatisfied with the results of treatment alleges that either it was wrong or the diagnosis was wrong, or both. If the doctor has submitted the injury to X ray examination before stating a diagnosis and undertaking treatment, the defence is usually rendered simple. But if this precaution has not been taken, and a radiogram later appears to conflict with what is stated to be the original view of the doctor, the defence becomes difficult. It is essential in the interests of all concerned that cases of suspected fracture or dislocation should undergo X ray examination preliminary to treatment; if the patients decide against the precaution being taken the responsibility for the future results becomes theirs, but the doctor should keep a record of the fact that his prudent advice has been offered and has not been followed.

The report of the London and Counties Medical Protection Society contains detailed instances where it was impossible for the practitioner to ignore the accusations made against him, and the report of the Medical Defence Union provides similar stories. These painful situations can be cleared up nearly always to the advantage of the practitioner if his defence is conducted promptly along legal lines. These risks to the practitioner begin the moment that he is qualified and recur to the end of the professional career. If the practitioner is very young the charges may be based upon his alleged inexperience as a youth; if he is a senior the suggestion may be made that he is past his work. Both the societies have the same experience in that doctors find their first impulse to obtain protection when the particular need for it arises. That is too late. The societies are insurance societies and in justice to their constituencies cannot defray the legal expenses of persons who are not subscribing members at the time when the trouble arises. It is never too soon to join one of the defence associations.

THE LANCET.

LONDON: SATURDAY, AUGUST 29, 1931.

SAFETY SECOND.

THE present issue of THE LANCET is published as a guide to those who would be doctors, advising them how and where they should study; it is addressed also to any who are already studying, illustrating the careers before them, and whither post-graduate work may lead them. This page is the dividing line between the two sections of the issue, and it was long the custom to make at this point some reflections on medicine as a career which might help parents to choose wisely for their children. To-day the children choose, and to those who have made the choice no finer encouragement can be offered than that contained in words, spoken rather more than 50 years ago, by WILLIAM OSLER, at the opening of a medical session at McGill University:—

> "Some will tell you that the profession is underrated, unhonoured, underpaid, its members social drudges—the very last profession they would recommend a young man to take up. Listen not to these croakers; there are such in every calling, and the secret of their discontent is not hard to discover. The evils which they deprecate, and ascribe—it is difficult to say to whom—in themselves lie; evils, the seeds of which were sown when they were as you are now (students); sown in hours of idleness, in inattention to studies, in consequent failure to grasp those principles of their science without which the practice of medicine does indeed become a drudgery, for it degenerates into a business. I would rather tell you of a profession honoured above all others; one which, while calling forth the highest powers of the mind, brings you into such warm personal contact with your fellow men that the heart and sympathies of the coldest nature must needs be enlarged thereby. For, *consider the practical* outcome of all you gather; the active work for which your four years' study is a preparation. Will not your whole energies be spent in befriending the sick and suffering? in helping those who cannot help themselves? in rescuing valuable lives from the clutch of grim death? in cheering the loving nurses of the sick, who often hang upon your words with a most touching trust? Aye! and in lessening the sad sum of human misery and pain by spreading, so far as in you lies, the knowledge of those grand laws of health transgressed so ignorantly and yet avenged so fatally?"

We have gone back half a century to recapture the almost evangelical fervour with which OSLER as a young man spoke of the profession of medicine and which he retained throughout his life. We speak to those who have already chosen that profession, and the decision may have been rendered difficult by the general and special economic position. It may be worth while to set aside for the moment prudential considerations and to dwell on the medical career in terms of adventure and enterprise. To give point to such reflections we may take a few examples from the lives of men and women who were just showing their fine promise at the time when OSLER gave his address, and whom we have lost but lately. By their pioneer work in physiology and pharmacology, W. D. HALLIBURTON and W. E. DIXON have helped to open the way for an orderly approach to clinical medicine; J. LORRAIN SMITH has done the same through pathology; MARTIN FLACK has applied physiological principles to flying, and reduced its dangers; E. B. TURNER has infused a robust athleticism into countless young lives and redeemed them from sloth and vice; ETHEL BENTHAM has been the first woman to speak for medicine in the House of Commons; ANDREW BALFOUR has grappled with the health problems of empire and made them appear not incapable of solution. For the most part these people found opportunities where others have found little but routine or conformity to precedents. A profession animated by such vitality would not be content to leave the medical staffing of the services where it stands to-day. There was a time when those services which demanded residence abroad attracted the picked men of the training schools, but the medical department of the Army is now 20 per cent. below strength. The medical services in India are being starved by the fear of what political change may bring; yet they hold great possibilities for those who are not deterred by the element of risk. The colonial services, again, offer positions of interest and responsibility which become every year more varied and important. Medical science has already turned much of the West Coast of Africa from pestilence-ridden wilds into reasonably, and sometimes remarkably healthy places, and it would take a lively imagination to foreshadow what conquests are still before medicine in making the colonies, protectorates, and dependencies a safe outlet for our surplus population.

Not that adventure is lacking in the prospect of medicine at home. It may be that the surgical technique which enthralls every third-year student has reached its fastigium, but our greatest surgical experts tell us that this is the dawn of a new period of preventive surgery in which the whole profession will play its part. The opening up of municipal hospitals is likely to provide opportunities for consultation and orderly team-work which will make general practice more satisfying and efficient. All these departments of medicine, indeed, are what we make them—an old and sensible platitude. But the profession will be richer, and the lives of its members richer, if it shows a greater boldness and does not follow too closely the present fashion of counting the cost.

THE MEDICAL SERVICES

NAVAL MEDICAL SERVICE.

There is no change in the position of the naval medical officer that it is necessary to mention. The service needs recruits, but there always will be a certain number of young medical men to whom life in the Royal Navy appeals. To the man brought up in Naval surroundings or with Naval relations a career as a Medical Officer in the Royal Navy offers very definite attractions. In these days his professional knowledge will most certainly not rust anywhere; but especially in the Naval Hospitals will he have opportunities of practising every branch of his profession, except, of course, diseases of women. He can obtain one of the 60 paid specialist appointments. These include medicine, surgery, diseases of the eyes, diseases of nose, ear and throat, radiology, anæsthetics, genito-urinary and venereal diseases, physical training, bacteriology, pathology, and hygiene. He will be encouraged to work hard and play hard. He will see the world under ideal conditions.

The right type of man for a Naval Medical Officer is a good doctor, keen on his work, keen on his play, and unselfish. If the doctor is of this type he is invariably everybody's friend. The Naval Officer and the blue-jacket are quick to recognise a Medical Officer who is keen on his work, thoughtful of his patients, and one who strives after improving the health of the Navy. Such a Medical Officer finds life agreeable, as everyone is ready to befriend him, and nowhere can one find more delightful friends than in the Navy.

Officers who have held appointments as Medical or Surgical Officers in Civil Hospitals for any period prior to entry, after qualifying, are eligible under the regulations to have their seniorities antedated by not more than one year.

To help men to take higher qualifications opportunities are given, when the exigencies of the Service will permit, for medical officers to take post-graduate courses prior to sitting for these higher examinations. A large number of Naval Medical Officers since joining the Navy have taken qualifications such as M.D., F.R.C.S., M.R.C.P., D.P.H., D.T.M., D.O.M.S., &c. It is recognised that this is good for the Navy and good for the officer himself.

WORK OF THE NAVAL MEDICAL SERVICE.

In our large Naval Hospitals the medical, surgical, and specialist work is of a very high standard. The work is very exacting, and it is the aim of the Admiralty to arrange appointments as far as possible so that medical officers have an opportunity of alternating their work, not only at home and abroad, but also ashore and afloat.

To give Naval Surgeons opportunities for professional work has always been a very definite policy of the Admiralty, and within the last year or so this matter has received still further attention.

The General and Specialist Courses have been increased so that, as far as possible, every officer shall have a course of instruction of not less than four months' duration every four years. The number of specialists allowed is now 60 and the specialist allowance is 5*s.* a day.

The total number of Medical Officers in the Navy is about 400, including 1 surgeon Vice-Admiral (Medical Director-General), 6 Surgeon Rear-Admirals, and 20 Surgeon-Captains, and every improvement has been made towards giving increased opportunities of advancement and accelerated promotion to the best men.

The advantages of a career with its period of strenuous clinical work, followed by a period of comparative leisure which can be devoted to study, &c., are laid stress on in the Presidential Address of the War Section of the Royal Society of Medicine delivered on Oct. 10th, 1927.

The work and professional opportunities of the Service Medical Officer are described, but the address is necessarily brief, and it is only by reading between the lines that one can really visualise the field for work which lies before the keen Naval Doctor.

Not only has he this purely medical work to interest him. He has opportunities to emulate some of the great Naval Surgeons of the past, such as Darwin, Huxley, and many others, who have contributed so much to science.

MEDALS AND PRIZES.

Gilbert Blane Medal.—This Medal is awarded annually to the Surgeon Lieutenant Commander who obtains the highest aggregate marks at the examination for promotion to the rank of Surgeon Commander. The award is subject to the approval of the Presidents of the Royal College of Physicians and Surgeons respectively and the Medical Director-General o the Navy.

Other awards and prizes open to Naval Medica Officers are the Chadwick Naval Prize, the North Persian Forces Memorial Medal, and the Parke Memorial Prize.

PLAY IN THE NAVY.

Recreation is a vital part of the Navy, and there is no branch of athletics or field sports in which the Nava Officer does not have an opportunity of trying hi hand. Not only is the champion encouraged bu also the less proficient.

In every home port and on most foreign station there are opportunities for football, cricket, tennis golf, rowing, sailing, swimming, and all other sports On some foreign stations the Naval Officer can ge shooting and riding in plenty, and so cheap that h can indulge in them on his pay alone. In civil life a home only a rich man could get such magnificen shooting as the Naval Officer does is some parts of th world.

PAY AND ALLOWANCES.

Full Pay.

		£		£	
SURGEON LIEUTENANT (short service and permanent service)	from	444	to	487	per annum.
SURGEON LIEUTENANT - COMMANDER (promoted after six years' service)..	„	587	to	621	„
SURGEON COMMANDER (promoted after a further six years' service)..	„	754	to	958	„
SURGEON CAPTAIN (promoted by selection)	„	1092	to	1344	„
SURGEON REAR-ADMIRAL (promoted by selection)		1764			„
MEDICAL DIRECTOR-GENERAL (Surgeon Vice-Admiral) ..		2300			„

Allowances.

An outfit allowance of £50 towards cost of uniform is given.

Allowances when in charge of hospitals and sick-quarters ..	*10s. and 5s. per diem.*
Sixty Specialist allowances of ..	5*s.* per diem.
Allowances to Senior Medical Officers in flag ships ..	5*s.* and 2*s.* 6*d.* per diem.

Accelerated promotion can be gained under certain conditions provision allowance and lodging allowance are paid whe victualling and accommodation are not provided. Servant' allowance is also payable in certain appointments.

The extra allowances alluded to in this table are not to b looked upon as very exceptional. About a quarter of th Medical Officers of the Navy are drawing extra allowances.

The cost of living in the Navy is cheap, and a officer can live on his pay and enjoy life if he is no extravagant, especially if he does not embark i matrimony too early. A small amount of privat means goes much further in the Navy than in civi life. The three vital points—pay, prospects, an promotion—of the naval medical officer can be grasped by referring to the above clear and brief table.

PENSION.

Naval Officers retire at certain ages according to the rank they have attained. Except for those promoted to the 27 higher posts, the usual retiring age is 50 as Surgeon Commander, the appropriate pension according to scale being £552 per annum. With his experience in the Service, together with specialist qualifications, the Naval Medical Officer is able to obtain excellent openings on shore, being still at the age of 50 able to hold his own with his civilian confrères and being professionally at his best.

The scale of pensions is as follows:—

	Maximum retired pay.
SURGEON VICE-ADMIRAL ..	£1100 per annum, on vacating office.
SURGEON REAR-ADMIRAL ..	£929 per annum, at age of 60.
SURGEON CAPTAIN	£828 " " 55.
SURGEON COMMANDER	£552 " " 50.
SURGEON LIEUTENANT-COMMANDER AND SURGEON LIEUTENANT	£414 " " 45.

Officers permitted to withdraw receive gratuities on the following scale:—

	£
After 4 years' full pay permanent service ..	500
" 8 " " " " ..	1000
" 12 " " " " ..	1500
" 16 " " " " ..	2250

Of recent years Medical Officers have been *admitted* into the Navy without entrance examination, and for short service, with the option of turning over to the permanent service, but it is anticipated that it will not be long before the Admiralty will revert to the old established system of entrance by competitive examination twice a year, in batches of about ten officers.

The Medical Director-General of the Navy, Queen Anne's Chambers, Tothill-street, London, S.W.1, would be glad to receive inquiries from prospective candidates.

Dental Branch.

The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of the recently instituted Surgeon Captain (D) is not open to them. They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work, and there is every opportunity for them to maintain a high standard of professional skill.

Candidates are required to produce certificates of birth, registration, and of character, and must be physically fit for active service anywhere. An outfit allowance of £50 is payable to officers finally entered and commissioned. The rank of Surgeon Lieutenant-Commander (D) is attained on the completion of six years' satisfactory service. Promotions to Surgeon Commander (D) and Surgeon Captain (D) are made strictly by selection from the rank next below and are confined to officers who prove fitted in every respect for these ranks. The present establishment of dental officers is: 1 Surgeon Captain (D), 3 Surgeon Commanders (D), 60 Surgeon Lieutenant-Commanders (D) and Surgeon Lieutenants (D).

Provision has been made for candidates who have held, or who, at the time of passing the examination hold or are about to hold, an appointment as Dental Officer in a recognised *Civil Hospital*. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list.

On the completion of two years' service in the rank of Surgeon Lieutenant-Commander (D), dental officers on the Active List are eligible for a three months' post-graduate course at a dental hospital and school at the public expense, and will draw full pay while attending the course.

Pay.—The current rates of full pay for Dental Officers are as follows:—

	£ £
Surgeon Lieutenant (D)	368–453
Surgeon Lieutenant-Commander (D) (promoted after six years' service)	514–672
Surgeon Commander (D) (promoted by selection to fill vacancies in Establishment)	715–916
Surgeon Captain (D) (promoted by selection to fill vacancy in Establishment)	1049–1302

The Regulations regarding Pension and Withdrawal Gratuities are the same as for Medical Officers in the corresponding Ranks.

In 1919, when new rates of pay for all Naval Officers were fixed, it was decided that 20 per cent. of these rates should be considered as due to the then high cost of living. The rates of pay shown above are those payable on and after July 1st, 1931, and represent a reduction of approximately 8 per cent. owing to the decrease in the cost of living. The 20 per cent. above mentioned is to be regarded as variable and subject to change on July 1st, 1933, and thereafter as may be decided, either upwards or downwards according as the cost of living rises or falls.

ARMY MEDICAL SERVICE.

Royal Army Medical Corps.

SINCE the publication of the Royal Warrant of 1926 further improvements have been made in the conditions of service in the Royal Army Medical Corps, but the number of R.A.M.C. officers is some 20 per cent. below strength. This fact militates against the Service, by making the time spent abroad proportionately too long. The situation has interfered with recruiting.

The regulations for admission giving full details should be obtained from the Permanent Under Secretary of State (A.M.D. 1), War Office, Whitehall, London, S.W. 1, and carefully studied. A personal interview with a representative of the Director-General, Army Medical Services, is readily obtainable.

The rates of pay and allowances have been revised favourably, and should prove more attractive than they do, for the opportunities of post-graduate study are generous, and the work is varied, responsible, and interesting. The gratuities after certain periods of service enable an officer, should he so desire, to leave the Service with a capital sum large enough to go a long way towards re-establishing himself in civil life, and, further, the knowledge of the world and the comradeship of his fellow officers that he has gained in the Army will be of no small value to him.

New entrants are commissioned in the rank of Lieutenant, and the first six months of service are spent on probation, during which time they undergo, in addition to their Military training at the Royal Army Medical Corps Depôt at Aldershot, a probationary course at the Royal Army Medical College in London in Hygiene, Pathology, Tropical Medicine, Military Surgery, Recruiting, the prevention and treatment of Venereal Disease, and the elements of Army Administration. At the end of this course, and after qualifying at the necessary examinations, their commissions are confirmed, and they take their places in seniority according to the total marks obtained at all examinations up to that date. Officers Training Corps service with possession of Certificate "B" (Medical) carries a definite value in marks in this total.

An entrant who is holding or about to hold at the time of the entrance examination an approved whole-time Appointment at a recognised Civil Hospital may be seconded while holding such an appointment up to a maximum period of 12 months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to 12 months in respect of the period the appointment was held. This secondment and antedate counts in all respects as commissioned service, except that pay will not be issued for that period. The Army Council are endeavouring to arrange for all officers who have not themselves obtained a civil hospital appointment to be given a house appointment in a civil hospital for six months, shortly after they receive their commissions.

After a total period of one year's service at home the young officer goes abroad, probably to India, for his first tour of foreign service. Here he gains his first practical experience of tropical disease and tropical hygiene, and possibly his first experience of active service on the frontiers of India. His tour abroad lasts five years, with probably six months' leave home during that time. On returning home the R.A.M.C. officer has the opportunity to decide whether he will remain in the Corps or accept the gratuity of £1000 after seven years' service, and try his fortune in civil life. If he elects to remain, he will, between his eighth and twelfth year of service, undergo a course of post-graduate study at the Royal Army Medical College and the London Hospitals of five months' duration, followed by a course of study of a special subject selected by himself, provided he has shown special aptitude in the post-graduate course or during his previous service. During this period of study he remains on full pay, and the fees for the courses are paid by the State. When qualified in his special subject, the officer becomes entitled to specialist pay at 5*s.* per day when holding a specialist appointment. After this post-graduate course the officer probably proceeds abroad again and promotion to Major rapidly ensues, and from that time onward the officer receives regular successive increases of pay, and is eligible for additional and charge pay as well. The Directorates of Hygiene and Pathology and the appointment of two serving officers as Consultants in Medicine and Surgery have been instituted and have proved a marked success, all these appointments being of the rank of Colonel or Major-General.

In addition to the grant of permanent commissions, the War Office offer a number of temporary commissions in the Royal Army Medical Corps, the holders of which may be invited at the end of 12 months' service, if suitable, and provided that vacancies exist, to accept permanent commissions in the Royal Army Medical Corps. If a permanent commission is accepted, the temporary service is allowed to count as the equivalent of permanent service for promotion, increase of pay, and retired pay. These conditions enable the young man to make acquaintance with army life, detriment to his ultimate prospects, before de whether to make a permanent career in the Army Medical Corps.

The possibilities for good workers are very There is scope for original research in tropical dis in preventive medicine, and in bacteriology, as as in the large clinical field open to the speci in Medicine, Surgery or Gynæcology, in Vene Disease, and in Ophthalmology. Child welfare is undertaken systematically by officers of the R Army Medical Corps.

At the same time instruction in administration continuous. The Royal Army Medical Corps essentially organised for war, and one of the lessons the Great War was that trained administrators mu exist to enable the fullest benefit to be obtained fr professional talent. Many appointments carryi administrative responsibility are open to those officers who display capacity for this duty. All officers must be prepared to undertake command and to have a knowledge of Army administration, especially in war. Equally important is the technical training of the Non-commissioned Officers and men of the Corps in such "trades" as Trained Nurse, Nursing Orderly, Masseur, Radiographer, Operating Room Assistant, Laboratory Assistant, Hospital Cook, Dispenser, &c. This training is carried out by the Officers and Nursing Sisters, and opens a large field for those who have ability in lecturing and teaching as well as the power of influencing men.

PAY AND ALLOWANCES.

* Pay Warrant rates less 8 per cent. from July 1st, 1931. The Pay Warrant rates are subject to revision to an extent no exceeding 20 per cent., according to variation in the cost of living. The next revision takes place from July 1st, 1933.

† Rates of Allowance vary from time to time and issues are subject to conditions laid down in Allowance Regulations.

PROMOTION.

Promotion takes place automatically to Captai after 3½ years, and to Major after 12 years' servic provided the officer is qualified and recommended f promotion. Promotion to the higher ranks is selection from those senior in the rank below, special promotion by brevet or otherwise is open officers of the Royal Army Medical Corps.

ADDITIONAL PAY AND CHARGE PAY FOR R.A.M.C. OFFICERS.

(1) Officer not above the rank of lieutenant-colonel, w acting as specialist in a post considered by the Army Cou to merit the grant of additional pay, according to subje or groups of subjects as under.

Operative Surgery, advanced; Medicine; Ophthalmolog Gynæcology and Midwifery; Dermatology and Venere Disease; Otology, Laryngology, and Rhinology; Radiology Anæsthetics; Mental Diseases; Hygiene; Pathology subjects other than above, at the discretion of Our Army Council, 4*s.* 7*d.* daily.

(2) (*a*) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds ..	2*s.* 6*d* daily.	300 beds ..	7*s.* 6*d.* daily.
150 „ ..	5*s* 0*d.* „	600 „ ..	10*s.* 0*d.* „

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates.

	Daily. *s.*	*d.*
(*b*) Senior medical officer, Royal Arsenal, not exceeding	10	0
(*c*) Officer in command of the depôt, Royal Army Medical Corps	5	0
(*d*) The senior officer of the Army Medical Services with an army in the field: A rate to be fixed by the Army Council according to the magnitude of the charge.		
(*e*) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5	0
(*f*) Adjutant R.A.M.C. Depôt	5	0
(*g*) Adjutant R.A.M.C. (Territorial Army)	2	6

RETIREMENT AND RETIRED PAY.

The following are the rates of retired pay:—

1. Retired pay will consist of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible to retire voluntarily on service retired pay.

2. The scale will be as follows, subject to the reduction of 8 per cent. referred to below:—

(*a*) Service element.—£15 a year for each completed year of service as a medical officer.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant-Colonel	150	30	240
Colonel	290	50	390
Major-General ..	440	50	540
Lieutenant-General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together:—

	£		£
Captain and Subaltern ..	300	Colonel	800
Major	450	Major-General ..	1000
Lieutenant-Colonel ..	600	Lieutenant-General	1200

The above rates are those laid down in the Pay Warrant. They have been reduced by 8 per cent. as from July 1st, 1931, and are subject to future variation with fluctuation in the cost of living.

3. Officers with seven and less than 20 years' service as medical officers may be permitted to retire with a gratuity in accordance with the following scale:—

After 7 years' service as a medical officer ..	..	£1000
„ 15 „ „ „	..	£2800
„ 18 „ „ „	..	£3500

The Army Dental Corps.

This Corps is administered by the Director-General, Army Medical Services. Regulations for admission to the Army Dental Corps should be obtained from the Under Secretary of State, War Office, and carefully studied.

OFFICERS: APPOINTMENT AND PROMOTION.

Commissions as Lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

An officer who is commissioned after holding an approved whole-time appointment in a recognised civil dental hospital or in the dental department of a recognised civil general hospital may be granted an antedate covering the period of his appointment, but not exceeding six months, provided that the interval between the termination of the hospital appointment and the date of entry into the Service does not ordinarily exceed six months. The period of such antedate will reckon towards promotion, increase of pay, gratuity or retired pay.

3. An officer is eligible for promotion to the rank of Captain on completion of three and a half years' service and to the rank of Major on completion of 12 years' service in the Corps, provided he has previously qualified in such manner as may be prescribed by the Army Council.

4. Promotion to the rank of Lieutenant-Colonel and Colonel to fill the establishments laid down from time to time for those ranks is made by selection from those senior in the rank below. Dental officers are also eligible for special promotion by brevet.

PAY.

The following are the rates of pay for officers of the Army Dental Corps.

These rates are 8 per cent. below those shown in the Pay Warrant, 1931. The latter are subject to revision to an extent not exceeding 20 per cent. according to variation in the cost of living. The next revision takes place on July 1st. 1933.

	Per diem. £	*s.*	*d.*
Lieutenant	0	18	4
Captain	1	3	0
Captain after 8 years' total service	1	5	10
Captain „ 10 „ „ „	1	7	8
Major	1	12	2
Major, after 15 years' total service	1	16	10
„ „ 18 „ „ „	1	19	2
„ „ 20 „ „ „	2	3	8
Lieutenant-Colonel	2	10	8
Lieutenant-Colonel after 3 years' service as such	2	15	2
Colonel	3	2	2

CHARGE PAY.

The officer in charge of the Dental Laboratories, Aldershot, receives charge pay at the rate of 5*s.* a day if holding the rank of Captain, or 2*s.* 6*d.* a day if holding the rank of Major.

ALLOWANCES.

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the Royal Army Medical Corps.

RETIREMENT AND RETIRED PAY OR GRATUITY.

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' service.

(3) Earlier retirement on gratuity may be allowed:—

After 8½ years'	service as a Dental Officer,	gratuity of £1000.
„ 15 „		„ £2000.
„ 18 „		„ £3000.

The aim of the Corps is the prevention of wastage on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier is reinspected at least once a year and the dental efficiency maintained at the best standard possible.

SWISS M.D. DEGREE FOR FOREIGNERS.—The Universities of Basle, Berne, and Zurich grant the degree of M.D. to medically qualified foreigners under the following conditions. Candidates are required to present an acceptable thesis and to pass a special final examination. Fee 400 Swiss francs (£10). Information on application to the dean of the medical faculty of each university. At Lausanne the doctorate in medicine can be obtained on the completion of one academic year of study (October-July) in the faculty of medicine followed by examination and the presentation of a thesis bearing on the year's study, the laboratory course being chosen in relation to the subject of the intended thesis. The candidate should make written application to the dean of the faculty of medicine, and further information can be obtained in this country from Dr. C. A. H. Franklin, (151, Sandgate-road, Folkestone, Kent), who is hon. secretary of the Lausanne Medical Graduates. The M.D. of Geneva is conferred under the same conditions as in Lausanne.

INDIAN MEDICAL SERVICE.

This service shares in the general conditions of change to which the whole of Indian State and civil affairs are at the present being subjected. While it is the view of many senior officers that the period of depression is passing, the grounds on which this view is held would be challenged by many. At the same time the India Office is inviting applications for permanent commissions on very favourable terms to young members of the medical profession. These terms include a gratuity of £1000 on retirement after six years' service, or one of £2500 after 12 years' service, together with free return passages for those who no longer desire to remain in the service. A frank announcement is made by the India Office, but the admission is made frankly that it is not possible to state at present what, if any, prospects of employment on the civil side will be open to I.M.S. officers under the proposed new constitution. We find it difficult to imagine the abolition of the civil side of the Service, having regard to past magnificent work and present urgent needs.

THE NEW REGULATIONS.

Competitive examination remains suspended for the present and admission to the Service is on written application to the India Office. As sound bodily health is a first essential candidates may, if they wish it, undergo a preliminary examination by a Medical Board which meets weekly at the India Office.

Candidates must be under 32 years of age at the time of application, and must possess a qualification registered in Great Britain and Northern Ireland, under the Medical Acts in force at the time of appointment. Arising out of the recommendations of the Lee Commission the Secretary of State for India in Council after consultation with the Government of India has decided that the Indian Medical Service constituted on the same broad lines as in the past shall be retained primarily to meet the needs of the Indian Army. In order to maintain the necessary minimum war reserve of military medical officers, and to provide for European medical attendance for European officers of the Superior Civil Services and their families, local governments will be required to employ a stated number of Indian Medical Service officers. The Government of India will draw on the same Service to meet the requirements of the civil administration for which they are responsible. For the present 237 such posts have been reserved, and including the leave reserve will provide employment for 302 officers. 212 of these officers will be British medical men and 90 Indians. As the proportion of European to Indian civil officers diminishes these figures will be subject to periodical scrutiny, and, if necessary, to revision. It will be a definite condition of service for all future entrants to the Service that they will be liable to serve on either the civil or the military side. All officers are required to perform one year's military duty subsequent to permanent appointment before they can be considered eligible for civil employment. Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it. On the military side, however, the opportunities for private practice are not great. Service during the war as a medical or combatant officer, or in a position usually filled by an officer, counts towards promotion and pension, and the commissions of officers who before appointment have obtained certain higher qualifications or have held resident appointments in certain hospitals may be antedated by one year.

RATES OF PAY.

The monthly rates of pay for European officers of non-Asiatic domicile in the Service are as tabulated below. The rupee, it may be remembered, has now been definitely stabilised at 1*s.* 6*d.*

Rank and service in rank.	Basic pay.	Overseas pay.	Year of total service.
	Rs.	Rs.	
Lieut.	500	150	First
		150	Second
		150	Third
Captain :—			
1. During first three years' service as Captain.	650	150	Fourth
		£15	Fifth
		£15	Sixth
2. With more than three and less than six years' service as Captain.	750	£25	Seventh
		£25	Eighth
		£25	Ninth
3. With more than six years' service as Captain.	850	£25	Tenth
		£25	Eleventh
		£30	Twelfth
Major :—			
1. During first three years' service as Major	950	£30	Thirteenth and over.
2. With more than three and less than six years' service as Major	1100		
3. With more than six years' service as Major	1250		
Lieut.-Colonel :—			
1. Until completion of 23 years' total service	1500		
2. During twenty-fourth and twenty-fifth years' total service	1600		
3. After completion of 25 years' total service	1700		
4. When selected for increased pay ..	1850		

Note.—Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1) which, owing to the system of accelerated promotion, may be in advance of the time-scale of promotion. Overseas pay is regulated solely with reference to length of total service (column 4). In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the I.M.S. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service. The appointment of Director-General, I.M.S., which is held by an I.M.S. officer, carries pay of Rs.3500 per mensem. The appointment of Director of Medical Services in India, carrying pay at Rs.3200 per mensem, may also be held by an officer of the Indian Medical Service.

Initial rates of pay are based on the assumption that the majority of newly appointed officers will be bachelors. Officers on arrival in India will be posted for one year to specially selected stations. Officers in military employment, when in command or second-in-command of the larger station hospitals receive special allowances. On the civil side there are public health, bacteriological, research, and professorial appointments carrying special enhanced rates. Officers on appointment receive an outfit allowance of £50.

PENSIONS AND ALLOWANCES.

The rates of pensions are as shown in the table below.

Service.	Rates per annum.	Service.	Rates per annum.
After 17 years ..	£400	After 23 years ..	£620
„ 18 „ ..	430	„ 24 „ ..	660
„ 19 „ ..	460	„ 25 „ ..	700
„ 20 „ ..	500	„ 26 „ ..	750
„ 21 „ ..	540	„ 27 „ ..	800
„ 22 „ ..	580		

Note.—The above rates are subject to periodical revision upwards or downwards, to an extent not exceeding 20 per cent. in all, on account of a rise or fall in the cost of living as compared with the year 1919. A deduction of 6 per cent on this account has already been made. Nevertheless the full pension of a lieutenant-colonel cannot be cut below the maximum of £700 under the old rules in the case of officers who entered the service before July 1st, 1920.

There are additional pensions not subject to the above reduction ranging from £65 to £350 per annum for officers who have held high administrative appointments as colonels or major-generals.

Officers on appointment are provided with free passage to India, normally by transport. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be given free passage to India subject to the payment of messing charges. Officers are granted a certain number of return passages home at Government expense during their career. There are special allowances for officers whilst on study leave.

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall, London, S.W. 1. Letters should be marked "Recruitment for I.M.S."

AIR FORCE MEDICAL SERVICE.

THE Air Council attach great importance to attracting into the service the best type of medical man, since on the capacity of the Medical Service depends in a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the Service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely professional as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in his professional work.

The work to be done, therefore, has a high professional interest which, combined with good rates of pay and allowances, offers a career for medical men which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation.

His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

The establishment will consist partly of permanent and partly of short-service officers.

An officer will on first entry be granted a short-service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council if the officer so wishes on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions will be made from officers holding short-service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

For those entrants who desire it the prospect of obtaining a permanent commission is approximately an even one. Experience has so far shown that the officers selected have included the great majority of those desirous of, and suitable for, retention in the service; owing to the fact that the short-service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the point of view of subsequently entering private practice, or who, on entry, have not made up their minds to the adoption of a permanent career in the service and subsequently find that they would prefer to return to civil life.

For certain purposes medical officers may be allowed to count as service their time spent in approved whole-time appointments in civil hospitals under certain well-defined and generous conditions.

Officers who have been selected for permanent commissions may be permitted to attend for a period not exceeding nine months a post-graduate course in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such permission may be granted at any time when the exigencies of the service permit during the first 16 years of service, and when attending these courses officers will receive full pay and allowances.

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be granted in a limited number of cases to officers who show exceptional ability after

ROYAL AIR FORCE MEDICAL BRANCH: RATES OF PAY AND ALLOWANCES.

Rank.	Pay.*			Cash allowances at home rates in lieu of quarters, rations, and servant, if not available in kind (per annum).†		Pay plus allowances per annum.

* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at rates and subject to conditions authorised from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light, rations, and personal attendance are not available in kind. Normally, provision in kind is available for junior officers. "Married" rates of allowances are payable only to married officers who have reached the age of 30 or the rank of Squadron Leader. Rates of allowances abroad are fixed in relation to costs in the particular country, and a colonial allowance is granted in certain commands abroad. The rates and general scheme of allowances are liable to revision as circumstances may require.

the completion of eight years' service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after 16 years' total service, and to that of Group Captain by selection at any period after 22 years' service.

Certain posts in these ranks are reserved for officers fully employed in professional work, such as surgery, pathology, ophthalmology, &c., numbering at present six in all. The number of these posts will be limited only by the needs of the service and by the necessity of observing a similar proportion between the number of reserved posts and the officers from whom they can be filled, as exists between the total number of higher ranks and the remainder of the medical service. Selections for these reserved posts will be made only from officers professionally qualified to hold them. Officers filling the reserved posts will be eligible for selection to the administrative appointments of their rank, and to the highest administrative appointments.

There will be no competitive examination on entry; candidates must be under 28 years of age, be British subjects, the sons of British subjects, and of pure European descent, be nominated by the dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce :—

1. Birth certificate. 2. Medical registration certificate. 3. A declaration containing the following information: (*a*) Age and place of birth. (*b*) That he is a British subject, the son of British subjects, and of pure European descent. (*c*) That he is ready to engage for general service at home or abroad as required. (*d*) The qualifications he is possessed of, and what medical or other appointments he has held (if any). (*e*) That he is willing to fly as a passenger whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants will undergo an initial course of eight weeks, during which they will be given instruction in the special medical aspects of aviation, the organisation and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch.

In order to avoid the necessity for further examinations the position of entrants in order of seniority in the Air Force List will be determined at the end of the initial course by a system of marking and reports on the actual work done during their instruction.

UNIFORM AND EQUIPMENT.

Medical officers are required to provide themselves with the uniform, service dress and mess dress of their rank and with the distinguishing badges of the Royal Air Force Medical Branch. The provision of full dress is entirely optional at present. An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces.

EMOLUMENTS.

The emoluments of medical officers of the Royal Air Force are given in outline above. The rates of pay are fixed on an inclusive basis, and the fact that specialist pay and charge pay are not payable as separate emoluments was taken into account when the rates were fixed. The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919, and 20 per cent. of each of the standard rates is detachable and subject to alteration upwards or downwards in relation to the increase or decrease of the cost of living above or below the cost in July, 1919. Under this provision the current rates in force from July 1st, 1931, represent a reduction of approximately 8 per cent. on the standard rates. The next revision will take effect from July 1st, 1933.

Retired Pay.

The minimum period of service qualifying for retirement on retired pay is 20 years. Standard rates of retired pay are as follows :—

AIR OFFICERS.

Air Vice-Marshal ..	.. £790 to £1010 per annum.
Air Commodore ..	.. £650 „ £950 „ „

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are :—

Rank.	Yearly rate of retired pay.	Compulsory retiring age.
	£	
Air Vice-Marshal ..	1010	60
Air Commodore ..	950	57
Group Captain.. ..	900	55
Wing Commander ..	600	51
Squadron Leader ..	500	48

OFFICERS BELOW AIR RANK.

Age on retirement.	Standard yearly rate of retired pay.	Years of service.	Addition for each extra year of service.*	Deduction for each deficient year of service.*
	£		£	£
40	300	17	15	15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15

52	720	23	22	15
53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

* Limited to five years.

Gratuities.—A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service, namely :—

£1500 if he has 10 but less than 15 years' commissioned service.
£2500 „ „ 15 or more than 15 „ „ „

Short-service officers will be eligible on passing to the Reserve for gratuities on the following scale: £100 for each of the first two complete years of service, £150 for each of the third and fourth complete years, and £200 for the fifth complete year; that is :—

For three years' service on the active list ..	£350
For five „ „ „ „ „ ..	£700

These gratuities will not be payable to officers granted permanent commissions, but their service on a short-service commission will count towards retired pay.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The list for the immediate special courses includes one week's course in chest diseases, from Sept. 7th to 12th, a two weeks' course in general medicine and surgery, from Sept. 14th to 26th, at the Westminster Hospital; diseases of infants, at the Infants Hospital, from Sept. 14th to to 26th; ophthalmology, at the Central London Ophthalmic Hospital, from Sept. 14th to Oct. 10th; general medicine and surgery, at the Metropolitan Hospital, from Sept. 28th to Oct. 10th; and psychological medicine, from Sept. 8th to Oct. 10th, at the Bethlem Royal Hospital.

COLONIAL MEDICAL SERVICE.

THE various Colonial government medical departments employ some 1200 European medical officers and about the same number of qualified Asiatic and African medical officers who are appointed locally. Included in this total are about 60 qualified European women medical officers. About 850 trained nursing sisters and health visitors are employed, most of whom are Europeans. There are large numbers of subordinate personnel, sanitary inspectors, medical assistants, and dressers, most of whom are natives of the areas in which they serve.

Throughout nearly the whole of the Colonial Empire such diseases as malaria, yaws, leprosy, and hookworm disease menace the health of the indigenous people and retard the progress of development. In equatorial Africa sleeping sickness and plague persist, in West Africa yellow fever has not yet been eradicated, and in the Near and Far East outbreaks of cholera and plague occur from time to time. But in addition to tropical diseases, those maladies usually met with in this country are prevalent throughout the Empire.

An officer in the Colonial Medical Service thus has unique opportunities for the practice of his profession. On joining his medical department his duties include medical, surgical, and public health work. He may be posted to an outlying or bush station where he will be responsible for all the medical activities in connexion therewith; or he may be attached for duty at one of the large hospitals. Every encouragement will be given him to pursue any specialist work in which he may be interested in so far as the exigencies of the service permit. Great importance is attached to a candidate's post-graduate experience, as in the outlying districts he will frequently be called on to deal with emergencies without being able to seek the advice and assistance of his colleagues.

VACANCIES.

Vacancies for medical officers may occur at any time of the year, and are dealt with as circumstances require. The almost complete cessation of recruitment during the war period, coupled with the post-war expansion of staffs, particularly in the larger Colonies, resulted in an abnormally high rate of recruitment. The average for the six years, 1924 to 1929, was 104 vacancies per annum. In 1930 the number of vacancies fell to 77, due to the establishments of medical departments being almost at full strength. It is expected that normally some 50 vacancies will be declared annually as the result of wastage through retirement, without allowing for any abnormal increases of staff. Vacancies occur most regularly and frequently in Tropical Africa and Malaya. The vacancies for which candidates are selected from outside the service are those for ordinary medical officers. Appointments for specialists are almost invariably reserved for officers who are already in the service, and who have shown outstanding merit in a particular branch of medicine or surgery. About six vacancies may be expected annually, usually in West Africa and in Malaya, for women medical officers.

QUALIFICATIONS.

Applicants must be under 35 years of age, and preference is given to candidates under 30. For certain appointments candidates must be of European parentage.

Preference will be given to applicants who have held hospital or public health appointments or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose, and throat, or venereal diseases. In the case of women medical officers experience in maternity and child welfare is almost essential.

Every selected candidate will be required to undergo a course of instruction at the London School of Hygiene and Tropical Medicine or at the Liverpool School of Tropical Medicine or at Edinburgh University, before taking up his appointment. The cost of tuition will be paid by the Government, but candidates must make their own arrangements for board and lodging. An allowance of £25 a month will be paid to them monthly in arrear while they are under instruction. Candidates who are successful in obtaining the diploma in tropical medicine and hygiene of London, Liverpool, or Edinburgh are granted a refund of their examination fees. If an officer has not taken a course of instruction in tropical medicine prior to appointment, he is usually required to take one during his first leave of absence and to obtain a satisfactory certificate before he can be confirmed in his appointment.

GENERAL CONDITIONS OF SERVICE.

The actual value of an appointment is often much greater than is indicated by the salary alone. An applicant should take into consideration whether the post is pensionable; whether free quarters are provided; whether any special local allowances are payable; whether free passages are provided on first appointment and when proceeding on leave; and whether free or assisted passages are provided for the wives and children of married officers. If local income tax exists in a colony it is much lower than that payable at home.

While each dependency has its own establishment, the higher posts are normally filled by selection from the Colonial Service generally, any member of which is eligible for vacancies in dependencies other than the one in which he is serving. But transfers from one colony to another are unusual during the early years of an officer's career.

The majority of appointments are pensionable. Officers appointed to pensionable posts serve on probation in the first instance, the probationary period varying in different services—e.g., two years in East Africa, three years in West Africa. Some appointments are temporary, and service in these does not qualify for pension unless the appointment is subsequently made pensionable.

Information as to the conditions and cost of living in the colonies, protectorates, and mandated territories is contained in a publication of that title (Colonial No. 56), which may be obtained from H.M. Stationery Office, price 3s. Further information as to the staffs, the climate, and local conditions will be found in Appendix III. of the Dominions Office and Colonial Office List, which also contains the rules as to leave of absence, free passages, &c. Leaflets concerning nearly all the tropical dependencies are issued for the use of intending settlers and others by the Oversea Settlement Department, Dominions Office, Caxton House, Tothill-street, London, S.W.1. A new memorandum on Medical Appointments just issued by the Colonial Office will be sent without charge on application to the Director of Recruitment.

Applications for medical appointments in the Colonial Service should be addressed to the Director of Recruitment (Colonial Service), Colonial Office, 2, Richmond-terrace, Whitehall, London, S.W.1. For the present no candidate will be considered by the Secretary of State for the Colonies who did not —if of suitable age—serve in some branch of His Majesty's Forces during the Great War, unless his reasons for not having done so are considered entirely satisfactory by the Secretary of State.

APPOINTMENTS FILLED BY THE SECRETARY OF STATE FOR THE COLONIES.

The medical appointments at the disposal of the Secretary of State for the Colonies are confined to those colonies, protectorates, and dependencies which are administered under his directions. They are here classified under the headings (*a*) Tropical Africa, (*b*) Eastern Colonies and Protectorates, (*c*) West Indian Colonies, (*d*) Western Pacific, (*e*) Mediterranean

Colonies, (*f*) an Island Group, (*g*) Middle East. In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified candidates, or in the case of some of the higher posts, by transfer from other colonies. Appointments in Malta are all filled locally. Each colony or protectorate has its own separate medical establishment, but there are grouped services in East and West Africa and in Malaya. Although individual wishes are consulted, officers are liable to be posted or transferred to any of the dependencies within such a grouped service.

Tropical Africa.

EAST AFRICAN MEDICAL SERVICE.

The medical staffs of Kenya, Uganda, Nyasaland, Somaliland, Zanzibar, and the Tanganyika Territory form one service (Northern Rhodesia has its separate establishment), the members of which are liable to be posted or transferred to any of the Dependencies as the exigencies of the service may require. The preferences of individual officers are, however, taken into consideration as far as possible. Selected candidates are appointed as medical officers on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory, and a native language test has been passed. Later on a special course of study must be taken while on leave. Candidates can generally take their wives with them on first appointment. Medical officers (but not health officers) are permitted to take private practice at some stations on the understanding that they give precedence to their official duties. It must be understood that additions to their income from this source are not likely to be substantial, and that the privilege is liable to withdrawal at any time.

Officers are provided with quarters free of rent or the Government may provide temporary accommodation, or an allowance in lieu of quarters may be paid. The salary of a medical or sanitation officer is £600 per annum, rising by annual increments of £30 to £840, and thence by increments of £40 to £920, subject to an efficiency bar at £840. Senior medical officers and senior sanitation officers are paid on the scale £1000 by annual increments of £50 to £1100. Officers who possess the Diploma in Public Health on entering, or who acquire it while in the Service, receive two special increments in the scale.

Officers of the East African Medical Service are permitted to retire with gratuity, if they wish, instead of waiting to retire on pension as follows: (*a*) After nine years' service, of which at least six must have been spent in East Africa, £1000; (*b*) after 12 years' service, of which at least eight must have been spent in East Africa, £1250. If an officer elects to retire with gratuity he thereby forgoes all claim to pension.

The highest grades and salaries in the medical departments are as follows:—

Kenya.—Director of Medical and Sanitary Services, £1500; Deputy Director of Medical Service, £1200; Deputy Director of Sanitary Service, £1200; Deputy Director of Laboratory Service, £1200; Resident Surgical Officer, £1200.

Uganda.—As Kenya.

Tanganyika Territory.—As Kenya.

Nyasaland.—Director, £1300; Medical Entomologist, £1000–£50–£1100.

Zanzibar.—Director, £1400; Deputy Director of Sanitary Service, £1200; Resident Surgical Officer, £1000–£50–£1100.

Somaliland.—Principal Medical Officer, £1000–£50–£1100.

Northern Rhodesia.—Director, £1300; Deputy Director of Sanitary Services, £1200.

There are also the following posts:—resident surgical officers (Kenya and Uganda), £1200; medical superintendent and principal of medical school, Mulago Hospital (Uganda), £1150; sleeping sickness officer (Tanganyika Territory), £1000–£50–£1100; senior bacteriologists (Kenya and Uganda), £1000–£50–£1100. Health officers are selected from the ranks of medical officers as occasion arises.

Leave and Passages.—The normal tour of service is 20 to 30 months (less in Somaliland), after which leave is granted with full salary to an amount of six days for each completed month of residence (or three days when for any reason the officer is not returning to East Africa), exclusive of the periods of the voyages to and fro. Extensions of leave with full salary are given in case of sickness or in the case of officers attending approved courses of instruction. In addition to the above, local leave may be granted up to 14 days a year. Officers serving in Northern Rhodesia are allowed four (or two) days' leave in respect of each month of service.

Free first-class passages are provided for the officer on first appointment and on leave, and in certain cases assistance towards family passages is given.

Pensions.—Officers on the pensionable establishment may retire (or be retired by the Government) on attaining the age of 50 years; but they may be retained in the service, with their own consent, for such further period as the Government may recommend. Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-four hundred and eightieth of pensionable emoluments—i.e., salary and value of free quarters in respect of each month's pensionable service—at the time of retirement, subject to an average of emoluments for the last three years before retirement. For instance, an officer of 25 years' service who has reached the maximum of the long scale receives a pension of about £650.

WEST AFRICAN MEDICAL STAFF.

This service consists of the qualified European male personnel of the medical department of the Gambia, Sierra Leone, the Gold Coast (including Ashanti, the Northern Territories, and British Togoland), and Nigeria (Southern and Northern Provinces, and the British Cameroons).

Officers hold their appointments in the first instance on probation for three years from the date of their first arrival. After passing a language test and being placed on the permanent establishment this period is counted for pension. Officers are not allowed to take their wives and young children out with them without the sanction of the Governor. When, as is usually the case, an officer has obtained permission to be accompanied by his wife a grant of one-half the cost of his wife's passage to and from West Africa is made subject to certain conditions.

Candidates may express a preference for any particular Colony, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony at the discretion of the Secretary of State. Transfers from one Colony to another are made as seldom as possible, and those transferred do not forfeit their claim to pension.

Leave.—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony. Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa. An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances; and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service. Within the above limits, the actual length of each officer's tour will be at the discretion of the Governor. Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months. In addition, local leave may be granted up to 27 days in any one tour.

Appointments and Salaries.—Medical officers for the West African colonies and protectorates are on one list for employment and promotion. The grades and emoluments of the staff in Nigeria are at present as follows:—

Appointment.	Salary.	Remarks.
1 Director of Medical and Sanitary Service.	£1800	Duty allowance £360.
1 Deputy Director, Medical Service.	£1500	Duty allowance £300.
1 Deputy Director, Health Service.		
2 Assistant Directors of Medical and Health Service.	£1400	Duty allowance £280.
3 Specialist Officers	£1300	Duty allowance £260. After five years' approved service the Deputy Director is eligible for a salary of £1400 with duty allowance £280.
1 Deputy Director, Laboratory Service.		
4 Assistant Directors of Medical Service.	£1300	Duty allowance £260.
1 Assistant Director of Health Service.		
1 Director, Tsetse Investigation.	£1200	Staff pay £300.
5 Senior Health Officers	£1050–£50–£1200	Duty allowance £210.
11 Senior Medical Officers	£1000–£50–£1150	Seniority allowance £100.
1 Deputy Director, Tsetse Investigation.	£800–£40–£960	Staff pay £150; Seniority allowance £72.
1 Senior Sleeping Sickness Officer.		
1 Alienist Officer		
1 Research Medical Officer		
1 Superintendent, Dispensers' Training School.		
11 Pathologists	£660–£30–£720–£40–£960	—
13 Medical Officers of Health.		
97 Medical Officers		
3 Lady Medical Officers		

The highest grades and salaries in the other medical departments are as follows:—

The Gambia.—Senior Medical Officer, £1000–£50–£1150.

Sierra Leone.—Director, £1400; Surgical Specialist, £1300; Deputy Director of Health Service, £1300.

The Gold Coast.—Director, £1600; Deputy Director of Medical and Sanitary Service, £1400; Deputy Director of Health Service, £1400; Deputy Director of Laboratory Service, £1300; three Specialist Officers (two surgical, one medical), £1300; two Assistant Directors of Medical Service, £1300; Assistant Director of Health Service, £1300.

The number of specialist appointments is not fixed, officers of outstanding professional merit being eligible for them. There are 20 appointments of the grade of senior medical officer, and eight of senior health officer. Possession of the diploma in public health is usually required for appointment to this grade. Special facilities are granted to study for the diploma during leave. There are at present 29 appointments as medical officer of health. The salary scale is the same as that of medical officers, except that medical officers of health are granted an initial salary at the rate of £800 a year, together with seniority allowance at the rate of £72 a year and staff pay at the rate of £150 a year, half of which is payable during leave. After three years' service on the maximum of the scale, viz., £960 a year, and on undergoing an approved course of study, medical officers of health are eligible, if unpromoted, subject to the recommendation of the Governor, to be placed on the scale £1000 a year rising by annual increments of £50 to £1150 a year, together with seniority allowance at the rate of £100 a year and staff pay as before. The holders of these appointments are not allowed private practice. Candidates must obtain a diploma in tropical medicine and hygiene, or be in possession of a diploma in public health. They are appointed subject to the condition that, if after a period they are considered unsuitable to serve in that capacity, they may be called upon to transfer to the medical side. The salary of medical officer is at the rate of £660 a year, rising by annual increments of £30 to £720 a year. Then, if confirmed in the appointment, £720 a year, rising by annual increments of £40 to £960, with seniority allowance at the rate of £72 a year. Before passing £800, medical officers are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they draw their further increments up to £960 a year. A medical officer who has served for three years on the maximum salary of this scale (£960) without obtaining promotion is eligible, if recommended by the Governor, to be placed on the scale £1000–£50–£1150, with £100 seniority allowance (as for senior medical officers).

Research and Pathology.—The director of the Medical Research Institute, Lagos, and the director of the Medical Research Institute, Accra, receive a salary of £1300 a year, with a duty allowance of £260 a year, rising after five years' approved service to a salary at the rate of £1400 a year and duty allowance at the rate of £280 a year. There are a number of appointments for pathologists and bacteriologists in Nigeria, the Gold Coast, and Sierra Leone. The salary and other conditions attached to these posts are similar to those of medical officers of health.

All officers of the staff, except directors, deputy directors, assistant directors, senior sanitary officers, medical officers of health, research officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at many stations, and no guarantee can be given that an officer will be posted to a station in which he will be able to practise privately. As a general rule, and subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the Staff.

African Medical Officers.—In addition to the membership of the West African Medical Staff, which is limited to British subjects of European parentage, there are a number of Government appointments for African medical officers in the West African Colonies. These appointments carry a salary on the scale £500–£20–£600, and there is a higher scale, £600–£30–£720. In addition, in Nigeria and on the Gold Coast, arrangements have been made for the employment of a few young African medical men temporarily on the hospital staffs, with a view to appointment to the Government service later, if suitable. In such cases a salary of £400 a year is paid.

Eastern Colonies and Protectorates.

MALAYAN MEDICAL SERVICE.

The qualified European personnel of the medical departments of the Straits Settlements, the Federated Malay States (Perak, Selangor, Negri Sembilan, and Pahang), the Unfederated Malay States (Johore, Kedah, Perlis, Kelantan, Trengganu, and Brunei) form one service. Officers are liable to be posted or transferred to any of the territories, though they are generally posted in the first instance to the Straits Settlements or the Federated Malay States.

Medical officers are appointed on the following scale of salaries: £700, rising to £770 during three years' probation; then, if they are placed on the pensionable establishment, rising to £805, and thence by annual increments of £35 to £1120, with a strict efficiency bar at £840. Officers possessing the D.P.H. receive an additional allowance (non-pensionable) of £140.

Above the concluding figure of £1120 there are certain higher appointments, as follows: principal civil medical officer, Straits Settlements, and principal medical officer, Federated Malay States, £1680 each; director, Institute for Medical Research, Federated Malay States, chief health officer, Federated Malay States, and principal, King Edward VII. College of Medicine, Singapore, £1540 each; 12 posts at £1470; and 31 posts at £1190, rising annually by £42 to £1400. Salaries are paid in dollars at 2*s.* 4*d.*

Temporary allowances are at present paid to all Government officers in the Straits Settlements and Federated Malay States: unmarried, 5 per cent. of salary; married, 10 per cent. Private practice by Government medical officers is not allowed, but consultation work with another practitioner is permitted. Information about general conditions in Malaya is obtainable from the Malayan Information Agency, 57, Charing Cross, London, S.W. 1.

Leave.—Eight months' full-pay leave is normally granted: (*a*) after a tour of four years' resident service during the first eight years of resident service; (*b*) after a tour of three years' resident service during the next six years of resident service; (*c*) after a tour of two and a half years' resident service after 14 years' resident service. Additional leave on half-pay may be granted on special grounds. Officers are provided with free passages on first appointment for themselves and their families (i.e., wife and children) up to five persons, inclusive of the officer. On completion of each full tour, free return passages are given to all officers (with wife and children under the age of 10).

HONG-KONG.

Officers are appointed on probation for three years. A diploma of public health is required for a health officer. The present establishment of the medical department is: director of medical and sanitary services, £1500–£50–£1800; deputy director £1300–£50–£1400; senior medical officer and senior health officer, £1200–£40–£1280; malariologist, health officer of port, bacteriologist, each £920–£40–£1280; five health officers, £860–£40–£1220; second health officer of port, assistant bacteriologist, radiologist, each £860–£40–£1220; eight medical officers, £700–£40–£1180. The currency of Hong-Kong is based on the silver dollar. For purposes of local payment salaries fixed in sterling are converted into dollars at the current rate of exchange. If quarters are provided a rental of 7 per cent. on salary is charged. In certain instances a rent allowance is paid instead.

West Indian Colonies.

Jamaica.—There are 44 district medical officers who, if on a whole-time basis, draw £600–£25–£800 with travelling allowance and unfurnished quarters or an allowance in lieu. The public hospital, Kingstown, has a staff of six, the senior medical officer drawing £700–£50–£800. The chief post in the colony is that of superintending medical officer, £1100–£50–£1200. Whole-time officers are not allowed private practice. The age for voluntary retirement is 60. Pension is reckoned at the rate of one-sixtieth of the retiring salary for each year of service.

Trinidad and Tobago.—In Trinidad and Tobago there are about 40 appointments. Government medical officers receive salary at the rate of £400 per annum, rising by annual increments of £25 to £600. An officer appointed to a district receives, in addition to his salary, a travelling allowance varying from £100 per annum in a normal district to £150 per annum, and is allowed private practice, for which there is good scope. Officers employed in institution work receive a duty allowance varying from £50 to £300. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent). There are over 25 appointments. The chief medical officer, Grenada, receives £750, and also an allowance of £50 as bacteriologist. The chief medical officer, St. Lucia, receives £600–£700 plus forage and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. The chief medical officer, St. Vincent, receives £500–£600, with free quarters valued at £40. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government are, in Grenada, on the scale £500–£600, in St. Lucia, £400–£500, in St. Vincent, £400–£450. The Governor has the power to transfer a medical officer from one island to another. Appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The appointments are similar in number and character to those in the Windward Islands, and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £350, and is later appointed to a definite district at a salary varying from £312 to £400–£25–£450, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands. The medical officers, except in St. Christopher and Nevis, receive fees for successful vaccinations, post-mortem examinations, evidence at courts of justice, and certificates of lunacy. They are also, as a rule, allowed private practice. The chief medical officer, St. Christopher and Nevis, receives £930 and a travelling allowance, but is not allowed private practice, except as a consultant.

British Guiana.—There are the following posts in the medical service of the colony: surgeon-general, £1000–£1200 per annum, with consulting practice; medical officer of health, £900; ophthalmologist, bacteriologist, pathologist, each £700: 37 medical officers at £500–£25–£700. Most of the senior posts in institutions carry duty allowances (varying from £50 to £300 per annum) and quarters.

British Honduras.—There are seven assistant medical officers at a salary of £500–£25–£650. The principal draws £825–£25–£850, paid in dollars. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The appointments are pensionable.

In British Guiana, Jamaica, and Trinidad officers are allowed to accumulate full-pay leave (at the rate of six weeks for each year's service) up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay may be taken in addition to six months' full-pay leave.

Western Pacific.

Fiji.—The chief medical officer receives £1000–£50–£1100, with free unfurnished quarters; the medical superintendent, Colonial War Memorial Hospital, £800–£25–£1000, and free quarters: the medical superintendent, Leper Asylum, £700–£50–£950, with completely furnished quarters and one servant, the medical officer of health, £750–£25–£900, no quarters provided. There are 14 district medical officers who receive £500–£25–£725, with partly furnished quarters or £50 house allowance (at the option of the Government) and duty allowance of £50 per annum in districts where no private practice exists. In certain districts horse allowances or car allowances are granted. In others a medical officer is provided with a launch or boat. District medical officers are allowed private practice on the understanding that their official duties are not neglected. In four districts the medical officer is also district commissioner and receives an additional allowance of from £175 to £275 and free partly furnished quarters. In most districts there is private practice, the value of which has been estimated at from £100 to £600 a year.

Western Pacific.—The staff in the British Solomon Islands Protectorate consists of a senior medical officer (£650–£50–£750), two district medical officers and one travelling medical officer (£550–£25–£650), with partly furnished quarters and a local allowance of £50, and a travelling allowance of £200.

In the Gilbert and Ellice Islands Colony there is a senior medical officer (£650–£25–£750), with partly furnished quarters, and one medical officer (£600–£25–£650), with partly furnished quarters or house allowance. There is hardly any private practice in the protectorate or colony.

Mediterranean Colonies.

Cyprus.—There is a director of health (£1000–£25–£1200), an assistant director (£600–£25–£750), and three district medical officers (£400–£20–£600), one of whom is allowed full private practice. The specialist in venereal diseases (£700) and the surgical specialist (£400–£20–£600) are allowed consulting practice.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £730, with private practice. There are also two assistant surgeons with a salary of £600 for 3 years and thereafter £650–£25–£700 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

Island Group.

Falkland Islands.—A colonial surgeon is paid at the rate of £800 per annum, with free furnished quarters, and £200 in lieu of private practice. His assistant receives £700–£25–£800, with quarters, and is not allowed private practice. The offices are pensionable.

Seychelles.—The chief medical officer receives £600 and the resident surgeon £487 10*s.* per annum, with quarters. There are three assistant medical officers, two receiving £487 10*s.*, the other £337 10*s.* per annum, paid in rupees. Private practice is allowed.

St. Helena.—A colonial surgeon receives £550, with fees estimated at £27, and £30 horse allowance. His assistant receives £500 and horse allowance. Private practice is allowed, and such practice, together with the duties of non-Government appointments, is divided between the two officers in a proportion approved by the Governor. The value of these is estimated at about £536.

Middle East.

Palestine.—The grades and salaries of higher appointments in the department of health are: director, £1200, plus £200 expatriation allowance. Deputy director, £900–£50–£1100, plus £150 expatriation allowance. Assistant director (laboratories), specialist surgeon (who is allowed a certain amount of private practice), and five senior medical officers, £750–£25–£950, plus £100 expatriation allowance. One senior medical officer and Government analyst, £550–£25–£750, plus £100 expatriation allowance. Payment is in Palestinian pounds, now equal to sterling. The remainder of the staff is recruited locally. Three months' leave with full pay can be taken every two years. Most of the senior appointments have been or will be made pensionable.

Iraq.—Certain medical appointments are filled normally upon the recommendation of the Secretary of State for the Colonies. Every officer who accepts employment under the Government of Iraq is required to enter into an agreement to serve that Government for a period of 3, 5, 10 or 15 years. The grades and salaries of the principal appointments in the department of health are: inspector-general of health, Rs.1800–100–2800 a month; health specialists, directors of hospitals and institutes, chief medical officers in Mosul and Kirkuk, medical officers of health in Bagdad and Basra, Rs.1500–75–1600–100–2300 a month; medical officers, Rs.1200–75–1800 a month. Posts in the service of the Government of Iraq are not pensionable. Every officer (unless serving on a three years' contract) is required to contribute one-twelfth of his pay to a provident fund, to which the Government makes a contribution equal to one-sixth of his pay.

APPOINTMENTS NOT WITHIN THE COLONIAL SERVICE.

Appointments in the self-governing Dominions and the territories administered by them—viz., Canada, the Commonwealth of Australia (including Papua, Norfolk Island, and the mandated territory of New Guinea), New Zealand (including the Cook Islands and the mandated territory of Samoa), the Union of South Africa (including the mandated territory of South West Africa), the Irish Free State, and Newfoundland—are entirely under the control of the respective Dominion Governments. For information with regard to them application should be made to the High Commissioners or Agents-General in London.

Sudan Medical Service.

This service is responsible for carrying out civil, medical, and public health duties in the Sudan. The country is developing rapidly, and the Medical Department is being increased to meet its growing requirements.

The staff consists of: (*a*) A director, pay £E.1500–£E.2000. (*b*) A senior physician and a senior surgeon to the Khartoum and Omdurman Civil Hospitals, each with a pay of £E.1200–£E.1750. (*c*) An assistant director. (*d*) Medical officer of health, Khartoum Province, at a special rate of pay. (*e*) 31 British "senior medical inspectors" and "medical inspectors" whose pay commences at £E.720 and rises, subject to the recommendation of the director, by five biennial increases to £E.1080, and after 13 years' service to £E.1200. The senior medical inspectors are eligible, by selection, for the four senior posts. All medical inspectors are appointed, in the first place, on probation for two years, and if at the end of that time they are accepted for permanent service under the Sudan Government, the first increase of pay is subject to their passing an examination in Arabic.

In addition to the above there are (*f*) a number of medical officers trained at one of the Syrian medical schools, besides (*g*) Sudanese medical officers trained at the school of medicine at Khartoum. There are several native (*h*) assistant medical officers, who have been given a purely practical training in one of the larger hospitals in the Sudan.

Amongst the attractions of the service are: The great variety of the work met with among many different races of the Sudan; *leave* of 90 days, generally granted every year after the first 18 months of service; *study-leave*, which may be given for some definite purpose, whilst two years towards pensionable service may be granted to those who have special qualifications and experience. The pension for medical inspectors who retire after 20 years' service is not less than £E.500 a year. If, however, he serves for a longer period, or is appointed to one of the higher posts, he will receive a larger pension. Private practice is allowed, but is limited to a few of the larger towns, and may be carried on so long as it does not interfere, in any way, with official duties. These duties include acting as consultant to the principal hospitals and the supervision of medical and public health work, the inspection of schools, the examination of candidates for Government service and pension, and the training of assistant medical officers and native sanitary overseers. The Khartoum Medical School is staffed mainly by members of the medical service, who receive additional remuneration for their work as teachers. A registrar of the medical school is also selected from the service, who receives £E.250 a year extra pay.

Inquiries for further information should be made to the Deans of the Principal Medical Schools, and applications to the Controller, Sudan Government Office, Wellington House, Buckingham Gate, London, S.W. 1.

Southern Rhodesia.—Appointments are under the control of the Government of Southern Rhodesia. Information from the High Commissioner, Crown House, Aldwych, London, W.C. 2.

Malta.—Inquiries should be addressed to the secretary to the Head of Ministry, Malta.

North Borneo.—Application to the British North Borneo Company, 17, St. Helen's-place, London, E.C. 2.

Sarawak.—Appointments are in the hands of H.H. the Rajah. Information from the Sarawak Government Offices, 2, Millbank, London, S.W. 1.

Basutoland, Swaziland, and the Bechuanaland Protectorate.—Appointments are made upon the recommendation of the resident commissioners, subject to the approval of the High Commissioner for South Africa and confirmation by the Secretary of State for Dominion Affairs. These appointments are usually filled by the selection of local candidates.

Shanghai Municipal Appointments.—Inquiries regarding appointments under the Shanghai Municipality, including appointments in the Shanghai Police Force, should be addressed to Messrs. J. Pook and Co., 68, Fenchurch-street, London, E.C. 3.

Chinese Maritime Customs.—Inquiries regarding appointments should be addressed to the Inspector-General of the Chinese Maritime Customs, 26, Old Queen-street, London, S.W. 1.

Consular Appointments.—Application for appointments of a Consular nature should be addressed to the Foreign Office, London, S.W. 1.

Trade Commissionerships.—Applications for appointment as trade commissioner in the colonies and elsewhere should be addressed to the Department of Overseas Trade (Development and Intelligence), 35, Old Queen-street, London, S.W. 1.

WOMEN'S MEDICAL SERVICE FOR INDIA.

AMONG careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. The Service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 44. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. For a further period they are appointed to act temporarily for medical women on furlough. They are then definitely appointed to the charge of hospitals. Private practice is allowed, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.300 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

Rates of pay are as follows :—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	English equivalent* per annum.
1 to 3	Rs.100	Rs.450	£440
4 to 6	,,	Rs.500	£480
7 to 9	,,	Rs.550	£520
10 to 12	,,	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600
16 to 18	,,	Rs.700	£640
19 to 21	,,	Rs.750	£680
22 to 24	,,	Rs.800	£720
over 24	,,	Rs.850	£760

* At rupee value 1s. 4*d*.

Furnished quarters are provided, representing an additional Rs. 150 per mensem.

Leave on average pay is earned at the rate of 2/11ths of the period spent on duty.

Study-leave is granted to the extent of 12 months in the total service and will not be granted more than twice in the course of an officer's service. During study-leave an officer draws half average pay, with a study allowance at the rate of 12*s*. a day during the course of study. Officers of European domicile are entitled to four free return first-class passages from a port in India to a port outside India in their whole service. The first passage is not granted until after the expiry of four years' approved service, and thereafter passages may be granted at intervals of not less than four years. There is a Provident Fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent., which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection in India and England—preference being given to those with Indian experience. Vacancies are few. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Major-General Sir Leonard Rogers, India Office, Whitehall, London. Candidates in India should apply to the Chief Medical Officer, Women's Medical Service, Countess of Dufferin's Fund, Simla and Delhi.

PRISON MEDICAL SERVICE.

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £600, making the pay at present with bonus £456 8*s*. to £738 12*s*.; Medical Officer, Class I., £650, rising by annual increments of £25 to £800, plus bonus, making the pay £797 3*s*. to £953 13*s*. Unfurnished quarters are provided or an allowance in lieu is made. Study-leave is granted annually to two of the whole-time Medical Officers. There are 12 full-time medical officers of Class I. and 15 Class II., and 23 part-time medical officers. The number of vacancies is never large.

SPECIAL DIPLOMAS

DIPLOMA IN PUBLIC HEALTH.

THE following epitomises the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene, or State medicine, as this discipline is variously called. Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council. The diploma is registrable by the Council whose rules on the curriculum become binding on the educational bodies concerned. The new regulations, which came into force in 1924, extend the period of study and postpone the granting of a diploma until at least two years from qualification.

London School of Hygiene and Tropical Medicine.

The course of study for the Diploma in Public Health will *commence on Sept.* 28th in the premises in Keppel-street (Gower-street), the gift of the Rockefeller Foundation, which has excellent laboratories and research rooms, a fine lecture theatre and classrooms, library, and museum. The course, which will extend over a period of nine months' whole-time study, is designed in compliance with the requirements of the General Medical Council, to enable students to proceed to the academic Diploma in Public Health of London University. The curriculum has been planned on very practical lines, and includes, in addition to work with Medical Officers of Health in two selected areas, a large number of visits to places of public health interest. A series of 5 o'clock lectures is given by eminent authorities on special subjects, and these lectures will be open to members of the medical profession as well as to students of the School. The London County Council, the City of London, and various other bodies have placed their resources at the disposal of the School for teaching purposes.

An interesting recent development is the establishment in the School of a University Chair of Medical Industrial Psychology.

English Conjoint Board.

The regulations are as follows: The Examination consists of two Parts. Part I. will be held in the months of January, June, and October, and *Part II.* in the months of January, June, and October in each year. Candidates may enter for Parts I. and II. *separately* or at the *same* time, but they must pass Part I. before proceeding to Part II. The Examination in each part will be written, oral, and practical. Part II. will include a practical examination in Infectious Diseases, Food Inspection, and Inspection of selected Premises. Candidates who fail to satisfy the Examiners in either part may present themselves again at the next Examination on payment of the same fees. Candidates intending to present themselves for either part of the Examination must give 14 days' notice in writing to the Secretary, at the *Examination* Hall, Queen-square, London, W.C.1.

Candidates will be admissible to Examination in Part I. on producing evidence:—

1. Of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery.

2. Of having attended *during a period of* not less than five months at an Institution recognised by the Examining Board in England, practical instruction in (*a*) Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man and to *those* diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 *hours* have been occupied in practical laboratory work. (*b*) Chemistry and Physics in relation to public health, during 90 hours, of which not less than 70 *hours* have been occupied in practical laboratory work. (*c*) Meteorology *and Climatology* in relation to public health, during not less than 10 hours.

Candidates will be admitted to Part II. of the Examination on producing evidence:—

1. Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less than two years, of being *registered by the* General Medical Council, and of having completed the curriculum *for the* Diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification.

2. Of having attended, *after obtaining the registrable* qualification, instruction during not less than 80 hours at an Institution recognised by the Examining Board in England in the following subjects:—(*a*) The Principles of Public Health *and* Sanitation for not less than 30 hours; (*b*) Epidemiology *and* Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during *not* less than 20 hours; (*d*) Sanitary Construction and Planning during not less than *10 hours*.

3. Of having attended for three months the clinical practice *of a* hospital for infectious diseases recognised by the Examining Board in England and of having therein received instruction in the methods of administration. The certificate must state that the candidate has *attended* on one or more days in each week of the three months, that *each attendance* was of two hours' duration, with a total attendance of 60 hours.

4. Of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a Medical Officer of Health, and of having received, from such officer or other competent *Medical Officer during not less* than three hours on each of 60 working days, practical instruction in those *duties and* also those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for children of school *age*, (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food; including meat and milk.

The above certificate (4) must be obtained from a Medical Officer of Health who devotes his whole time to public work, or from a Medical Officer of Health of a Sanitary Area having a population of not less *than* 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

NOTE.—Revised Regulations are applicable to candidates who begin the recognised study of Public Health work after Oct. 1st, 1931.

University of London.

Candidates for the M.D. Degree may offer State Medicine as a subject in which to graduate. The regulations may be obtained on application to the Academic Registrar, University of London, South Kensington.

University of Durham.

The Degree of Bachelor of Hygiene (B.Hy.) and the *Diploma* in Public Health (D.P.H.).—No candidate is admitted to the final examination for the Degree of B.Hy. *unless* he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University whose degrees are registrable on the books of the General Medical Council of the United Kingdom, and no candidate is admitted to the *final* examination for the D.P.H. unless he is a registered medical practitioner, of not less than two years' standing. The course of study for the B.Hy. and D.P.H. extends over a period of not less than 12 calendar months, subsequent to the attainment of a *qualification* registrable by the General Medical Council of the United Kingdom. Candidates for the B.Hy. must attend this course at the University of Durham; candidates for the D.P.H. may attend it at the University of Durham, or at any medical school or *institution* which is recognised by the University. The examination for the diploma or degree is divided into two parts. A candidate *must* pass in all the subjects of

Part I. before being admitted to examination for Part II. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. The examination for Part I. is practical, written, and oral, and includes the following subjects: Bacteriology and Parasitology (including medical entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. Candidates are not admitted to examination for Part I. until after they have completed the prescribed courses of instruction in the subjects thereof. The examination for Part II. includes Hygiene and Sanitation (comprising sanitary construction), Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination is written and oral, and includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—Dwellings, Factories, Workshops, Schools, &c. Candidates are not admitted to examination for Part II. until after they have completed the prescribed courses of instruction in the subjects thereof. Doctor of Hygiene (D.Hy.): Candidates must be Bachelors of Hygiene of the University of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of Public Health.

NOTE.—The courses of instruction for the B.Hy. and D.P.H. are suspended for the year 1931–32.

University of Birmingham.

Under the rules and regulations of the General Medical Council the University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. A Thesis on the Ætiology and Prevention of a Disease of which the candidate has made a special study must be submitted on entry for B.Sc. Part II. The examinations will be held in March and June (Part I.), October and March (Part II.), each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time (in March). The fee for each part of the examination is £6 5*s*. Medical Officers of the Royal Navy who have attended the required course of study at the Naval Medical School, Greenwich, will be admitted to Part I. examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied at the Staff College. Medical officers of the Navy and Army are admitted to Parts I. and II. Examination (D.P.H.) on complying with the requirements laid down for attendance upon Courses of Study. These Courses need not necessarily be attended in the University of Birmingham.

University of Liverpool.

The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The courses may be taken at any time, and students are allowed to work daily in the laboratories.

University of Leeds.

The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in March and September—is in two parts, and is written, oral, and practical. Candidates must pass in Part I. before being admitted to Part II. Instruction in Entomology and Meteorology is given in the first term, and in Sanitary Chemistry and Bacteriology in the second and third terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Academic Sub-Dean of the Medical School.

University of Bristol.

Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than two years' standing as such, and shall have passed the examination prescribed by regulations, which can be obtained from the Registrar upon application.

University of Wales.

Candidates for the Diploma in Public Health, the curriculum for which extends over a period of not less than twelve calendar months, or an academic year of whole-time study covering a period of not less than nine calendar months, subsequent to the attainment of a registrable qualification, must produce evidence of having pursued at the Welsh National School of Medicine courses of instruction in Bacteriology and Parasitology, Chemistry, Physics, Radiology and Electrology, and Meteorology and Climatology in relation to Public Health, and Physiology and Biochemistry in their application to nutrition and hygiene. Candidates must also satisfy the examiners that they have received instruction approved by the University in the Principles of Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. The candidate must produce evidence that he has attended for three months on the clinical practice of a hospital for infectious diseases containing not less than 100 beds, and has received therein instruction in the methods of administration, and that he has for a period of not less than six months been engaged in acquiring a practical knowledge of the duties, routine and special, of a public health administration under the supervision of a medical officer of health. The examination for the diploma is divided into two parts, Part I. and Part II., each of which extends over not less than two days. A candidate must pass in all the subjects of *Part I.* before being admitted to Part II. of the examination. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. Part I. of the examination is practical, written, and oral, and comprises Bacteriology and Parasitology (including immunology, serology, medical entomology), Chemistry, Radiology and Electrology, Physics and Meteorology and Climatology in relation to Public Health, and Physiology and Biochemistry in their application to nutrition and hygiene. Candidates may not be admitted to Part I. of the examination until they have been certified as having pursued the prescribed courses of instruction in the subjects thereof. Part II. of the examination, which is written and oral, comprises: The principles of Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration (including Public Medical Services), and Sanitary Construction and Planning. No candidate can be admitted to Part II. of the examination until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered in the Medical Register before admission to Part II. of the examination. An examination in each part will be held annually. The examination in Part I. will be held in June, that in Part II. in October. Full information may be obtained from the Registrar of the University, University Registry, Cathays Park, Cardiff. Entries for the examination in Part I. must be received by him not later than May 1st, and not later than Sept. 1st for the examination in Part II.

University of Edinburgh.

Candidates for the Diploma in Public Health must be graduates in medicine and surgery of the University, or hold corresponding degrees or registrable medical qualifications which must be registered before admission to examination. The course is divided into two parts for which examinations are held twice yearly. In each part the candidate must pass in all the specified subjects at one examination. Candidates are not admitted to Part II. until they have passed Part I., nor until after the lapse of not less than two years from the date of obtaining a registrable medical qualification. The subjects of the examination are: Part I. (written, oral, and practical), Bacteriology; Medical Entomology and Parasitology; Chemistry; Biochemistry and Physiology in their application to nutrition and hygiene; Physics, Radiology, Electrology, Meteorology and Climatology in relation to Public Health. Part II. (written, oral, and practical), Hygiene, Sanitation, and Sanitary Construction; Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. There is also included practical examinations in Infectious Diseases, Food Inspection, and Inspection of Premises. The course, which extends over an academic year of full-time study, begins in October, and provision is made by the University for instruction in all the subjects. Detailed particulars may be obtained from the Dean of the Faculty of Medicine.

University of Aberdeen.

Every candidate for the Diploma in Public Health must be a graduate in medicine of the University of Aberdeen, or of any other University whose medical degrees are recognised as qualifying for registration by the General Medical Council of the United Kingdom. No candidate will be admitted to the Final Part of the Examination for the Diploma until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, which qualification shall have been registered before such admission. The whole of the prescribed curriculum of study must be undertaken after the candidate has obtained a registrable qualification in medicine, and shall extend over not less than twelve calendar months (or an academic year of whole-time study covering a period of not less than nine calendar months). At least one academic term must be spent at the University of Aberdeen. Candidates shall produce evidence of having complied with the following requirements in respect of study and training:—1. Practical instruction in the following subjects within a laboratory or laboratories approved by the University during not less than 280 hours: (*a*) Bacteriology and Parasitology (including immunology, serology, medical entomology, &c.), in relation to diseases of man and diseases of lower animals transmissible to man; (*b*) Chemistry, Physics Radiology and Electrology, in relation to Public Health; (*c*) Physiology and Biochemistry in their application to nutrition and hygiene; (*d*) Meteorology and Climatology, in relation to Public Health. The above instruction to extend over not less than five months or two academic terms. 2. A course or courses of instruction extending over not less than 120 hours dealing with: (*a*) The Principles of Public Health and Sanitation; (*b*) Epidemiology and Vital Statistics; (*c*) Sanitary Law and Administration (including Public Medical Services); (*d*) Sanitary Construction and Planning; such course or courses to be given at an institution or by a teacher or teachers approved by the University. 3. Practical instruction, clinical and administrative, within a recognised hospital for general infectious diseases; such instruction to extend over three months, and to include 21 daily attendances of not less than two hours each. 4. Practical instruction and experience, during not less than six months (including attendance of at least three hours on each of sixty working days) in the duties, routine and special, of public health administration, under the supervision of a medical officer of health, who shall certify that the candidate has received from this officer or other competent medical officer, practical instruction in these duties and also in those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. (Instruction in (*a*) to (*f*) shall include attendance at the centres, clinics, institutions, and premises concerned.) The medical officers of health recognised for this purpose by the General Medical Council are: (*a*) a medical officer of health who devotes his whole time to public health work; or (*b*) the medical officer of health of a sanitary area having a population of not less than 50,000; or (*c*) in Ireland, the medical superintendent officer of health of a county or county borough having a population of not less than 50,000. The examination for the diploma is divided into two parts, each of which extends over not less than three days. A candidate must pass in all the subjects of Part I. before being admitted to the examination for Part II. In Part II. and also in Part II. a candidate must pass in all the specified subjects at one time.

University of Glasgow.

Degree of B.Sc. in Public Health.—Candidates must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose by the University Court. Candidates must produce evidence (1) that, after they have obtained a registrable Degree in Medicine, a period of not less than two years has elapsed; (2) that, after they have obtained a registrable degree in Medicine, they have, during a period of not less than 21 calendar months, pursued the course of work and instruction prescribed, and have satisfied the examiners in the prescribed examinations.

There are two examinations. Part I. includes the following subjects: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health; (iv) Higher Chemistry in relation to Public Health; (v) Physics and Geology. A candidate must pass in the subjects marked (i), (ii), and (iii) of Part I. at one examination. Part II. includes the following subjects: (vi) Hygiene and Sanitation (including Sanitary construction); (vii) Epidemiology and Infectious Diseases; (viii) Sanitary Law and Vital Statistics; (ix) Public Health Administration; (x) Applied Hygiene. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene may be on a selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.).*—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written and oral, is divided into two parts, Part I. and Part II., each of which extends over not less than two days. No candidate is admitted to either part of the examination until he has completed the prescribed courses of instruction in the subjects of that part. No candidate is admitted to Part II. until he has passed in all the subjects of Part I., nor until after the lapse of not less than two years from the date of his obtaining a registrable medical qualification, nor unless he presents a certificate showing that his name and qualification have been duly registered in the Medical Register. Part I. includes: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health. A candidate must pass in all the subjects at one examination. Part II. includes: (iv) Hygiene and Sanitation (including Sanitary Construction); (v) Epidemiology and Infectious Diseases; (vi) Sanitary Law and Vital Statistics; (vii) Public Health Administration. A candidate must pass in all the subjects at one examination. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like.

University of St. Andrews.

The Diploma in Public Health is open to those who hold a registered medical qualification of the United Kingdom. The examination is in two parts. (1) (*a*) Bacteriology and Parasitology; (*b*) Chemistry and Physics; (*c*) Meteorology and Climatology. (2) Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. Before admission to the first examination the candidate must have held his medical qualification for one year, and before admission to the second examination for two years. Graduates in Medicine of the University of St. Andrews may take part or all of the qualifying classes in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised by the University Court, but holders of other registered medical qualifications must spend at least eight out of the 12 months' curriculum in St. Andrews University. A complete course is given in the Conjoint Medical School, Dundee.

Scottish Conjoint Board.

All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. The examination is divided into two parts.

For Part I. the candidate must produce evidence of having received during a period of not less than five months at an institution recognised by the Board practical instruction in: (*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work; (*b*) Chemistry and Physics in relation to Public Health during 90 hours, of which not less than 70 hours has been occupied in practical laboratory work; (*c*) Meteorology and Climatology in relation to Public Health during not less than 10 hours. For Part II. evidence must be given of having received instruction during not less than 80 hours in: (*a*) The Principles of Public Health and Sanitation for not less than 30 hours; (*b*) Epidemiology and Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours; (*d*) Sanitary Construction and Planning during not less than 10 hours; of having attended for three months the clinical practice of a recognised hospital for infectious diseases; and of having been engaged during a period of not less than six months in acquiring a knowledge of Public Health administration in addition to practical instruction in the duties relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 6 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in March in Glasgow, and October in Edinburgh. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. David Thomson, 49, George-square, and for Glasgow, Mr. Walter Hurst, 242, St. Vincent-street.

University of Dublin (Trinity College).

The Diploma in Public Health is conferred, after examination, under the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least two years before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, 280 hours' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have received instruction in the following subjects: Physics, radiology, electrology, physiology, biochemistry, meteorology, and climatology, the principles of public health and sanitation, epidemiology and vital statistics, sanitary law and administration (including public medical services), sanitary construction and planning; must have studied, practically, outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. The De Renzy Centenary Prize, value about £15, is awarded to the candidate who obtains the highest marks at the June examination each year, provided sufficient merit is shown. A special prospectus may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.

At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health.

University of Belfast.

A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The first part of the examination will have reference to the general principles of Sanitary Science, and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The examination in both parts is held twice a year, in March and June.

Irish Conjoint Board.

Every candidate for the Diploma in Public Health must observe the following rules: 1. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery, and his admission to the Final Examination for a Diploma in Public Health. 2. The curriculum for a Diploma in Public Health shall extend over a period of not less than 12 calendar months subsequent to the attainment of a registrable qualification. 3. Every candidate shall produce evidence of having attended, during a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, practical instruction in—(*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; (*b*) Chemistry and Physics in relation to Public Health; (*c*) Meteorology and Climatology in relation to Public Health. At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be occupied in practical Laboratory work. At least 90 hours must be devoted to Course (*b*), of which not less than 70 hours shall be occupied in practical Laboratory work. At least 10 hours must be devoted to Course (*c*). 4. Evidence of having received, during not less than 80 hours, at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects: (*a*) The Principles of Public Health and Sanitation; (*b*) Epidemiology and Vital Statistics; (*c*) Sanitary Law and Administration (including Public Medical Services); (*d*) Sanitary Construction and Planning. 5. Evidence that he has attended for three months on the clinical practice of a recognised Hospital for Infectious Diseases. 6. Evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health. The examination for the Diploma is divided into two parts. The examination for Part I. includes Bacteriology and Parasitology (with Medical Entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. The examination for Part II. includes Hygiene and Sanitation (with Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination, which is written and oral, includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises—dwellings, factories, workshops, and schools.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Universities of Cambridge, London, Durham, Leeds, Manchester, Edinburgh, Dublin, National University of Ireland, and the Conjoint Board of the R.C.P. Lond. and R.C.S.Eng. now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies.

In London, courses of instruction for the Diploma in Psychological Medicine are given annually at the Maudsley Hospital, Denmark Hill, which has recently been definitely recognised as a school of the University of London. The course consists of two parts, commencing in January, and is adapted for the diploma of the *Conjoint* Board, the University of London, or the University of Cambridge. The parts may be taken separately; also during the year there are other short courses, lectures and demonstrations in psychological medicine.

Maudsley Hospital.

Appointments as clinical assistants are obtainable at the Maudsley Hospital. The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction. A course for the Diploma in Psychological Medicine is held annually from January to June at the Central Pathological Laboratory of the London County Mental Hospitals, which is situated in the Maudsley Hospital. Facilities and grants-in-aid are given for research work in psychiatry and allied subjects at the Laboratory. Inquiries as to lectures should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.; and as to clinical facilities, to the Medical Superintendent at the same address.

Bethlem Royal Hospital.

A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various universities and the Conjoint Board, is held at Bethlem Royal Hospital, Monk's Orchard, Eden Park, Beckenham, twice annually, during the spring and autumn. The fee for the full course is 15 guineas. Part A or Part B, however, may be taken separately at a fee of 10 guineas per part. In addition to the above, clinical instruction in Psychological Medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 A.M. The fee for students is 3 guineas for a period of three months' attendance and for post-graduates a fee of 5 guineas for a like period. A reduction is made to those who attend the Diploma Course. House physicians are appointed at Bethlem Royal Hospital for a term of six months, which may be extended. These appointments are made on May 1st and Nov. 1st in each year, and the vacancies are advertised in the medical papers. Apartments, complete board, attendance, and laundry are provided and also a salary at the rate of £100 per annum. Clinical assistants are often appointed from time to time for periods of three months or longer. These are non-salaried and non-resident posts, but partial board is provided. The Physician-Superintendent, Bethlem Royal Hospital, Monk's Orchard, Eden Park, Beckenham, will supply further particulars.

University of Edinburgh.

Candidates for the Diploma in Psychiatry must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. Candidates are required subsequent to the date of graduation or obtaining a registrable qualification to have held (*a*) a resident appointment for one year in a hospital for mental disorders approved by the Faculty of Medicine, or alternatively (*b*) a six months' appointment as defined in (*a*) and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty of Medicine. There are two examinations for the Diploma. Part I. comprises: 1. Anatomy of the Nervous System. 2. Physiology of the Nervous System. 3. Psychology and Experimental Psychology. Part II. comprises: 1. Neuropathology. 2. Clinical Psychiatry. 3. Clinical Neurology. 4. An additional subject selected by the candidate from a prescribed list. The examinations are held twice yearly in March and July. Candidates who have held an asylum appointment for a period of five years or more may be exempted from the course of study in one or more subjects of the curriculum. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Dublin University.

A post-graduate diploma in Psychological Medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognised institution for the treatment of Mental Diseases for 12 months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Candidates must also attend special courses of instruction and pass a special examination. Details can be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.

This University confers a diploma in Psychological Medicine; application should be made to the Registrars of the Constituent Colleges, University College, Dublin University College, Cork, and University College, Galway, for all information.

DIPLOMA IN TROPICAL MEDICINE.

Although a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Hygiene and Tropical Medicine, Keppel-street, Gower-street, London, W.C.; while the University of Edinburgh, and the English Conjoint Board grant the diploma.

London School of Hygiene and Tropical Medicine.

The course of instruction in tropical medicine and hygiene has been divided into two parts: Section A, a three months' course of clinical and laboratory instruction, and Section B, a two months' course in tropical hygiene. Each section has been so designed that it can be taken independently of the other, and the examinations by the Conjoint Board will follow closely upon the end of the corresponding course of study. This revised course is recognised by the University of London as a course for Associate students. The dates of the courses for the Session 1931–32 are as follows:—Section A (Clinical and Laboratory Instruction): First course, Sept. 29th to Dec. 18th, 1931; second course, Jan. 4th to March 24th, 1932; third course, April 11th to June 30th, 1932. Section B (Tropical Hygiene): First course, Jan. 18th to March 18th, 1932; second course, April 18th to June 17th, 1932. The course of instruction under Section A includes clinical tropical medicine, applied pathology, medical zoology, and elementary bacteriology. Section B comprises instruction in Tropical Hygiene, including, in relation to hygiene, bacteriology, medical zoology, anthropology, and vital and medical statistics. There has been established within the School a new Division of Clinical Tropical Medicine. The instruction in the new Division will be given by the medical staff of the Hospital for Tropical Diseases and by visiting lecturers. In this way the splendid resources of the hospitals of the Seamen's Hospital Society at Endsleigh-gardens; at the Albert Docks, and elsewhere, become available for the clinical instruction of the students at the School.

University of Liverpool.

The University grants a Diploma in Tropical Medicine. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The subjects of examination are (*a*) Parasitology and Tropical Pathology. (*b*) Entomology. (*c*) Tropical Medicine, including Ætiology, Symptoms, Diagnosis and Treatment of Tropical Diseases. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the Laboratory at the University. Applications should be made to the Dean of the Medical Faculty, University of Liverpool.

The University also grants a diploma in Tropical Hygiene (D.T.H.). The subjects of examination are (*a*) Tropical Hygiene (including Sanitary Engineering, Vital Statistics and Epidemiology and Applied Parasitology and Entomology). (*b*) Practical Sanitation. (*c*) Bacteriology. (*d*) Chemistry (including Meteorology and Climatology). Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

University of Edinburgh.

Candidates for the Diploma in Tropical Medicine and Hygiene must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. The course of instruction, comprising a primary and a second course, is given during the autumn and spring terms, October to March, and includes Tropical Hygiene, Bacteriology, Entomology and Parasitology, Diseases of Tropical Climates (systematic and clinical), Tuberculosis, and Venereal Diseases. Courses in the subjects included in the Primary Course may be given during the summer term also. Provision is made in the University for instruction in all subjects.

The examinations are written, oral and practical, and are held at the end of the courses. Candidates are required on the first occasion of presenting themselves for examination in either part to appear for all the subjects of that part. Candidates who fail to pass the entire examination in either part within a period of 12 months after first appearance are required to reappear for all the subjects. The University is included in the list of institutions whose courses of instruction in Tropical Medicine may be taken by officers on appointment to the Colonial Medical Services or during study-leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

English Conjoint Board.

The Board conducts an Examination three times a year for the D.T.M. and H. granted by the Royal Colleges. The regulations are at present under revision. Further particulars from the Secretary, Examination Hall, Queen-square, London, W.C.1.

DIPLOMA IN OPHTHALMIC MEDICINE.

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.

The diploma in ophthalmology (D.O) is granted to registered medical practitioners after passing an examination, held annually in June, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course. Further information regarding these requirements may be obtained from the Dean of the School of Medicine.

English Conjoint Board.

The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in February and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a registrable diploma or a Degree in Medicine and Surgery of a University recognised by the Board.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

University of Cambridge.

The D.M.R.E. is open only to those who have held for at least one year a medical qualification approved by the Committee. The new regulations which came into operation in October, 1928, in some respects materially alter the scope of the Diploma. The course now occupies nine months, beginning in October. The first three months, which can be spent either in Cambridge or in London, are occupied with lectures and practical work in Physics in preparation for the examination for Part I. in January, and an introductory course in Radiology and Electrology. The second three months must be spent in London. The course, includes lectures and clinical instruction in Radiology and Electrology, with clinical practice in the radiological department of a hospital approved for that purpose by the Committee. The examination for Part II. is held in April. During the final three months a candidate must hold a clinical clerkship or similar appointment in a radiological department approved by the Committee, and must then present an exercise in the form of a critical report with notes upon six cases either in Radiology or in Electrology or in both these subjects, illustrating various methods of diagnosis or treatment. Under certain circumstances of previous experience, the third three months may be excused, but the standard of the exercise or thesis is expected to be considerably higher. A number of large provincial hospitals have been approved by the Commitee to take clinical assistants for this part of the course.

Further particulars as to courses and examinations may be obtained from G. Stead, M.A., Cavendish Laboratory, Cambridge, Secretary for the Diploma, or from Dr. A. E. Barclay, Department of Radiology, Medical School, Cambridge, or from Dr. Stanley Melville, British Institute of Radiology, 32, Welbeck-street, London, W. 1.

University of Liverpool.

Candidates before admission to the examination for the D.M.R.E. must possess a registrable qualification approved by the University in medicine and surgery, and must have attended courses of instruction in (*a*) physics (two terms), (*b*) (i.) radiology, and (ii.) electrology during six months in the X ray and electrotherapeutic department of a hospital or hospitals. An examination is held in March each year, the subjects being (*a*) physics, (*b*) radiology and electrology. Examination in either part may be taken separately. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

University of Edinburgh.

Candidates for the Diploma in Radiology (D.R. Univ. Edin.) must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualification from some other licensing body. Candidates are not admitted to the examination for the Diploma until after the lapse of not less than one year from obtaining a registrable qualification, which qualification must be registered before admission to the Examination. The course of study begins in October and extends over a period of not less than three terms. The Examination, which is written, oral, and practical, is in two parts: (*a*) Physics, and (*b*) Radiology. The Examination is held twice yearly—viz., July and October. Full particulars may be obtained from the Dean of the Faculty of Medicine.

Radiology can be taken as the special subject in the examination for Membership of the Royal College of Physicians of Edinburgh, which means that an Honours standard has to be attained.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

English Conjoint Board.

The Board grants the D.L.O. after an examination held in two parts, in June and December. Part I. comprises anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus. Part II. comprises the medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus, and the recognition and use of special instruments and appliances. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of one year of special study of the diseases of the ear, nose, pharynx, and larynx, after obtaining a registrable qualification, or a degree in medicine and surgery of a University recognised by the Board. The fee for admission to each part is 6 guineas.

DIPLOMA IN TUBERCULOUS DISEASES.

University of Wales.

The regulations governing the award of the diploma of T.D.D. prescribe that every candidate must have obtained a registrable qualification in Medicine, Surgery, and Midwifery for at least two years before he can be admitted to the examination. He must have held, for not less than 12 months, a resident medical or surgical appointment on the staff of a Tuberculosis Hospital or Sanatorium, or at an Orthopædic Institution providing not less than one hundred beds for cases of surgical tuberculosis; or shall satisfy the Faculty of Medicine that he has pursued a special study of Tuberculosis equivalent to the above for a period of not less than 12 months. Every candidate must have pursued a course of instruction in the epidemiology, pathology, and bacteriology of tuberculosis extending over one term in the Welsh National School of Medicine, or an equivalent course of instruction extending over at least the same period in an institution approved by the University for this purpose. The examination is held annually in the first week of June. Notice of candidature, together with the entrance fee of £10 10*s.*, and the necessary certificates, must be forwarded to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 1st.

The *Cecil Prosser Research Scholarship*, of the value of £250 for one year, is awarded triennially for research in Tuberculosis.

DIPLOMA IN BACTERIOLOGY.

University of London.

The University of London, grants an Academic Diploma in Bacteriology, the Course being open to (*a*) Graduates in Medicine, Science and Pharmacy of this or another approved University, whose previous training has, in the opinion of the University, fitted them to profit by the Course; and (*b*) registered medical practitioners and other students who, though not graduates, have obtained a qualification and undergone a previous training which, in the opinion of the University, has fitted them to profit by the Course.

A Course necessary to fulfil the regulations of this Diploma has been planned by the London School of Hygiene and Tropical Medicine, Keppel-street, London, W.C., and full particulars with regard to the Academic Diploma may be obtained from the Academic Registrar, University of London, South Kensington, S.W.

FEDERATION OF HEALTH RESORTS OF FRANCE.—A conference of American doctors is announced to be held at Vichy from August 25th to the 28th under the auspices of the Compagnie Fermière de Vichy. An interesting programme has been arranged in the course of which Dr. Durand-Fardel, the President of the Medical Society of Vichy, Dr. Piéry, Professor of Hydrology at Lyons, and Dr. Gustave Monod will discuss the hygienic amenities of Vichy. On the closing day Dr. Max Einhorn, of New York, a well-known authority on dietetics, will address the congress on certain aspects of therapeutic technique in connexion with digestive troubles. The congress will have ample opportunities of visiting the laboratories and installations of the Compagnie, while the visit will be interspersed with occasions of hospit

DENTAL SURGERY

TEACHING INSTITUTIONS IN DENTISTRY.

REGISTRATION on the Medical Register entitles a practitioner to practise as a dentist, although he cannot register as such without degree or licence in dentistry ; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma, and, until registered on the Dentist Register, no dental work under the Additional Benefit Scheme of the National Health Insurance Act can be undertaken.

The Examining Bodies in Dentistry which grant degrees and diplomas in the subject are as follows: Royal College of Surgeons of England, Royal College of Surgeons, Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow, Royal College of Surgeons in Ireland, and the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, St. Andrews, Dublin (Trinity College), Queen's University of Belfast, and the National University of Ireland. The student should apply to the secretaries of the various Conjoint Boards or to the Deans of the medical faculties or medical schools for a syllabus.

TEACHING INSTITUTIONS IN LONDON.

Royal Dental Hospital.

The Royal Dental Hospital of London, School of Dental Surgery, Leicester-square, is a school of the University of London. Women are admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the University of London for the B.D.S. Degree and the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 6 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for four months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Scholarship in Dental Mechanics and Metallurgy, value £25. For full information as to scholarships and prizes, and other matters connected with the course, application should be made to the Dean.

University College Hospital Dental School.

This Hospital and School, situated at the corner of Great Portland and Devonshire-streets, W., has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the *National Dental Hospital*, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A prospectus containing full information as to lectures, fees, and prizes may be had on application to the Sub-Dean for Dental Students, who attends at University College Hospital Medical School, University-street, W.C.1, on Wednesday mornings from 9.30 to 10.30, and at other times by appointment.

Guy's Hospital Dental School.

The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for both general and local anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrators, the dental house surgeons, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. There is a separate room for denture patients affording accommodation for 15 chairs and a separate department for children with accommodation for 20 chairs. The Members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by four demonstrators, a house surgeon, and seven mechanics.

Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. Students who enter for a medical as well as a dental course are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge.

Twelve house surgeons, 20 assistant house surgeons, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, dresser in the children's department, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and local anæsthetic extraction rooms, and probationary dresser. For particulars as to scholarships and prizes, as well as all information, application should be made to the Dean of the Medical School, Guy's Hospital, London Bridge, S.E. 1.

King's College Hospital.

The Dental School is part of the Medical School of King's College Hospital, and was opened in November, 1923. The Dental Out-Patient Department of the Hospital is used for the performance of dental extractions. A large *Conservation* Room with provision for 40 dental chairs has been equipped. Smaller rooms are used for clinical teaching and administrative requirements, and a specially equipped laboratory for training in the art of dental mechanics. An X ray apparatus has been installed for special use in dental skiagraphy. A museum containing a large number of specimens illustrating oral, buccal, dental, and other diseases is available for teaching purposes. The library, lecture theatre, lecture rooms, common rooms, and the refreshment room are all available for the use of students. Courses of study, including practical work, are provided for the degree of Bachelor of Dental Surgery of the University of London, and for the Diploma in Dental Surgery of the Royal College of Surgeons of England. Special arrangements are made for those students who wish to take a medical degree or qualification in addition to a degree or diploma in Dental Surgery.

The following salaried appointments are open to qualified members of the School: Registrar, Resident House Surgeon, Non-Resident House Surgeon, and Tutors in Dental Mechanics, Operative Dental Surgery, and Dental Materia Medica.

Full particulars of the Dental School may be obtained on application to the Dean, or to the Secretary of the Medical School, King's College Hospital, Denmark Hill, London, S.E. 5.

London Hospital.

This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses, in addition to the Theatres, Laboratories, and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, an X Ray Room, and Laboratories for Practical Metallurgy and Prosthesis. A systematic course of instruction is arranged for pupils. The up-to-date Laboratory contains every modern apparatus, and is in charge of a skilled curator and his assistants. Entrance Scholarship: Francis Farmer Entrance Scholarship in Science, value £25; no age limit. Subjects: Chemistry and Physics. Prizes: The Harold Fink Prize in Operative Dental Surgery, value £8 8s.; the "London" Prize in Dental Prosthesis, value £5 5s. Prizes are also offered for competition at the end of each of the courses of lectures in the curriculum. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean of the Medical School.

London (Royal Free Hospital) School of Medicine for Women.

Courses are arranged for women students for the study of dentistry and in preparation for the B.D.S. Degree of the University of London and the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women, in conjunction with the Royal Dental Hospital, Leicester-square.

TEACHING INSTITUTIONS OUTSIDE LONDON.

Birmingham Dental Hospital.

Dean: Cyril Howkins, O.B.E., D.S.O., M.R.C.S., L.D.S. The Dental Hospital, Great Charles-street, has accommodation for 100 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery, including Radiology and a new department for Practical Pathology and Bacteriology. The hospital, both internally and externally is being renovated, and several departments are being reconstructed. The operations performed annually average 61,000, including gold and other fillings crowns, bridges, porcelain inlays, and injections for block and infiltration anæsthesia. The orthodontic department is one of the foremost in the country. The Prosthetic and Mechanical Department is large and well lighted and under a highly skilled instructor who is always present. Application for information as to fees and scholarships must be sent to the Dean of the Medical Faculty, Birmingham University, or the Dean of the Dental Hospital, Birmingham.

Leeds University School of Dentistry.

The School of Dentistry is adequately equipped to provide for the complete training of the dental student. It forms a part of the Leeds School of Medicine whilst the instruction in clinical and mechanical dentistry is carried out in the Dental Hospital. The School is now in occupation of a spacious new building especially designed to the requirements of modern dental teaching. The School is also the dental department of the General Infirmary, and its close association with the work of that institution ensures an adequate supply of clinical material, and enables a fuller insight into the position dental surgery holds in relation to general medicine and surgery, especially with regard to the major diseases and injuries of the head and neck. The courses of study are mainly designed to meet the requirements of the B.Ch.D. and L.D.S. Leeds, but every opportunity is afforded to students preparing for the degrees or diplomas of other licensing bodies. Full-time demonstrators give the instruction in clinical dental surgery, prosthetic dentistry, and mechanics, which is carried out under the supervision and direction of the Professor of Clinical Dental Surgery and members of the Honorary Staff. Special facilities are provided for instruction in Orthodontia, Dental Radiography, Local and General Anæsthetics. Prizes are offered for competition to pupils and students in their respective years of study. Communications should be addressed to the Warden, School of Dentistry, Leeds, from whom a prospectus may be obtained.

Dental Hospital of Manchester.

This hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to met the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of Surgeons of England. Clinical instruction is given in Dental Prosthetics, Operative Dentistry, Diagnosis and Extraction, Orthodontics, Dental Surgery, Radiography, and Anæsthetics by specially appointed Clinical Teachers.

All the courses of instruction are open to women students. Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

Newcastle-upon-Tyne Dental Hospital and School.

This institution has recently become a component part of, and now constitutes the Dental Department in, the University of Durham College of Medicine. A new dental hospital, erected within the grounds of the Royal Victoria Infirmary and equipped with the most modern apparatus, is to be opened at the commencement of the forthcoming academic year, and in future it will be possible to undertake the whole of the dental curriculum (i.e., systematic lectures, dental and general hospital practice, together with the mechanical pupilage) at the College. The Dental Board of the United Kingdom will recognise the school for the purpose of granting its bursaries to students who are able to comply with the conditions laid down by the Board. The composition fees payable by dental students are £110 for all systematic lectures and laboratory work at the College for the B.D.S. (of £100 for the L.D.S.), £50 for dental hospital practice for B.D.S. (or £40 for L.D.S.), £21 for general hospital practice, and £80 for mechanical pupilage. A dental prospectus and any other information may be obtained from the Dean, University of Durham College of Medicine, Newcastle-upon-Tyne.

Devon and Exeter Dental Hospital.

The hospital at 24, Southernhay West, Exeter, is open on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, and patients are admitted between the hours of 9.30 and 11 A.M. This hospital is being amalgamated with the Royal Devon and Exeter Hospital.

SCOTTISH TEACHING INSTITUTIONS.

Edinburgh Dental Hospital and School.

The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. A large and important extension of the existing buildings has now been opened. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital.

This hospital is located at 158, Renfrew-street, and 15, Dalhousie-street, Glasgow. The school is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, Radiology, Anæsthetics, and Dental Materia Medica. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extra-mural schools where special provision is made for Dental Students. The new Dental Hospital and School will be open in October. The new Hospital will be equipped with all modern methods for teaching students.

Glasgow Royal Infirmary.

Dental Department: The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, three months; Surgery, six months; Medicine, six months; Materia Medica, three months. Clinical Medicine (three months) and Clinical Surgery (six months) are taken at the Royal Infirmary.

IRELAND.

Dental Hospital of Ireland.

All Dental Students who have passed their Second Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean, at Lincoln-place, Dublin.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. W. P. E. McIntyre to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

The following appointments are notified: Surg. Lt. W. F. Lascelles to *Pembroke*, Surg. Sub-Lt. H. A. Lockhart to *Victory*, and Proby. Surg. Sub.-Lt. P. M. Coats to *Enterprise*.

ROYAL ARMY MEDICAL CORPS.

Maj. W. W. Pratt is placed on the half-pay list on account of ill-health.

Lt. (on prob.) A. Macdonald is restd. to the estabt.

The undermentioned to be Lts. (on prob.): T. M. R. Ahern, G. Herbert, R. Johnston, J. B. George, G. A. Kane, H. V. Tighe, W. B. F. Brennan, 2nd Lt. J. C. Barnetson (from Gen. List, T.A., Edinburgh, Univ. Contgt., O.T.C.), and J. K. Chappell

The undermentioned Lts. (on prob.), are secd. under the provisions of Art. 213, Royal Warrant for Pay and Promotion: T. M. R. Ahern and H. V. Tighe.

ARMY RESERVE OF OFFICERS.

Maj. C. W. Bowle to be Lt.-Col.

TERRITORIAL ARMY.

J. E. Foran (late Flight Lt. R.A.F. Med. Serv.) to be Lt.

ROYAL AIR FORCE.

Flight Lt. Edward Alexander Rice is transferred to the Reserve, Class D ii.

INDIAN MEDICAL SERVICE.

Lt. G. F. Condon to be Capt. (prov.).

The undermentioned Capts. (prov.) are confirmed in rank: T. C. Ramchandani, M. G. Kelly, T. C. Puri, H. W. Farrell, H. S. Waters, P. Shannon, and J. S. McMillan.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 15TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 19 (last week 25); scarlet fever, 1146; diphtheria, 716; enteric fever, 64; pneumonia, 428; puerperal fever, 37; puerperal pyrexia, 111; cerebro-spinal fever, 34; acute poliomyelitis, 11; encephalitis lethargica, 10; continued fever, 1; dysentery, 3; ophthalmia neonatorum, 96. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 18th–19th was as follows: Small-pox, 35 under treatment, 2 under observation (last week 46 and 2 respectively); scarlet fever, 1136; diphtheria, 1399; enteric fever, 15; measles, 145; whooping-cough, 353; puerperal pyrexia, 39 (plus 7 babies); encephalitis lethargica, 212; poliomyelitis, 5; "other diseases," 131. At St. Margaret's Hospital there were 13 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 9 (2) from measles, 1 (1) from scarlet fever, 18 (7) from whooping-cough, 21 (2) from diphtheria, 50 (13) from diarrhœa and enteritis under two years, and 15 (2) from influenza. The figures in parentheses are those for London itself.

Two deaths from measles were reported from Wakefield, no more than 1 from any other large town. Liverpool reported 3 deaths from whooping-cough; Bradford, 3 deaths from diphtheria. Diarrhœa was credited with 6 deaths at Birmingham, 4 at Liverpool, and 3 at Bolton.

The number of stillbirths notified during the week was 280 (corresponding to a rate of 42 per 1000 births), including 47 in London.

PUBLIC HEALTH SERVICES

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1930 statistics of Edinburgh, Liverpool, and Nottingham :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Edinburgh .. (425,951)*	17·2	14·2	0·99	1·68	2·2	2·3	82/32	46	8·1
Liverpool .. (879,657)†	21·5	12·8	1·40	1·23	2·5	1·4	82/33	40	4·0
Nottingham . (266,800)‡	17·0	12·8	1·14	1·44	2·2	2·6	75/—	32	3·7

Registered stillbirths per 100 live births: Edinburgh, 5·4; Liverpool, 4·1; and Nottingham, 4·7.

* R.-G. (Scotland) estimate. The Census 1931 shows it to be an underestimate by about 13,000.

† Local estimate for 1930, and about 24,000 in excess of Census figure (1931).

‡ R.-G. estimate for 1929, and about 2000 below the Census figure (1931).

Edinburgh.

Dr. John Guy, who succeeded Dr. William Robertson in September last, tells us that the recent census shows the population to have been underestimated by about 13,000. Except for diphtheria, the city was comparatively free from serious epidemics. During the past five years, and especially during the last two years, notifications of diphtheria have increased. In 1930 there were 1102 notifications with 71 deaths, a case-fatality of 6·4 per cent. Dr. W. T. Benson reports that 1086 cases were admitted to hospital, and that the type of the disease was more severe. Intubation was performed in 19 cases, of whom 6 died; tracheotomy in 9 cases, of whom 8 died; and intubation followed by tracheotomy in 8 cases, of whom 3 died. The severer type was shown by a paralysis rate of 7·1 per cent. In the 62 fatal cases, death occurred in 22 within 48 hours of admission. Suction treatment in suitable cases was an unqualified success, and the Electro-Atmos pump proved to be an ideal instrument for the purpose. Dr. Benson cannot understand why the practitioner delays the administration of antitoxin for the bacteriological result, when there are obvious and severe clinical manifestations.

Distressing cases are given to illustrate the existing housing shortage. As the result of a survey of the whole city, 5199 houses have been earmarked for demolition, in addition to those already scheduled. The three-years programme for the purpose of the Scottish Act is to build 1500 houses per annum, 750 of which are to be reserved for tenants dishoused in clearance areas. One result of the Local Government Act will be the amalgamation of the school medical service with the health department. For the treatment of the sick poor the transfer from the public assistance committee to the health department cannot be completed until certain hospital reorganisation has been carried out. Pilton hospital (120 beds) had already been transferred, and Craigleith hospital (250 beds) came under public health control on May 16th. The hospitals at Craiglockhart and Seafield remain under the care of the public assistance committee pending arrangements for separate administration. Dr. John Keay, medical superintendent of Bangour mental hospital, which has also been transferred to the Town Council, says 367 cases were admitted during the year, of which 24 per cent. were voluntary patients. The average number of occupied beds during 1930 was 1031, as compared with 982 in the previous year. Dr. Keay suggests that Edinburgh should have facilities for the treatment not only of mental disorders from the earliest appearance of symptoms, but also for functional types of nervous illness, which, untreated, are apt to drift along to a complete breakdown, and that the establishment of a nervous and mental clinic, with wards in one of the hospitals and an active social service department, would meet this need. Gogarburn certified institution at present accommodates 150 mental defectives, and extensions in progress will increase the accommodation to 500 beds.

In October, 1930, a combined inquiry as to the prevalence of tubercle bacilli in market milk by the health departments of Edinburgh, Glasgow, Aberdeen, and Dundee, assisted by the Hannah Institute, and coördinated by the department of health for Scotland, was begun. The inquiry will last for two years, and a uniform bacteriological technique has been agreed. Samples will be taken of raw milk as delivered by the farmer, of pasteurised milk, and of milk as retailed by the dairies. This scheme in Edinburgh will mean a large increase in the number of milk samples examined for tubercle. Two-thirds of the milk samples will be examined by the university and one-third by the veterinary department. The opportunity is also being taken of estimating the prevalence of *Bacillus abortus* in market milk, and towards the end of the year a systematic examination of the spleen and sublumbar glands of guinea-pigs inoculated under the tubercle scheme was instituted. Serums submitted for the Widal have also been tested for bacillus abortus. Two positive results, one in February and the other in November, were obtained. The patients were males, aged 32 and 20, respectively. Some of the symptoms resembled enteric, and the illnesses lasted 6 and 13 weeks, respectively. The disease appeared to have been contracted elsewhere than in Edinburgh. Both cases recovered. It is suggested that as the susceptibility in cattle increases with age the same may be true for man, and explain why children are so seldom affected when the comparative frequency of milk infection is taken into account.

The report of Dr. David Lees on the V.D. work raises many interesting points. During the last five years there has been a progressive decrease in cases of inherited syphilis under one year, attributed to the work of the antenatal treatment centres. Of 22 cases of ophthalmia neonatorum treated in hospital complete vision was restored except for the loss of vision in one eye in one child. This child was admitted to hospital 12 days after birth, when the eye was already irreparably damaged. Dr. Lees is not satisfied that the best results are being obtained either in the prevention or treatment of this disease. Vulvo-vaginitis cases in young children numbered 22, and in-patient hospital treatment is urged for this intractable condition, to prevent the infection spreading to other children. Most of the cases result from the children sleeping in the same bed as an infected parent. Dr. Lees finds, after reviewing the cases of syphilis treated during the last 10 years, only one case of neuro-syphilis after a full course of treatment. Intravenous injections of tryparsamide are used for neuro-syphilis, with striking effect, and malarial treatment is found to give good results. Of 45 cases of general paralysis treated by the latter method, over 30 per cent. are well, physically and mentally, and are at work. Although 80 per cent. of the patients remained under treatment until considered cured, the 20 per cent. of defaulters in 1930 represents 693 patients, many of whom are still infective. The follow-up by visiting nurses has produced good results in the case of the women, but the residue, who refused to return for treatment, constitute a careless and inconsiderate group who do not mind whether they spread disease or not. If there could be some further method of control of infected patients, Dr. Lees thinks the defaulter rate could be reduced to a negligible quantity.

Liverpool.

Dr. A. A. Mussen says the health of the city was most satisfactory during the year, notwithstanding a severe outbreak of diphtheria, which taxed the accommodation in the infectious hospitals to the full. There were 4023 cases with 236 deaths, a fatality-rate of 5·9 per cent. Nine cases of anthrax were treated at Fazakerley hospital with serum without recourse to surgical excision of the local lesion. There were 2 deaths, one of a tannery hand, who had been 5 days ill on admission, and the other of a dock labourer, who had been ill 3 days and was almost moribund on admission. There were 6 cases of psittacosis, 5 being residents in one institution. All recovered. Five were associated with the handling of a green Amazon parrot, which died. One case of undulant fever removed to hospital had been taken ill 2 days after returning from a holiday in Flintshire. The symptoms resembled typhoid fever.

During the last half of 1929 arrangements were made to anticipate the operation of the Local Government Act. A public assistance committee was formed, consisting of 60 members of the City Council and 30 coöpted from the West Derby guardians and persons interested in social work. On April 1st all the activities of the guardians were transferred to the public assistance committee, with the exception of functions under the Children Act, 1908, and the Vaccination Acts. The 11 institutions transferred have a total bed accommodation of 9892. As a preliminary measure to determining the best use for these institutions, all the hospitals are being administered by the city hospitals' committee on behalf of the public assistance committee. These formerly poor-law hospitals were in the habit of admitting non-notifiable infectious diseases from the county borough of Bootle and many townships round Liverpool, and this arrangement will be continued for the present. The districts of the 12 public vaccinators and of the 4 vaccination officers are also being continued as before.

The new city abattoir is rapidly nearing completion, and will be ready for occupation in September, 1931. The site is about 3 miles east of the Liverpool town hall, and has an area of 15 acres, with a further 4 acres to be acquired. A plan is included in the report. The buildings and equipment are arranged on the most hygienic lines, and Dr. Mussen draws attention to the bathing and washing arrangements and special clothes lockers provided for the slaughtermen, and also to the isolation slaughter-house block, which is to be used for the slaughter of any animal showing signs of disease or injury. All the available space has been taken up by the traders, and the trade estimate for the annual number of animals to be slaughtered is: 66,500 cattle, 47,200 calves, 586,300 sheep, and 108,200 swine. In addition, the carcasses of imported meats will much exceed in number the animals slaughtered. A new centre for estimating atmospheric pollution has been opened in a residential area at the Carnegie Welfare Building, and a comparison of the results with those obtained at the Netherfield-road centre in a smoky district shows that the total atmospheric pollution does not much exceed one half. The approximate demand for domestic fuel in Liverpool is 20,000 tons weekly, but the available supply of smokeless fuel is only about 1400 tons, so that unless the output of the smokeless fuel is greatly increased, or more progress made in the matter of gas and electric heating, the domestic smoke nuisance cannot improve. The firing of domestic chimney-flues is a common offence, and 2520 convictions were obtained by the police during 1930, as compared with 2320 in the previous year. There are only two boiler-plants working with pulverised fuel, and the difficulty previously experienced by the caking of the fuel, and the choking of the burner through the moisture content of the fuel, has now been overcome.

The number of inhabited houses in the city is 162,500. Up to the present 19,307 houses and 169 flats have been built by the City Council, and it is anticipated that 13,000 more houses will be built during the next five years. Progress has been made with two large unhealthy areas known as "Queen Anne-street" and "Gerard-street." The former involved 434 houses and a population of 2876. The Ministry's order made in November, 1928, was quashed in the King's Bench Court, but subsequently confirmed on appeal by the House of Lords, and the judgment given on March 23rd, 1931, is given in full, together with a plan of the area. The Gerard-street area is being dealt with as a clearance area under the 1930 Act, and the Minister of Health has now confirmed the compulsory purchase order. It involves 398 houses and a population of 3430. Of the 13,000 municipal houses included in the five-years programme, 3000 are to replace houses demolished in clearance and improvement areas and individual unfit houses.

Nottingham.

Dr. Cyril Banks shows by a table that Nottingham is well off for hospital facilities. The hospital for mental defectives, however, only provides for female patients, and male patients are accommodated in institutions in various parts of the county. Under the Local Government Act the health committee has been placed in charge of the hospital portion (842 beds) of Bagthorpe Institution. This hospital has been renamed the City Infirmary, but is still a poor-law institution, pending arrangements being made for its separation from the institution and the complete transfer. Until the subject has been more fully discussed the consultation with the representatives of the local voluntary hospitals remains in abeyance. In the meantime a medical superintendent has been appointed and a visiting staff, and every effort is being made to get the best use out of the hospital for the citizens. The new children's hospital, erected on an adjacent site before the boards of guardians relinquished office, was brought into use in the summer of 1930. The damage done by ophthalmia neonatorum was considerable. Of 31 notified cases, 26 were treated at home and 5 in hospital. There were 4 cases of impaired vision and one of total blindness.

An outstanding feature of the year's work was the renovation of insanitary property, made possible by the satisfactory coöperation of owners and agents. The majority of the houses at present being renovated are of the back-to-back type, of which there are nearly 4000, excluding the houses involved in the clearance areas represented during the year. The clearance areas so represented numbered 29, and included 2022 houses, with a population of 7297 persons. This clearance scheme will remove much of the insanitary property, and clear the central portion of the town of slums. Inhabited houses number 71,302, and the corporation own 8367. During 1930 the municipal houses erected numbered 2319. The provision of a public abattoir for Nottingham, says Dr. Banks, is long overdue, and instances are given of the importation of diseased beef into the city. The use of 4 of the 65 private slaughter-houses came to an end during the year.

Difficulties have arisen about the marking of eggs. In some cases the marked area of the shells has been over-stamped with the words "English new laid." In one case proceedings could not be taken, as the underlying marks had been so efficiently removed that the government laboratory was unable to say what the marks had been, and it could not be proved that the eggs were other than English, although the person concerned had been previously convicted for removing marks from imported eggs with acid.

SPECIAL ARTICLES

AN INVESTIGATION OF THE SPECTROPHOTOMETRIC ASPECTS OF THE BENDIEN TEST.

BY FRANK CAMPBELL SMITH, B.Sc. LOND., M.R.C.S.,
FREEDOM RESEARCH FELLOW, LONDON HOSPITAL;

ENSOR ROSLYN HOLIDAY, B.M. OXF., M.R.C.S. ENG.,
OWEN WILLIAMS SCHOLAR, MEDICAL UNIT, LONDON HOSPITAL;

AND

JOHN MARRACK, *D.S.O.*, *M.C.*, M.D. CAMB.,
CHEMICAL PATHOLOGIST, LONDON HOSPITAL.

(From the Hale Clinical Laboratory and Medical Unit, London Hospital.)

IN 1931 Dr. Bendien wrote a book entitled "Spezifische Veränderungen des Blutserums; ein Beitrag zur serologischen Diagnose von Krebs und Tuberkulose."[1] In this book it is not definitely claimed that the alterations found in the serum of carcinomatous patients are of diagnostic value, but a method of examination of serum is described (partly chemical, partly spectrophotometric) which reveals changes said to be characteristic of cancer, tuberculosis, and other diseases. Claims have since been made, on the strength of tests supervised by Dr. Alfred Piney and reported in a statement issued to the press by the general secretary of the British Empire Cancer Campaign, that this method is a diagnostic test for carcinoma, giving positive results even in early cases.

Since the spectrophotometric part of this method is beyond the scope of ordinary laboratory work, involving the use of expensive apparatus and a considerable technical knowledge of physics, and since we have been using this apparatus for some six years, we decided, with the approval of the Medical Research Council, to investigate this aspect of Dr. Bendien's method.

We also had the advantage of the loan from Messrs. Adam Hilger, Ltd., of their most up-to-date form of instrument.

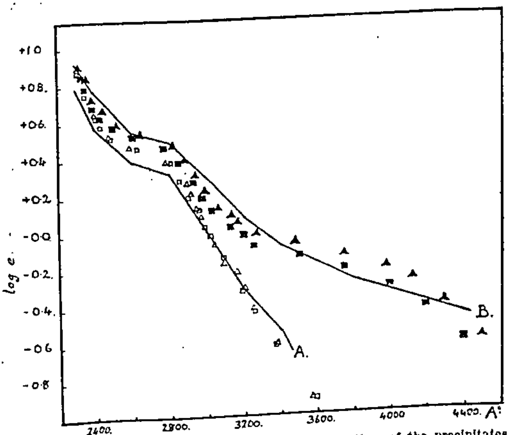
THE CHEMICAL TEST.

The method consists of two parts. In the first, samples of serum are mixed with a series of mixtures containing varying proportions of sodium vanadate and acetic acid numbered 1 to 20. With the sera of healthy persons precipitates should occur only with the mixture numbered 6 and with more alkaline mixtures, while the sera of persons suffering from carcinoma and various other diseases give precipitates with more acid mixtures also. We have performed this part of the method with the sera of 49 persons, including 12 normals and 15 suffering from carcinoma. Of the presumably normal sera only one gave a slight precipitate with mixture 5. All the sera of diseased persons, except one with sarcoma, gave a precipitate with mixture 5. We were not satisfied with the purity of the sodium vanadate used in the first 20 cases. The salt was therefore twice recrystallised. It was then found to contain 9 molecules of water of crystallisation; a decinormal solution contained the theoretical amount of vanadium as estimated by the method given by Treadwell and Hall.[2]

THE SPECTROPHOTOMETRIC TEST.

In the second part of the method, which concerns us more immediately, the precipitate, if any, formed with the mixture 5 is dissolved in sodium bicarbonate solution. The ultra-violet absorption curve of this solution is claimed to have a specific character in cases of carcinoma.

In order to make a so-called 1 per cent. solution of the precipitate for spectrophotometry Bendien filters off this precipitate by suction on a weighed glass filter, continues the suction for a certain time, weighs the filter again and dissolves the precipitate in 2 per cent. NaHCO$_3$, using 10 c.cm. for each 0·1 g. increase in weight. As a matter of fact over 90 per cent. of the increase in weight of the filter is due to retained water, most of which is retained in the disc, and varies greatly with the filter, the strength of suction, amount of precipitate, and temperature and humidity of the atmosphere. Consequently the concentration of the precipitate in the solution so prepared varies considerably. When the logarithm of the extinction coefficient of this so-called 1 per cent.



The effect of standing on the absorption curves of solutions of the precipitates formed with mixture 5. A. Bendien's curve for cancer. B. Bendien's curve for tuberculosis. Solid squares, solution 42 from cancer of breast, examined at once. Open squares, solution 42 from cancer of breast, examined after 36 hours. Solid triangles, solution 44 from rheumatic carditis, examined at once. Open triangles, solution 44 from rheumatic carditis, examined after 36 hours.

---

[1] Bendien, S. G. T.: Spezifische Veränderungen des Blutserums. Jena: Gustav Fischer. 1931.

[2] Treadwell, F. P., and Hall, W. T.: Analytical Chemistry, London, 1924, p. 538.

solution is plotted against wave-length this variation in concentration has the effect of varying the height of the curve, without any variation in the nature of the precipitate; the shape and slope of the curve, however, depend on the nature of the precipitate and not on the concentration. Consequently only the shape and slope of Dr. Bendien's curves are significant; the heights are fortuitous. The curves may be compared by sliding them vertically up or down.

The curves A (cancer) and B (tuberculosis) in the accompanying figure are copied from Bendien's book. Curve A is characterised by a rapid fall of the absorption at 3400 A° and a steep rise (at an angle of about 50° on the scale used by Bendien); while in curve B absorption continues up to 4400 A° in the visible, and the slope is about 35°.

We have followed Bendien's procedure of weighing the moist precipitate and have plotted curves as he does. But we have also estimated nitrogen in the solutions and calculated and plotted the logarithms of the extinction coefficients of solutions containing 0·1 per cent. of protein. In these curves variations in height due to unknown and uncontrolled variations in concentration are avoided. Curves so obtained differ from those obtained by Bendien's method in height but are of the same shape and slope. In the main we shall consider curves based on protein concentration and shall only discuss those obtained after precipitation with the purified vanadate.

We have found that if the spectrophotometric examination of the solutions is done at once the curves obtained both with cancerous and non-cancerous cases resemble B in the figure, with absorption extending into the visible, as might be expected from the yellow colour of the solutions. The points in the figure shown by solid squares and triangles are those so obtained with the solutions from sera of cases of cancer of the breast and rheumatic carditis respectively. If, however, the solutions are allowed to stand they fade slowly and no longer absorb at the longer wave-lengths. The points shown in the figure by open squares and triangles were obtained from the same two solutions after they had stood 36 hours at room temperature partly shaded from light. Thus these two solutions, obtained from cases of cancer and rheumatic carditis, gave when fresh curves "typical of tuberculosis" and, after standing, curves "typical of carcinoma." The changes here shown would be the same if Bendien's method of plotting were used but would be less easy to see owing to differences in height of the curves.

This change was found to occur in every solution which was kept overnight. The change in the absorption curve is accelerated by light and heat. A definite change in two instances was found after standing at 20° C. from 4 P.M. to 7 P.M. on a very dull evening. Presumably yellow hexavanadic acid, formed on acidifying sodium vanadate and carried down with the protein precipitate, slowly changes back to colourless vanadate when made alkaline. The extinction coefficient of sodium vanadate is less than that of vanadic acid; hence the change in the absorption curves. Bendien makes no mention of this change nor of precautions to make sure that it has or has not taken place, such as standing for a given length of time or making immediate measurement. However he does state that "Der flache Verlauf der Kurven (the absorption curves of acidified vanadate solutions) zeigt, dass die Essigsäure-Vanadat-Lösung, die zur Ausflockung gebraucht wird, nicht imstande ist, den Charakter der Absorption der Eiweisslösung zu beeinflussen." Actually the absorption curve of the acidified vanadate solutions are not flat; and if they were they would influence the character of the absorption curves, since it is the logarithm of the absorption coefficient that Bendien plots, and log (a+b) does not equal log a+log b.

CONCLUSION.

We conclude that the absorption curves obtained by Dr. Bendien's method are the same in a variety of diseased conditions, including carcinoma, and that if the absorption is measured at once the curves resemble the tuberculosis curve of Dr. Bendien, changing in process of time to the carcinoma curve.

We feel confident that the spectrophotometric method applied to Dr. Bendien's solutions has no value in the diagnosis of cancer.

Our thanks are due to Messrs. Adam Hilger for the very generous loan of additional spectrophoto apparatus, and also to Messrs. Griffin and T for the loan of a chain balance.

BENDIEN'S WORK ON CANCER.

IN the letter from Dr. A. A. Miller, appearing this title on p. 427 of our last issue, the words "speci stabilisation" should have been printed as " labilisation," while in the sentence "Suspens 20 in all, of various strengths are now submitted to spectrophotometric examination" the word "strengths" should be "thicknesses."

We are informed by Messrs. William Heinemann (Medical Books), Ltd., that they are publishing translation of Dr. Bendien's book on "Specific in the Blood Serum." Dr. A. Piney will be translator.

MEDICAL NEWS

Society of Apothecaries of London.

At recent examinations the following candidates passed in the undermentioned subjects:—

Surgery.—L. F. Donnan, Queen's Univ., Belfast; A. K. Guha, Univ. of Manchester; and J. W. V. Sheldon, Guy's Hosp.

Medicine.—V. R. T. Baylis, Royal Free Hosp.; G. B. Carter, Univ. of Manchester; M. Ditton, Univ. of Heidelberg and Royal Free Hosp.; E. I. B. Hawes, St. George's Hosp.; S. Lokeez, St. Bart.'s Hosp.; L. R. C. Rose, Univ. of Manchester; D. N. Ryalls, Univ. of Sheffield; and E. S. St. John and J. W. V. Sheldon, Guy's Hosp.

Forensic Medicine.—G. B. Carter, Univ. of Manchester; H. W. Davies, St. Mary's Hosp.; B. Dayal, Univ. of Durham; J. M. Durr, Guy's and London Hosp.; S. Lokeez, St. Bart.'s Hosp.; and J. W. V. Sheldon, Guy's Hosp.

Midwifery.—O. A. P. Clark, Westminster Hosp.; J. M. Durr, Guy's and London Hosp.; B. N. Halder, Univ. of Durham; S. E. Paterson, Royal Colleges, Edinburgh; D. N. Ryalls, Univ. of Sheffield; and C. F. Vieyra, St. Mary's Hosp.

The following candidates, having completed the final examination, have been granted the diploma of the Society entitling them to practise medicine, surgery, and midwifery: G. B. Carter, O. A. P. Clark, A. K. Guha, B. N. Halder, E. I. B. Hawes, S. Lokeez, and E. S. St. John.

London Hospital.

The post-graduate course for former students will be held from Wednesday, Oct. 14th, to Saturday, the 17th. Further particulars may be had from Dr. W. Russell Brain, 105, Harley-street, W.1.—The annual dinner of past students will be held at the Trocadero Restaurant, Shaftesbury-avenue, W., on Thursday, Oct. 15th, at 7.30 P.M. The hon. secretaries are Mr. E. C. Lindsay and Mr. G. E. Neligan, 33, Wimpole-street, W. 1.—The annual dinner of the Dental Society will be held at the Trocadero Restaurant on Saturday, Nov. 28th, at 7 P.M. Further particulars may be had from the hon. secretary of the Society, London Hospital Medical College, E. 1.

Paying Patients at Edinburgh.

The corporation of Edinburgh is promoting a Provisional Order which gives power so to alter the charter of the Royal Infirmary as to enable certain patients to be charged a fee for their treatment. The Edinburgh trades and labour council has issued an "open letter" opposing the scheme as "unthinkable," on the grounds that an "absolute discretionary power makes the whole proposition profoundly suspect," and that in view of the fact that there are nearly 3000 names on the waiting-list there ought to be no reduction in the number of free beds.

OBITUARY

ROBERT MacNEIL BUCHANAN, M.B., F.R.F.P.S. Glasg.

Dr. R. M. Buchanan, who died at his home in Glasgow on August 15th after a long illness, was the first city bacteriologist to be appointed by the corporation of Glasgow, and was president of the Royal Faculty of Physicians and Surgeons in 1925.

DR. BUCHANAN.

[Photograph by Lafayette.

Born in 1861, near Drymen, overlooking Loch Lomond, he was the son of John Buchanan, a farmer, and from early environment acquired his bent towards comparative pathology. At first it seemed that this predilection was to be wasted, for after leaving the Glasgow High School he went into business, and rose to be Spanish book-keeper in a well-known firm. But his scientific ambitions remained. He extended his knowledge by attending classes in French, Spanish, and chemistry, and began the study of medicine at the age of 23. During his undergraduate career he attracted the attention of Joseph Coats, who then occupied the chair of pathology, and to whom he ultimately became assistant, and on graduation in 1888 he was awarded the Foulis memorial scholarship, which enabled him to proceed to Germany, where he studied pathology and bacteriology at Frankfort and Berlin under Weigert and Koch. This opportunity determined his future career along congenial lines. Returning from abroad, he delivered a course of University lectures, and about 1892 was appointed the first lecturer on bacteriology to the University of Glasgow, as well as first assistant to the professor of pathology. At this time the important part played by bacteria in the causation of disease was still largely unknown, and the training of a student comprised six lectures on bacteriology. Buchanan combined his pathological work with appointments as physician to the Royal Hospital for Sick Children, and the Western Infirmary, and from 1895 occupied the chair of medical jurisprudence and hygiene in Anderson's Medical College. Here he established the West of Scotland Clinical Research Association, an organisation which still exists, although much of the work it was intended to perform is now carried out in the laboratories of the voluntary hospitals of the city and in those of the corporation.

In 1899 Dr. Buchanan gave up all these posts to become city bacteriologist. He began in a single room fitted up for the purpose, with the use of another room in the tower for the making of media required for the cultivation of bacteria; but the growth of applied bacteriology soon caused the department to assume a more and more prominent place in public health and prevention of disease. One of his first important duties was in connexion with the outbreak of plague in 1900–1901, when he was associated with the professor of pathology in discovering, after long and tedious search, aided by inductive reasoning, the source of plague in the rats which infested a particular area of the city. He himself demonstrated the presence of the plague bacillus in the rat-flea, and was thus able to assist in coping with the spread of the disease. It is recorded that he took the extreme risk of performing the necessary post-mortems without the aid of gloves, which were of so coarse a texture as to hamper the delicate manipulations necessary. Another service was the eradication of glanders from the horses of the tramway department. But these are merely outstanding examples; the laboratory was called upon to deal with many other epidemics, including the outbreak of cerebro-spinal fever in 1906, and nowadays performs a great variety of routine investigations.

One of the chief features of Dr. Buchanan's activities was his interest in comparative pathology. He made it manifest in 1922 that much gain could be expected from the correlation of processes of diseases as they are seen in man and in the lower forms of life. His interests in this respect led him into such questions as the diseases associated with the vegetable and animal world, diseases of great economic importance, such as the blights affecting various fruits, and the diseases of the food-stuffs of our daily consumption—the potato, the currant, the tomato, the apple, and other vegetable products. He also showed for many years a strong liking for the study of insects. This attracted him both for its own sake and because many insects are destructive agents and give rise to serious economic loss. His advice was commonly sought from all over the country with regard to their identification, their habits, and the methods to be adopted for their extermination. For a number of years he had been greatly interested in the causation of grass sickness in horses, because of its similarity to encephalitis in man. The museum which he instituted in the laboratory has proved of great value to sanitarians, and of unfailing interest to visitors from among the general public.

On his election as president of the Royal Faculty of Physicians and Surgeons of Glasgow in 1925, Dr. Buchanan served with distinction for two years, during which he was called upon to organise the celebrations in connexion with the Lister centenary. He retired from the service of the corporation of Glasgow in November of last year. In the words of Dr. A. S. M. Macgregor, to whom we are indebted for many of these details, "his services to the city, his love for his work, and the prominent position he occupied by virtue both of his office and of the universal esteem in which he was held by his fellows, are a measure of the loss which the city has sustained by his death. He was a man of charming personality, and ever willing to assist his younger colleagues."

Dr. Buchanan married the daughter of Mr. John Neilson, Killearn, and she survives him. Their son is a member of the medical profession.

THE LATE GROUP-CAPTAIN MARTIN FLACK.

WE have received from the Air Ministry the following account of Group-Captain Flack's distinguished work in connexion with the Royal Air Force, in supplement to the obituary notice which we published last week:—

"In the early part of the war Group-Captain Flack was lent to the Army, and with Dr. Mervyn Gordon did valuable work in combating the cerebrospinal fever epidemics, and later Sir Walter Fletcher recommended him to the Services Medical Advisory Board to investigate the medical requirements of aviation. As a result he was gazetted as Lieutenant-Colonel, R.A.M.C., and, on the formation of the Royal Air Force Medical Service, as Wing Commander and Director of Medical Research.

"It is no exaggeration to say that the simple system of physiological tests evolved after long practical experiments by Flack has played a fundamental part in aviation medical standards in almost every country to-day. The whole examination of a pilot was expressly designed so that it could be carried out in peace or war with apparatus that an ordinary large suitcase can contain. With sound foresight and judgment Flack decided that the flying personnel should set the standards on which the various grades of pilots were assessed, so he based them on the averaged results of large numbers of pilots sent from their units for examination classed as 'super,' 'average,' and 'borderline,' the absolute rejects being obtained from those who had broken down under the strains imposed by aviation and fighting. These standards and the physiological tests have survived with only very slight modifications to the present day, and have proved their accuracy and worth under varying conditions all over the world. Not only are they of the greatest value in the selection and subsequent care of pilots, both service and civil, but they are the best method which has yet been evolved for detecting what Sir James Mackenzie described as the 'pre-disease state,' and in ordinary life have been utilised for researches into the medical problems of industrial conditions.

"After the war he served as a valuable member of many committees which dealt with aviation and allied subjects, was Milroy Lecturer in 1921, examined at Oxford University, and, in addition to the duties of Director of Medical Research in the Royal Air Force, commanded the Central Medical Establishment. In spite of these many activities, he found time to carry out investigation into the problems of oxygen and high flying, sea and air sickness, comfort in air travel, and other subjects. He was promoted to Group-Captain in 1923.

"The death of Martin Flack has caused an irreparable loss to both service and civil aviation, as there is no one else to replace his unique experience of the medical problems of flying, gained not only from his personal knowledge, but also from the close contact he had maintained from the earliest days with scientists in other countries who were devoting themselves to the same subject."

THE MILROY LECTURES.

Group-Captain Flack's Milroy Lectures, on respiratory efficiency in health and disease, were received by the medical profession as a highly valuable contribution to physiological knowledge on a subject of great practical importance. He raised the whole question of physical efficiency tests, and the value of special physical training, his views resulting from investigations undertaken in the course of his duties in connexion with the Royal Air Force Medical Service. His observations were pertinent, also, to the question of the comparative value of gymnastic exercises and outdoor games, and went to prove that success in respiratory tests connotes general good health, while failure to reach certain standards may imply unfitness. The lecturer described the system of routine tests for vital capacity and endurance which he had followed in arriving at his conclusions, and detailed a system of ten exercises aimed to develop circulatory and respiratory efficiency, an instructor attending the delivery of this part of the lectures in order to demonstrate the technique. The lectures were published in full in THE LANCET (vol. ii., 1921, pp. 593, 637, 693, 741).

ALBERT ALFRED TINDALL,

PROPRIETOR OF "THE MEDICAL PRESS AND CIRCULAR."

THE death on August 21st is announced of Mr. Albert Alfred Tindall, sen., principal of the firm of Baillière, Tindall and Cox, the well-known and long-established publishers.

Albert Tindall was born on Nov. 21st, 1840, being at the time of his death well advanced in his 91st year. He was the son of Mr. S. Tindall, of Brede, near Hastings, was educated privately, and came to London as a commercial clerk. He got an introduction to the well-known ophthalmologist, Dr. Archibald Jacob, of Dublin, who was the proprietor of the *Medical Press*, which then circulated largely in Ireland, and of an English medical journal, *The Medical Circular*. In the meantime Tindall had become the proprietor of a publishing business, and in 1866 he took over the publication of Dr. Jacob's two weekly papers, amalgamating them under the title of *The Medical Press and Circular*. Of this journal he eventually became the sole proprietor, and his general management of it was continued without a break till the commencement of his short and final illness—a period of no less than 65 years. The firm of Baillière, Tindall and Cox was founded by Tindall in 1870, having its origin in the union of a branch of the well-known firm of Baillière et Cie, in Paris, with the firm of Tindall and Cox, and of this business Albert Tindall became the enterprising head, and the list of its publications speaks for its standards and progress. For some time now his son, Mr. A. A. Tindall, jun., has had the reins of government, though the father supervised the issue of *The Medical Press and Circular*.

During his long life Albert Tindall became well known personally to a very large number of people, and in the district where his business lay his was a familiar figure, his upright carriage and alert movements giving a flattering denial to his real age. He had for many years been deaf, but though cut off in this way from much social intercourse, he kept in close touch with personal friends, and his loss will be widely felt.

Mr. Albert Tindall was twice married. He married first, in 1873, a daughter of the late Mr. J. S. Simson, of Deptford, a timber merchant and director of the Surrey Commercial Docks, and secondly, in 1890, a daughter of Sir William Bower-Smythe, of Hill Hall, Essex. He leaves a widow, one son, Mr. A. A. Tindall, jun., and three daughters. A younger son was killed in the war, while the eldest daughter is the wife of Dr. Arthur Giles, the well-known obstetrician.

MR. CHARLES RICHARD HEWITT, who died last week in a nursing home at Ealing, at the age of 61, was well known in London as a medical librarian. After 22 years service he became in 1907 joint librarian of the Royal Society of Medicine, taking a large part in the rearrangement of the several libraries of the amalgamated institutions. In 1919 he accepted an invitation from the League of Red Cross Societies to organise a public health library and registry at Geneva, and two years later he undertook for Messrs. William Heinemann, Ltd., the compilation of the *Medical Year Book*. Since 1925 he had been chief librarian of the research library which forms part of the Wellcome Historical Medical Museum. At different times he undertook responsibility for the medical libraries at University College and Guy's Hospital, and supplied the Royal Commission on Tuberculosis with references to all the periodical literature on a vast subject. Personal contact with most of the distinguished physicians and surgeons of his day qualified him to contribute a number of biographies to "Men and Women of the Time" and contemporary journals.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ST. MARK'S HOSPITAL, City-road, E.C.

THURSDAY, Sept. 3rd.—4.30 P.M., Dr. J. K. Hasler: Spinal Anæsthesia.

Appointments

DAVIDSON, J. F., M.B., Ch.B. Aberd., D.P.H., has been appointed County M.O.H. and School M.O.H. for West Suffolk.

JONES, A. T., L.R.C.P. Lond., M.R.C.S., Certifying Surgeon under the Factory Acts for Carmarthen.

Vacancies

For further information refer to the Advertisement columns.

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

Altrincham, General Hospital.—Jun. H.S. At rate of £120.

Ashton-under-Lyne District Infirmary.—Res. Surg. O. £200.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £175.

Beckenham, Kent, Bethlem Hospital, Eden Park.—Locum Tenens M.O. 7 gns. per week.

Bedford County Hospital.—Asst. H.S. At rate of £130.

Birmigham and Midland Eye Hospital, Church-street.—H.S. £110.

Blackburn County Borough.—Asst. School M.O., &c. £600.

Bootle General Hospital, near Liverpool.—Cas. O. and two H.S.'s. All at rate of £150.

Brighton, New Sussex Hospital for Women and Children.—H.P. At rate of £100. Also Hon. Asst. Ophth. Surg.

Bristol City and County Mental Hospital.—Fourth Asst. M.O. £350.

Bristol Eye Hospital.—Anæsthetist. Also Res. H.S. £150.

Bristol Royal Infirmary.—H.P. £60.

Carnarvonshire C. C.—Deputy M.O.H. and Asst. School M.O. £700.

Cambridge, Addenbrooke's Hospital.—Two H.S.'s. Also Res. Anæsthetist and Emergency Officer. All at rate of £130.

Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.

Cardiff Royal Infirmary.—H.P. and H.S. Each at rate of £50.

Connaught Hospital, Walthamstow, E.—Sen. Res. H.S. At rate of £150.

Coventry and Warwickshire Hospital.—Two Res. H.S.'s. Each £125.

Croydon General Hospital.—Hon. Surgeon for Ear, Nose, and Throat Dept.

Cumberland, Blencathra Sanatorium.—Asst. to Med. Supt. £300.

Derby, Derbyshire Royal Infirmary.—Ophth. H.S. £150.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Dudley, Guest Hospital.—H.S. £170–£200.

East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. At rate of £150. Also H.S. to Special Depts. and Cas. O. Each at rate of £120.

Edinburgh Royal Infirmary.—Clin. Assts. for Ear, Nose and Throat Department.

Great Yarmouth General Hospital.—H.S. £140.

Harrogate General Hospital.—H.P. At rate of £150.

Harrogate Infirmary.—Jun. H.S. At rate of £125.

Harrow-on-the-Hill, Harrow and Wealdstone Hospital.—Res. M.O. At rate of 140 gns.

Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—H.P. At rate of £150.

Hove, Lady Chichester Hospital.—Jun. H.P. At rate of £50.

Hull, Corporation of Kingston-upon-Hull and Hull and Goole Port Sanitary Authority.—Asst. M.O.H. £600.

Hull Royal Infirmary.—Third H.S. for Parent Institution. £150. Also H.P. Sutton Branch Hospital. £160.

Leeds City.—Chief Asst. M.O.H. £900.

Leicester Royal Infirmary.—H.P. and H.S.'s. Also Cas. H.S. All £125.

Liverpool Eye and Ear Infirmary, Myrtle-street.—H.S. to Ophth. Dept. £120.

Liverpool Open Air Hospital for Children, Leasowe.—Jun. Res. M.O. £200.

London Temperance Hospital, Hampstead-road, N.W.—H.P. At rate of £100.

Maidstone, Kent County Ophthalmic and Aural Hospital.—H.S. At rate of £200.

Manchester, Northern Hospital for Women and Children.—Sen. H.S. and Jun. H.S. £130 and £100 respectively.

Manchester Royal Children's Hospital, Pendlebury.—Two Asst. M.O.'s for Out-patients' Dept. Each at rate of £150. Also Res. M.O. At rate of £125.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester Royal Infirmary.—Technical Asst. for Clinical Lab. Work. £200.

Manchester and Salford Hospital for Skin Diseases.—H.S. At rate of £100.

Margate Royal Sea Bathing Hospital for Surgical Tuberculosis.—H.S. At rate of £200.

Middlesex Hospital, W.—Dental H.S. At rate of £200.

Miller General Hospital, Greenwich, S.E.—Cas. O. At rate of £150. Also H.P. At rate of £125.

National Hospital for Diseases of the Heart, Westmoreland-street, Marylebone, N.W.—Res. M.O. Also Out-patient M.O. At rate of £150 and £125 respectively.

Newcastle-upon-Tyne, Hospital for Sick Children.—H.P. and Sen. and Jun. H.S.'s. All at rate of £100.

Northampton General Hospital.—H.P. and Four H.S.'s. Each at rate of £150. Also Res. Dresser. £10 for six months.

Norwich, Norfolk and Norwich Hospital.—H.S. and H.P. Each at the rate of £120.

Nottingham General Dispensary, Broad-street.—Res. Surg. £250.

Oldham, Boundary Park Municipal Hospital.—Res. Asst. M.O. £200.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, Kensington, W.—H.P. At rate of £100.

Queen's Hospital for Children, Hackney-road, E.—Asst. Surgeon.

Richmond Royal Hospital, Surrey.—Jun. H.S. At rate of £100.

Rochester, St. Bartholomew's Hospital.—H.P. At rate of £175.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Two H.S.'s Each at rate of £150. Also H.S. for County Branch, Brockley Hill, Stanmore. At rate of £150.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. Clin. Asst.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—H.S. At rate of £75.

Salford City Education Committee.—Asst. School M.O. £520.

Salisbury, General Infirmary.—H.P. £150.

Sheffield Royal Hospital.—Ophth. H.S. Also Anæsthetist. £120 and £80 respectively.

Sheffield Royal Infirmary.—Asst. Aural and Ophth. H.S. and H.S. and Second Asst. Cas. O. Each at rate of £80.

Shrewsbury, Royal Salop Infirmary.—Cas. O. and Res. Anæsthetist. At rate of £160.

Sidcup, Kent, Queen Mary's Hospital.—Asst. M.O. £250.

Southampton, Children's Hospital and Dispensary for Women.—Res. M.O. At rate of £100.

South Eastern Hospital for Children, Sydenham, S.E.—Asst. Res. M.O. At rate of £100.

Stafford, Staffordshire General Infirmary.—H.S. £200.

Stockport Infirmary.—H.P. £175.

Swansea General and Eye Hospital.—H.P. £150.

Taunton and Somerset Hospital.—Sen. H.S. £150.

Torquay, Torbay Hospital.—H.P. and H.S. Each £175.

Wakefield, Clayton Hospital.—H.S. At rate of £200.

West Bromwich and District General Hospital.—H.P. At rate of £200.

West London Hospital, Hammersmith-road, W.—Res. Asst. S. £200. Also H.P., H.S.'s, and Res. Anæsthetist. All at rate of £100.

Weston-super-Mare General Hospital.—Res. H.S. £150.

Wigan, Royal Albert Edward Infirmary and Dispensary.—H.S. At rate of £150.

Winchester, Royal Hampshire County Hospital.—H.S. At rate of £100.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

York, City Mental Hospital, Fulford.—Asst. M.O. £500.

Births, Marriages, and Deaths

BIRTHS.

HUME.—On August 20th, 1931, at Wildwood-road, N.W., to Marjorie, the wife of J. Basil Hume, M.S., F.R.C.S.—a daughter (Gillian Mary).

LANDER.—On August 20th, at Salisbury-terrace, Devonport, the wife of O. Ll. Lander, M.R.C.S., L.R.C.P., of a son.

DEATHS.

HALES.—On August 20th, at Holt, Norfolk, Robert Turner Hales, M.D., aged 77 years.

LISTER.—Suddenly on August 18th, at his residence, Almeston-road, Bath, Herbert Shaw Lister, M.B., Ch.B. Vict., M.R.C.S. Eng., L.R.C.P. Lond., beloved husband of Elizabeth Lister, aged 55 years.

STEVENSON.—On August 19th, at Temple Sowerby, Louis Edgar Stevenson, B.A., M.B., B.C. Camb., aged 68 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births Marriages and Deaths.

EXTENSION OF YOKER HOSPITAL.—On the recommendation of the Renfrew and Clydebank joint hospital board, the Clydebank town council has decided considerably to enlarge the Blawarthill Hospital at Yoker. The plans include the provision of a new nurses' home, two wards of 24 beds, an observation ward of 16 beds, and a theatre. The cost, exclusive of alterations to the existing administration blocks, will be £57,000.

MOTOR ACCIDENT CASES AT ADDENBROOKE'S HOSPITAL.—During the second quarter of the present year Addenbrooke's Hospital, Cambridge, received 52 persons injured by motor vehicles, of whom 23 were admitted to the wards. Two died within 24 hours, 15 were discharged after treatment, and six remained at the end of the quarter. The number of bed-days occupied was 326, and the estimated cost £133, towards which one donation of two guineas was received.

NOTES, COMMENTS, AND ABSTRACTS

FACTORY GIRLS' HOLIDAYS.

THE following letter reaches us from the Factory Girls' Country Holiday Fund:—

"At this time, when 'all the world' (as we say) is making holiday or preparing to do so, we hope that that they will spare something for that considerable remainder which cannot afford a holiday, or not on a sufficient scale. In particular, we ask them to remember once more, as they have in former years, the Factory Girls' Country Holiday Fund. Last year this fund arranged 1250 weeks of holiday for 1030 women and girls at a cost, including travelling, of £1630, of which sum more than one-third was contributed by the holiday-makers themselves. We would call special attention to this last point. Those who give to this fund have assurance, not merely that the money they give will be well spent, but also that it will encourage the wise spending of much other money, the hard-earned savings of the girls themselves, so that every pound they give will in effect provide a full week's holiday for a working woman. This is surely a good investment from a strictly financial point of view; and if anyone has other doubts, these can soon be settled by a visit to headquarters during the holiday season. The eager and excited crowds alone will tell him much, and a comparison between the group that is ready to go off and the group that has just come back will tell him the rest. Lastly, the subscriber may be assured that the fund is in the hands of careful and competent administrators, who make every effort to secure that girls are helped only so far as they cannot help themselves—and that they are encouraged throughout the year, by means of saving-cards and in other ways, to make the most of their ability to help themselves. Even in these difficult times we hope that support will be forthcoming generously and promptly for this work. Subscriptions and donations will be thankfully received and acknowledged by the hon. treasurer, Mrs. Slater, or Miss Mary Canney, 75, Lamb's Conduit-street, London, W.C.1."

The appeal is signed by the Countess of Sandwich, Mrs. Creighton, Miss Lilian Braithwaite, Dr. Octavia Lewin, the Very Rev. J. H. Hertz (Chief Rabbi), Prof. J. L. Stocks, Mr. J. F. Green (Chairman of Executive), and Mrs. Slater.

METHYLATED SPIRIT DRINKING.

THE Commissioner of Police of the Metropolis, in his report for 1930, records a decrease in convictions for drunkenness attributable to the drinking of methylated spirits; the convictions numbered 32 (27 males and 5 females), as against 45 in the previous year. On the other hand, the Licensing Statistics for the whole of England and Wales, recently published by the Home Office (Cmd. 3928, price 3*s.*) show an increase of 16·38 per cent. in 1930; the total was 476 (336 males and 140 females), against 409 (288 males and 121 females) in the previous year. Figures of these convictions have been collected for England and Wales since 1920; the annual average since then is 463. Details of the geographical distribution of the convictions show that methylated spirit drinking is widely scattered. Liverpool heads the list with an outstanding total of 74—more than double the total for the metropolitan area. Cardiff has 23, Hull and Manchester 14 each, Leeds 13, and Birmingham 10. Normally, as the gross totals indicate, the convictions of men substantially outnumber those of women. Yet at Liverpool 64 women are convicted, as against 10 men, and at Manchester 10 women, as against 4 men. Study of the detailed figures produces rather surprising results. We find 23 cases at Cardiff, but only one at Swansea, nine in the small borough of Caernarvon, but only three at Plymouth or Sunderland, and only two at Portsmouth or Southampton. Winchester and Henley-on-Thames are found on the same mark as Plymouth; Exeter, Cheltenham, and Bury St. Edmunds on the same mark as Portsmouth. Although at Trowbridge, in Wiltshire, three out of the four convictions for drunkenness in 1930 are ascribed to methylated spirit drinking, it is proper to remember—as the introduction to the Licensing Statistics points out—that the total of convictions attributable to methylated spirits continues to be trifling as compared with the total of convictions for drunkenness. The latter figure amounted to 53,080 in 1930, as compared with 51,966 for 1929. The increase (2·14 per cent.) is small, but this is the first time since 1924 that the total has shown an increase.

PRIMARY CARCINOMA OF FALLOPIAN TUBE.

J. Rabinovitch and J. D. Horton, who report a case[1] under their observation at the Missouri Baptist Hospital, remark that primary growths of the Fallopian tube are not very common, and owing to their great similarity to other pelvic conditions are seldom recognised before operation and examination of the specimen. The condition is usually seen in persons at or past the menopause and its true nature is apt to be mistaken owing to the frequency of secondary inflammatory changes. The commonest symptoms are watery or sero-sanguineous vaginal discharge, with or without abdominal pain. Both the pain and the discharge may vary in character and severity in different people or in the same person at different times. According to the size and position of the tumour in the pelvis there may be urinary or intestinal disturbances, such as frequent or urgent micturition or constipation. Marked loss of weight and cachexia are seldom observed, but under-nourishment and anæmia are not unusual. The size of the tumour varies from that of the little finger to that of a large mass filling the abdomen. The growth is fixed or freely movable according to the amount of inflammatory changes. The middle or distal third of the tube is the commonest site for the tumour, which may be unilateral or bilateral. The commonest histological varieties are the papillary and papillary alveolar, various modifications of these two patterns being encountered in different tumours.

Rabinovitch and Horton's case was in a woman, aged 55, who had reached the menopause five years previously. For the last two years she had had a watery vaginal discharge which had become more profuse and continuous during the past five months and had become sanguineous during the last three weeks. The uterus was small and retroverted and the adnexa were not palpable. A diagnosis of malignant disease of the uterus was made and laparotomy performed. The uterus, ovaries, and right Fallopian tube appeared normal, but the left tube was enlarged at its distal end. Although its gross appearance was indistinguishable from a chronic inflammatory process, the limitation of the lesion to one portion of the tube suggested malignancy and panhysterectomy was performed. No histological abnormalities were found in the uterus, ovaries, or right Fallopian tube, but sections of the left tube showed the appearance of a papillary carcinoma.

The issue of the case is not recorded.

NEW SKIPTON HOSPITAL.—Last week six foundation-stones of the new Skipton and District Hospital at Whinfield were laid by people closely connected with hospital work in the district. The buildings, which will cost over £13,000, will be opened free of debt, and there is an endowment fund of about £12,000.

FOREIGN DECORATIONS.—The King has given to the undermentioned gentlemen licence and authority to wear the decorations mentioned: to Dr. Theodore Dyke Acland (a British Official in the service of the Soudan Government) and Dr. Douglas Erith Derry the insignia of the second class of the Order of the Nile, and to Dr. Salvator Michael Vassalo the insignia of the fourth class of the Order of the Brilliant Star of Zanzibar, which Orders have been conferred by the King of Egypt and the Sultan of Zanzibar respectively in recognition of valuable services rendered by them.

ADDRESSES AND ORIGINAL ARTICLES

THE MECHANISM OF INFLATION OF THE LUNGS

AND THE INFLUENCE OF DEFLATION ON POST-OPERATION COMPLICATIONS.

BY SIR CHARLTON BRISCOE, BT., M.D., F.R.C.P. LOND.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL.

IN the past three years a number of papers have appeared dealing with post-operative collapse of the lung, but the reader will find no agreed opinion about the production of this condition or the manner in which it should be treated. Nor does it appear to me that there is any clear distinction of the various conditions which are found and which have been called collapse. At least four have been included under this term, namely :—

(1) A condition in which the lower part of the lung is more or less airless, but in which there may be no symptoms. This may be called *simple deflation.*

(2) Simple deflation in which there is clearly a bronchial irritation varying in degree, with consequent mucous or muco-purulent secretion : *simple deflation with secretion.*

(3) The condition which originally attracted Pasteur's[1] attention, in which, sometimes without but generally with a very acute onset, one or both lower lobes of the lungs are found to be airless, the heart being displaced to the affected side. Purulent secretion may or may not develop : *massive collapse attack.*

(4) A condition of deflation of the whole of one lung, most commonly found in injuries (often trivial) of the chest, and not necessarily or usually as a post-operative complication. This has been fully described by Rose Bradford[2] from his experience in France during the war, and may be termed *massive deflation of one lung.*

The types of simple deflation are very common, but they have been neglected, attention having centred on the two rare conditions and their possible explanation. I hope to show that simple deflation is not merely very frequent but that it is essential that it should be studied and understood before speculation is indulged in concerning the nature of the more rare massive collapse attacks or deflation conditions.

BASIC ANATOMICAL AND PHYSIOLOGICAL FACTS.

There are two normal anatomical and physiological facts which must be kept persistently in mind, since they are constant influences in the production of deflation.

(1) *Elasticity of lung.*—Throughout the whole of life, after the first few breaths, the lungs never cease to try to contract down to an airless condition. They are prevented from doing so by the facts that they are enclosed in the thoracic cage, and that nature abhors a vacuum. The cage, however, nowhere quite rigid, shows different degrees of mobility in different parts, and such mobility is affected in various ways by different conditions. To put it another way: the lungs always deflate as much as they are allowed to, but this allowance is subject to very wide variations.

(2) *Minimal use at rest.*—Man is endowed with much more respiratory air space than he requires when at rest. This well-known and obvious fact, akin to the reserve power of the heart, has not been sufficiently stressed ; to all intents and purposes it has been ignored. This is accounted for by the fact that deflation has only been discovered when some pathological condition has necessitated examination, and hence a pathological condition has promptly been invoked as the cause of the deflation. The true sequence in these cases is that deflation ensues as a simple consequence of rest in bed.

As illustrating this point, the following three papers are of importance. My colleague, Dr. J. L. Livingstone,[3] has shown that, when changing from upright to supine, the volume of the chest, as measured by the excess of air exhaled, is reduced by about 500 to 1000 c.cm.—10 per cent. to 20 per cent. of the total volume of the lungs—and that in the intermediate position of reclining at an angle of 45° the diminution is proportional—i.e., about one-half. This reduction occurs within ten breaths. W. H. Wilson[4] has shown in a similar manner that the reserve air is reduced under similar circumstances by about 1200 c.cm. His observations were made two minutes after the change from the erect to the supine. These two observations were made on normal individuals.

J. R. Head[5] has shown that the vital capacity of the thorax is markedly diminished—from 8 per cent. to 80 per cent.—when tested during a period of from 2 to 18 days after operations, such as those on the abdomen, for removal of the breast, and for the treatment of hæmorrhoids. The value of this paper would be enhanced if the author could have recorded the diminution in the vital capacity of individuals who were rested in bed without operation—i.e., if he could have tested what occurs in the normal.

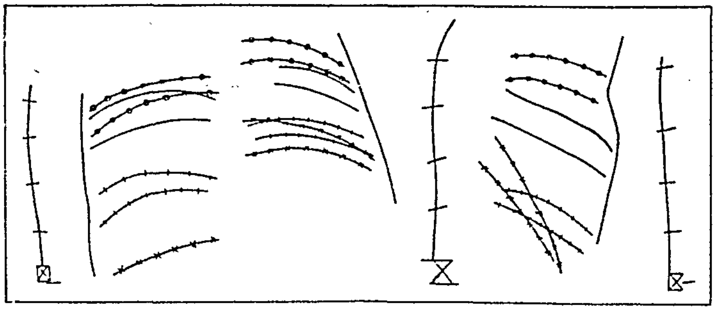
These three investigations show beyond doubt that under the circumstances in which the observations were made a considerable reduction in the volume of the thorax takes place. Livingstone's observations were made, so far as possible, with involuntary or unconscious—as opposed to forced—respiration ; the other two observations were made with forced, and therefore conscious, expiration ; they are of less value when applied to the usual and unconscious respiration, but are confirmatory of that change which Livingstone records in the normal individual. From these three papers, however, a logical deduction can be made : that on assuming the supine posture a diminution in the intrathoracic volume takes place immediately, and that such diminution is not limited to the first ten breaths but is continued for some time. In these circumstances the volume of the lung is decreased. Such a diminution might occur equally in both upper and lower lobes, or by a diminution in either one or the other. Further, such a marked diminution in the size of one lobe, either the upper or the lower, might occur as would necessitate an over-inflation of the alternate lobe.

The thoracic cage is a complicated structure of bone and muscle. In the past an attempt was made experimentally to gain an insight into its movements by reproducing the effect of maximal contractions of the muscles. In life, however—except perhaps in yawning, sighing, and asphyxia—such maximal contractions are not evoked ; the usual nerve impulses are not strong enough to produce them. At rest the weaker stimuli conditioned by diminished respiratory requirements evoke a smaller thoracic expansion. This diminished expansion is not the result of a general decrease of contraction of each muscle concerned. A process of selection occurs to determine which muscle or part of muscle shall respond to the weaker nerve impulse. In this selection or grading the condition of stretch of the muscle plays an important rôle. Hence the expansion of parts of the thoracic cage is unequal, and the diminution of lung volume and deflation which occurs at rest is by no means equal in all directions, but occurs in special parts in a special manner which I shall explain. Accordingly, an inquiry into the mode of respiration in circumstances where deflation is found will throw light on the mechanism of expansion of the different parts of the lung.

Although it is always desirable that pathological findings should not be taken into consideration before establishing a normal, yet this is almost impossible in the present investigation. I have, however, tried to base the conclusions upon those conditions which most nearly represent experimental findings.

Following the line of investigation in the normal individual assuming the supine posture with quiet breathing, two important points emerge—viz., an immediate change occurs in both diaphragm and thorax.

(1) The diaphragm is elevated.[6] The usual X ray inspection (tube behind and screen in front) demonstrates this point. Especially is this seen in the mid-axillary region, but mesially to the nipple lines the elevation is less marked. This view does not give a complete picture of what happens. By the employment of tangential views occurrences immediately below the surface of the ribs at any given points can be investigated, and the height (of the point) at which the diaphragm leaves the chest wall above the costal margin—the upper level of the costophrenic sinus—can be measured. By this means it is seen that an immediate rise occurs in the level of the costal diaphragm, particularly at its posterior part, in the scapular line, averaging 4 cm. on the right and 4·5 cm. on the left. The rise is much less—2 cm.—in the nipple line. There is, therefore, when assuming the supine posture, a general rise in the level of the costal diaphragm, and this is more marked in the postero-lateral than in the anterior regions. This elevation is least marked in the antero-posterior mesial area, the plane of the crus. At the same time the natural inspiratory descent continues, although it may be diminished. Pasteur [1] has shown that this diminution of the diaphragm movement persists some days after operation.



X ray examination (tangential), showing the points at which the diaphragm leaves the chest wall in different postures. The left figure records that point in the post-scapular line on the right side. The figure to the right illustrates the same in the left post-scapular line. The central figure illustrates the points in the right nipple line. In each instance: (1) The line with circle equals supine. (2) The straight line equals reclining at an angle of 45°. (3) The line with single dash equals standing. (4) The line with stars equals knee-elbow position. Where the lines are in pairs the top one is expiration, the lower one inspiration. Where it is single the position in both phases is constant.

The cross is placed on the lowest rib in the line under investigation. Vertical cross bars placed at inch intervals lie on outer surface of chest wall. Other vertical line represents pleural surface of chest wall. Subject, a healthy medical student, aged 23. Quiet involuntary respiration throughout.

(2) In the thorax the transverse diameters (at the three levels of the manubrium, gladiolus, and lower costal margin) and the antero-posterior diameter (at the first two levels) show increases.[6] The changes in the diameters of the upper part of the thorax attain their maximum in a few hours, but the transverse diameter at the level of the lowest rib continues to increase during several days (in post-operative cases), and probably the diaphragm continues to rise progressively with this change.

When assuming the supine posture, therefore, the transverse and antero-posterior dimensions of the upper part of the thoracic cavity are increased, while the vertical measurement is diminished. The net result of this change of posture—a diminution of capacity—occurs at the expense of the lower part of the thoracic cavity, and more at the back than anteriorly.

We should anticipate that the lower lobe would become de-aerated, "deflated," and the upper lobe would remain aerated or even hyperinflated *as long as the conditions of quiescence and recumbent posture persist.* Under such circumstances we do, in fact, find deflation of the lower lobes.

Deflation cannot be detected in the course of a few seconds—i.e., not as quickly as the changes in the diameters of the chest wall or the elevation of the diaphragm. It is marked in 36 hours.

Physical Signs.

Deflation of the lower lobe in varying degree is very common. It is not detected because, in the routine examination, the first few voluntary breaths taken by the patient obliterate the signs, and the front of the chest is examined fully before that of the back is commenced. It is when the patient does not, or cannot, take the deep breaths that the signs are detected. If, however, a rule is made to percuss and auscultate the back before asking for a deep breath, signs are readily detected. The signs will be found fully developed at the end of 36 hours, or less, in any adult patient who lies quiescent, and, therefore, regularly and typically for the first few days after operation.

As the lower lobe deflates, the anterior and inferior margins retreat, the base rising, and when deflation is complete the lobe occupies an area beneath triangular space delineated by: (*a*) the middle-lin spines of the vertebræ, (*b*) a *horizontal* line throug the eighth rib in the scapular line, and (*c*) an obliqu upper margin from the fifth dorsal vertebra to th horizontal line (*b*) as this cuts the posterior axillar line. This is the area where the signs are detecte Over a lobe partially deflated there are to be ma out:—

(1) Diminished resonance to percussion.

(2) Diminished air entry on inspiration, tub breathing, and sometimes crepitations.

(3) Increased voice sounds, and increased ta vocal fremitus.

These are the signs of a lung of which the de is increased, in this case by deflation. Where deflation is early the signs are less marked and crepitations occur with inspiration. As the lower lobe deflates more completely and shrinks towards the root of the lung and away from the chest wall, the air entry is less audible and voice sounds remain increased and bronchophonic. The triangular area contracts as the upper lobe becomes over-expanded and encroaches on it.

The diaphragm being elevated as a whole (back, front, and sides, the mesial portion least), the organs in relation to it are elevated with it. The absolute dulness below the eighth rib posteriorly is due to the elevation of the diaphragm and underlying organs. The liver dulness on the right side anteriorly is also elevated as high as the fifth rib or fourth space, and resonance from the abdominal organs may replace the lower area of normal liver dulness. On the left side the apex beat is elevated and rotated outwards so as to be behind the fifth rib or in the fourth space. The stomach resonance is high in the axilla.

When a deep diaphragmatic breath is taken, protruding the abdomen, these signs become less marked and, with repetition, disappear with a shower of crepitations, only to return with renewed quiescence. Those normal individuals with (*a*) big respiratory capacity, (*b*) a natural tendency to thoracic breathing, (*c*) signs of emotional distress, (*d*) loss of muscular control of the lower thoracic margin, (*e*) evidence of general debility, and (*f*) those who remain in such a posture that the spine is extended, tend to breathe with the upper thorax at the expense of the diaphragm and so to develop deflation of lower lobes the more readily.

The two first conditions are relatively commoner in the young, and in them deflation occurs the more readily. Collapse attacks of extreme severity are many times more frequent in the young than the old.

Pathological Evidence.

(1) *Simple picture.*—This appearance of simple deflation of the lungs has escaped attention, largely owing to the fact that in a routine post mortem we do not obstruct the trachea before opening the thoracic cavity. In consequence air escapes from the lungs and ante-mortem deflation is less noticeable. When the trachea is properly blocked—as by ligature over a cork inserted through a tracheotomy incision—the relative size of the lobes is readily noticed.

The simple picture is as follows: the deflated area is smaller than normal, darker in colour, and more solid to the touch, and the capsule is wrinkled. It contains little air, and therefore tends to sink in water. Microscopically, the walls of the air vesicles are approximated, blood-vessels are dilated, and fibrous tissue is distended and more obvious than usual. The fibrous tissue has to stretch to follow the shrinkage due to deflation. The walls of smaller bronchioles are sometimes as much approximated as those of the still finer portions of the lungs. The larger bronchial tubes are patent, and may or may not contain some mucus and cells. In a simple case there is no evidence of pleurisy or of inflammatory action in the lung or of desquamation of bronchial mucous membrane. The condition may be found affecting parts of the lower lobes in different areas and degrees; it is not of necessity limited to the lower lobe. The posterior part of the upper lobe may be deflated. All stages of incomplete deflation may naturally be found, and differences in the march or mode of the deflation of the two lungs are detectable.

This is the condition which is obviously present during life in many of our "bed patients" in greater or lesser degree. Ante-mortem œdema obliterates the evidence and, naturally, apart from œdema, the whole picture is frequently modified by the existence of injury or disease. A careful study of selected instances will help to illustrate. Such instances arise when death has occurred suddenly and without struggle, or when terminal œdema has not occurred in those who have lain quiescent prior to death.

The simplest condition may be best seen under the following circumstances, many examples of which have been observed and studied:—

(*a*) *Coma cases,* in those who have been unconscious and have lain still for hours or days prior to death as in cases of cerebral tumour. During life recumbency has been absolute, and there has been no forced breathing. In these there has been no impediment to the diaphragm or to the chest wall. There has been increased respiratory movement of the upper chest, and diminished abdominal protrusion. The movement of the epigastrium may even be reversed—inspiratory recession. By X ray the diaphragm is seen to be high and to descend in inspiration. The lower lobes are found post mortem in the condition described above. There is no obstruction to the bronchial tree.

(*b*) *Operation cases.*—During the first few days after operation, especially if there has been an incision through the abdominal wall, the patient is exhausted and movement painful. The epigastrium is found to protrude to some extent in inspiration, showing clearly that the diaphragm is not paralysed. The upper thorax is hyperactive in inspiration. The diaphragm is high, but inspiratory descent, though present, is diminished. When cases of this nature die suddenly and unexpectedly within the first few days after operation, as from pulmonary embolus, there will be found marked deflation of the lower lobes, with hyperinflation of the upper lobes. There is no obstruction to the bronchi.

(*c*) *Spinal cord lesions.*—In conditions of spinal cord obstruction in the upper dorsal or lower cervical region the patient is most comfortable when propped up, for gravity helps to counteract the notable elevation of the thorax by the scalene in inspiration and thus assists expiration. The intercostal and abdominal muscles are paralysed. The diaphragm can be seen by X ray to be at a remarkably high level and moving with inspiratory and expiratory excursion. (By volitional effort it can be temporarily depressed to a greater degree than is otherwise seen.) The lower lobes are more completely deflated than in any other condition. Sometimes the deflation extends to the back part of the upper lobes. The upper lobes are markedly over-distended. In cases of some weeks' or months' standing the bronchi contain a little material which, on investigation, is found to consist of cells from which the nuclei have mainly disappeared, and a small amount of mucus. There is *no obstruction* to the bronchi. The physical signs of deflation of the lower lobes are readily detected in such cases.

(*d*) *Unilateral phrenic paralysis.*[7]—In conditions in which one phrenic nerve is blocked by pressure, as from glands in the neck, thus throwing out of *action* half the diaphragm, the movement of the chest wall is not impeded, but may be increased. The unaffected portion of diaphragm contracts normally; the paralysed half is somewhat elevated and has a paradoxical action. The lungs show (*a*) a considerable degree of deflation of the lower lobe on the affected side, (*b*) a fully inflated lower lobe on the sound side, (*c*) a considerable degree of deflation of the upper lobes, more on the affected than on the unaffected side. There is no obstruction to the bronchi of either the lower or the upper lobes.

The above four instances, being concerned with normal lung, are examples almost experimentally ideal. They show that under conditions of respiratory activity reduced to the minimum by posture or weakness, a defect of expansion of the lower lobe occurs. When correlated one constant factor emerges: the lateral part of the diaphragm beneath the deflated lower lobe or lobes is elevated. The condition of the chest wall varies, as does the inspiratory descent of the diaphragm. We are led to the conclusion that expansion of the lower lobe requires a combination of two factors: (1) a low, and (2) a contracting diaphragm. Applying the same interpretations, the degree of inflation of the upper lobe is dependent (1) upon the maintenance of a condition of postural tonus in the whole diaphragm (as opposed to paralytic tonelessness in part); and (2) upon activity of the upper chest. This latter deduction is in accord with the findings in the oft-quoted case of Pearson Irvine.[8]

So far we have considered conditions marked, as far as the lung is concerned, by nothing but simple lack of muscle movement. Further confirmation is provided by examples of pathological conditions, for instance:—

(e) *Cardiac dilatation*, when associated with pericarditis, is recognised as a condition in which deflation of one or both lower lobes occurs. The so-called rheumatic lung [9] is an example of deflation with an avirulent infection. I have no X ray evidence to show that the diaphragm is elevated. The physical signs—raised apex beat and liver dulness, with diminished epigastric protrusion and excessive thoracic breathing—indicate elevation. But further, in cases of cardiac dilatation due to valvular lesions, with crepitations (so-called œdema) of the bases, when sudden death occurs—as by rupture of an aneurysm into the pericardium—the lower lobes show the typical appearance of deflation and no œdema is present. There is no obstruction to bronchi. Respiration is preponderatingly thoracic. Livingstone and I have shown experimentally in rabbits that certain interferences with the heart through the open pericardial sac causes an elevation of the diaphragm. So-called "back-pressure lungs" are, in my opinion, merely deflated, and œdema, as in other conditions, is only a terminal event.

(f) *In acute pleurisy*, affecting one lower lobe, the homolateral costal diaphragm is raised and movement is diminished. In the early days the upper chest is held elevated, and the lower chest is fixed by intercostal and abdominal muscles. In cases of pleuropneumonia in which death occurs during the stage of red hepatisation, as the result of the pleurisy the lower lobe on the affected side is found actually to be smaller than its fellow—i.e., in the early days it is partially deflated. The main bronchi are not obstructed.

(g) *In localised peritonitis*—as, for example, that affecting the peritoneum in the region of the right lobe of the liver—an elevation of that half of the diaphragm, with diminished movement, is found by X ray. The restricted respiration is carried out by elevation of the chest—scalene action—and upper thorax expansion, deflation of the corresponding lower lobe being marked.

(h) *In cases of diphtheria* with paralysis of the diaphragm the condition of the lungs described by Pasteur [10] is one of deflation on which œdema is frequently superadded. In these patients the supine posture is adopted.

SUMMARY.

The foregoing observations show that whenever the respiratory effort is at a minimum, and the individual in a reclining or supine posture, the capacity of the chest diminishes. As soon as these conditions arise, the lung commences to deflate, this deflation being mainly seen in the lower lobes and being independent of bronchial obstruction. Toxæmia—or other conditions producing lowered vitality—exerts an effect through muscular weakness and greater passiveness of the subject, while local conditions influencing the height of the diaphragm further accentuate the deflation.

In adults, deflation is marked in the course of 36 hours; in children it is detectable within half an hour. The signs can disappear readily if the patient be induced to take deep diaphragmatic inspirations. When quiescence is resumed, deflation promptly recurs. It is more accentuated when the costal margin is unstable as the result of lack of action of the abdominal muscles. This defect is especially marked when the muscle has been injured, as during operation. The condition is typically found in people who remain in one posture because they are very ill or physically weak, or because pain prevents movement. The fundamental cause is the reduction of the necessity for a large air entry, and it is not necessary to postulate any other causal factor. The point to be accentuated is that deflation of the lower lobe occurs in all individuals who recline in one position without exerting themselves. If the lung is temporarily expanded or inflated deflation recurs at once on resuming quiescence.

The Influence of Deflation on Post-operative Conditions.

When pulmonary complications follow operation, deflation must be regarded as the primary condition on which further changes which occur in the lower lobes are implanted, and no explanation of pathological changes can be complete or accurate which does not take this deflation into account.

SIMPLE DEFLATION.

A lung deflated as described possesses a circulation, and the activity dependent thereon continues—e.g., in the nutrition of the lung in the function of reproduction of the cells lining the alveoli and of the bronchi, in the function of the mucous glands in producing mucus in varying quantity, and in the general response to infection. With little irritation this will produce no clinical manifestation, so we find:—

(1) *Simple deflation.*—In most instances this is not detected. No symptoms occur to attract attention. It merges into:—

(2) *Simple deflation with secretion:* (a) *Non-pathogenic.*—Sometimes a loose, shallow, unproductive and frequent cough occurs, suggesting a liquid mucus which is not brought up to the mouth. It resembles the typical cough in the case of an empyema. Frequently in uncomplicated cases of deflation, as after operation, the mucus is expectorated at the end of three to seven days. It may be grey in colour, or green or dull red, not giving a test for blood. Besides mucus and shadow alveolar and bronchial cells, a number of bacteria are present which, in the absence of polymorphonuclear leucocytes and pyrexia, are clearly acting not pathogenically but as parasites or saprophytes, and they explain the colour of the mucus. In some cases there is a tendency to the secretion of an excess of mucus. The secretion may vary in consistence from that of a bronchorrhœa

to that almost resembling fibrinous bronchitis, but such extremes are rare.

(b) *Pathogenic.*—If the bacteria act pathogenically the secretion becomes purulent, and pyrexia and signs of bronchitis with distress on coughing result. Inhalation of infected material into the deflated lung consequent on deeper respiratory movements gives rise to various conditions of bronchitis, bronchiolitis, broncho-pneumonia or pleurisy. In such instances pleurisy is not very acute. The bronchus may be infected before, during, or after the operation. These two types are readily understood.

THE MASSIVE PULMONARY COLLAPSE ATTACK.

This type was originally described by Pasteur.[1] Usually, though not invariably, the onset is very acute, with pain, orthopnœa, cyanosis, and general distress. These symptoms, however, pass off in 48 hours. On the affected side the lower lobe of the lung is found to be airless. Although the upper lobe is over-expanded the air entry is poor. The heart is displaced toward the affected side, which, on measurement, is found to be diminished. On the unaffected side the lung is over-distended and the air-entry is good. If both sides are affected, the heart is mesial. Purulent secretion may or may not develop. The genesis of this condition is obscure, and three main theories have been put forward to explain it, none of which take cognisance of the condition of deflation which exists in the early days after operation, and therefore prior to the attack.

1. The first theory is the original theory of Pasteur,[1] which ascribed the condition to sudden paralysis, which might be reflex in origin, of some of the respiratory muscles. He clearly likened the condition of these to the paralysis of other muscles which is found in diphtheria, and ascribed the various changes directly to a sudden lack of distending power.

2. The second theory is that the condition is the direct result of obstruction to the bronchi. This obstruction may be due to mucus or to spasm or paralysis of the bronchial muscles. The theory is based upon the well-known experiments of Lichtheim[11] and the results of observations on foreign substance in the bronchial tubes. In most cases the holders of this theory—Elliott and Dingley,[12] Boland and Sheret,[13] Santé and Morrison[14]—would not admit the rôle of respiratory muscular defect; while others (Lee,[15] and Jackson and Lee[16]) would allow that embarrassed respiration may play a part. Woodburn Morrison[17] is driven to invoke the necessity of vagal or sympathetic action.

3. The third theory suggests pulmonary emboli as a causative factor (Cutler and Hunt[18]), such emboli being held to be not only of venous origin, but travelling also through the lymphatics. By both paths the origin of the emboli is placed in the neighbourhood of the wound, and in many cases sepsis is admitted as a contributory factor.

Each of these theories evades recognition of the physiological condition of the lungs found in the resting patient in the early days after operation, but tacitly assumes that the lungs are in the naturally expanded condition found in ordinary life, and accordingly seeks to explain the sudden change from such a state into that found in the massive collapse attack. This false premise renders criticism of these theories almost unnecessary and certainly difficult. The points requiring explanation are the suddenness of the attack, its duration, the pain and pyrexia, as well as the relationship of the physical condition of the lungs and heart found at the moment to the condition of deflation of the lower lobes present before the attack.

Theory 1.—In his post-diphtheritic cases Pasteur[10] used the term paralysis to indicate a condition of the diaphragm similar to the paralysis of the eye or pharyngeal muscles. Basing the condition of the post-operative massive collapse attack on the foundation of paralysis of muscles in diphtheria, he considered that the condition of the lung was a similar development to that found in diphtheria, but that, instead of occurring gradually, the onset came with cataclysmic suddenness. When limited to one lobe this was due to paralysis of one phrenic nerve and of half of the diaphragm.

Except in cases of direct pressure on or injury to the nerve, I have never seen true phrenic paralysis. Unilateral phrenic paralysis, when uncomplicated, gives rise to different signs.[7] Further and more important, as underlying the pathology of the collapse attack, in these cases of post-diphtheritic paralysis so-called), the diaphragm can be induced to contract. Physical signs show that it is elevated, but when the lower thoracic expansion is controlled—depressing the lower ribs by axillary pressure and bringing them towards the middle line—the diaphragm contracts, the epigastrium is protruded, and the signs of collapsed lung disappear. In ten cases of this condition I have never failed to demonstrate this point, a fact which shows that in these post-diphtheritic cases the condition is really one of marked postural deflation. I agree that a physiological lack of distending muscular power is the basis of deflation, but I do not agree on the mechanism by which it is suggested that the acute collapse attack is produced. Further, pain and pyrexia are not explained.

Theory 2.—Deflation certainly occurs without endobronchial contents. This fact is against the theory which explains the condition as analogous to that of a foreign body in a large bronchus. It is difficult to see how a large bronchus can be occluded by muscle spasm. Occlusion could occur in a small bronchus, and such action might be regarded as a protective mechanism for the part of the lung rendered airless. The theory does not explain (1) the constancy of the deflation in the lower lobe, (2) the irregularity of its distribution in the lower lobe, (3) its extension in the upper lobe on rare occasions, in each instance without symptoms or bronchial obstruction, or (4) the fact that what I have termed deflation with secretion occurs, and without these acute symptoms. It is possible that a spasm of a bronchiole muscle can withstand the depressive power of an active diaphragm; if the spasm could do so it is difficult to conceive that with a contracting diaphragm the imprisoned air could be absorbed. Nor does it explain the rapid expansion of the lower lobes which occurs when diaphragmatic movements are induced. Still less does it explain the suddenness of the onset of massive collapse or the pyrexia or pain.

Theory 3.—Deflation occurs without evidence of emboli. Such limitation of distribution does not occur in other conditions in which emboli invade the lung.

None of these three theories takes cognizance of the fact that the massive collapse attack comes on as a rule a day or so after the operation, and is therefore implanted on the condition of the lung existing at the moment. This I have shown to be one of deflation affecting both lower lobes, and without temperature or pain. The attack is associated with pyrexia, indicating infection, and acute pain. As a rule the onset is sudden and unexpected. Occasionally a sensation of something impending is present. The affected side is small below, expanded above and motionless, and air entry is deficient.

In my opinion these massive pulmonary collapse attacks are really instances of acute pleurisy occurring when the lower lobes of the lungs are already in a condition of simple deflation, and my reasons for this opinion are as follows:—

(1) In many of the instances described the presence of pleurisy has been admitted, either in the account of cases which have recovered, or in that of the post mortem. (Though admitted to be present, it has been excluded as the cause of the attack.)

(2) Muscles acting on the affected side of the chest behave in the same manner as they do in cases of pleurisy—i.e., (*a*) the lower intercostals are firmly contracted, (*b*) the scalenes and upper intercostals are contracted also, but to a lesser degree, in the early stages, (*c*) the abdominal muscles acting on the lower thoracic margin are similarly involved.

(3) These lower intercostal muscles are intensely sensitive to pressure, which increases the pain exactly as in pleurisy from other conditions—e.g., pneumonia. The abdominal muscle, which has been incised at operation, when forced into a protective contraction is intensely painful. (Generally in pleurisy the abdominal muscles are not sensitive to pressure.)

(4) The sudden onset of pain corresponds to the similar onset in many cases of pleurisy, and in both conditions may be first noticed following a movement.

(5) The duration of the acute pain is about 36–48 hours, which is also a common time for the duration of pain of acute pleurisy.

(6) Relief in both pleurisy and the collapse attack is immediate when suitable restriction, as by a tape and spring, is applied. Mechanical restriction of chest movement, by performing the work of the intercostal and abdominal muscles, allows these to relax, hence the relief of pain.

(7) Pleurisy explains the temperature as well as the physical signs—i.e., (*a*) tonic contraction of intercostals causing a diminution in the size of the lower chest; (*b*) tonic contraction of the elevated costal diaphragm on the affected side; (*c*) persistence of a state of deflation already present before the attack; (*d*) deficient air entry resulting from imperfect expansion of the over-distended upper lobe (it remains over-inflated, though silent, when the scalene and upper intercostals are tonic, but deflates in those cases in which, a day or so later, the upper intercostals go out of action); (*e*) compensatory over-expansion of the other lung. (*b*) and (*c*) explain the shift of the mediastinum to the affected side.

The essential difference between a massive collapse attack caused by pleurisy and an ordinary pleuritic attack lies in the facts that in the former the lower lobe is already deflated, and in many cases a muscle in which tonic contraction occurs has been incised, and contraction is painful. The uncertain point here is the assumption of a tonic or spastic condition of the costal diaphragm, as a result of pleurisy. I think it justified because I find the same changes (elevation and lack of motion) in the diaphragm in these cases of collapse as are found in acknowledged cases of pleurisy. The infection has in most cases come through the diaphragm from below, and I am ascribing to the diaphragm a reaction which certainly occurs in other muscles under like circumstances.

Hence I consider that these cases described by Pasteur as massive collapse attack of the lungs are instances of well-marked simple deflation in which the condition on one or both sides is suddenly modified by the onset of an acute pleurisy. I do not believe that bronchial obstruction or embolism have anything to do with them.

DEFLATION OF A WHOLE LUNG.

The explanation of deflation of a whole lung is more difficult because the condition is seldom seen in civil practice, and is not essentially a post-operative condition. Under war conditions slight or severe injuries to the chest were exciting causes, producing deflation of the whole lung on the same side as the trauma, or on the opposite side. This injury might be to the upper or lower part of the chest wall. It raises questions of a reflex inhibition of expansion and of injury by contra-coup. (In many experiments to elicit a reflex inhibition of one-half of the diaphragm only very occasionally was evidence obtained at all, and then only by a reflex arising from the chest wall on the application of heat or cold. The effect was slight and incommensurate with the stimulus.) In two cases of chest injury seen recently, the one severe and the other slight, both in children, the whole of the left lung was out of action—deflated. The diaphragm was high and the outline not clear, so that immobility was not definite. The scalenes and upper intercostals on the left were toneless, giving rise to a flattened and motionless upper chest, while the lower intercostals were tonic. Both the upper and lower areas of the chest were thus diminished. In these two cases the mechanism of production clearly was defective muscular action.

This brings all four types of deflation into one category—deficiency of muscular action in expanding the lungs. At present we must consider the fourth condition as differing from the first three, inasmuch as the upper part of the thorax is out of action, the whole lung being affected.

Therapeutic Indications.

The conclusion to which we have been led is that, whenever an individual remains at rest in one posture with respiratory exchange at a minimum, deflation is bound to occur. Youth, early adult life, certain types of breathing and conditions of disease producing marked weakness or unconsciousness, naturally increase the tendency to this condition. If the individual is disturbed, the expansion of the lung may be partially or fully restored for the time being, only to deflate when the disturbance is discontinued. Local lesions, injury or disease may modify the distribution or extent of the deflation, and the clinical picture may be altered by complications occurring when the deflation already exists, but these are addenda and should not be allowed to disturb our conception of the basal physiology of the condition —a deflation of the lung resulting from diminished muscle action. The more severe the operation, especially in the upper region of the abdomen, the more marked will be the deflation.

The occurrence of massive collapse attacks has suggested that therapeutic measures should be applied to every abdominal operation case, in order to obviate post-operative pulmonary conditions. Among such routine measures are the administration of carbon dioxide to produce deep inspirations, and turning the patient on his side, with or without smacking. Any routine treatment is a mistake, because so many escape any symptom at all, and to put patients to pain and distress within a few days of the operation is certainly unnecessary and inexpedient. It is not advisable to promote deep breathing if there is a likelihood of carrying infection to the deeper part of the lung.

Simple deflation.—So long as the individual is quiescent, only requiring the employment of a small portion of his respiratory area, there is no need for the lung to be fully expanded, or for muscular action causing pain to be encouraged. More lung will become inflated as more respiratory changes are necessitated. The majority of subjects of operation pass through these stages without symptoms which attract attention. It is therefore unnecessary, to say the least, to adopt any routine measures which aim at promoting once or twice a day expansion of the lung accompanied by fatigue and distress.

Simple deflation with secretion.—During the course of the administration of a general anæsthetic, respiratory movements of the greatest intensity are induced, and all parts of the lung must be over-distended. At this time there is every opportunity for infective material to be aspirated. After the operation the breathing becomes as shallow as possible. As a result, an excess of mucus may be secreted in the large bronchi. In many cases this is not pathogenic. There can be no object in causing it to be inhaled into smaller tubes. If the respiratory tract has become infected, either in the main bronchial tubes or below the level of the cough reflex, no method of fully expanding the lung is going to improve matters. Sputum is viscid, coughing painful, and every effort exhausting. The lung requires time to develop resistances, general and local: serum, leucocytes, alveolar cells, and mucus. The condition may be made worse if the infection is aspirated to the very surface of the lung, and pleurisy results. Further, when therapy to expand the lung has been employed, directly it is discontinued the lung proceeds to deflate, progress only broken by the cough and the next therapeutic application.

The massive collapse attack, in my opinion, is the result of pleurisy, which may arise by a spread to the surface from the deeper parts of the lung through the visceral pleura, but which more usually (where no pulmonary symptoms have preceded) originates from sepsis arising from the seat of operation through the parietal pleura. Forced expansion will not improve this. It is important to see that full respiratory activity has been reacquired by the subject after operation, especially if the lungs have been involved, but this should not be investigated until 14 days or so after operation, or when the patient is getting up.

I therefore strongly deprecate methods which aim at expanding the deflated lung in the early stages after operation. In the great majority of cases no effect of the deflation is perceptible, and the means suggested are unpleasant; where symptoms arise the procedure on theoretical grounds is inexpedient, and a paper by Dr. Fuller[19] confirms that practically it is detrimental.

Points to be recommended are:—

(1) After operation the sitting-up posture assists respiration because gravity helps expiration by allowing the thorax to descend, counteracting the inspiratory elevation of the scalenes and intercostals and obviating the necessity for abdominal muscle action for this purpose. This is especially true of the type with thoracic breathing. The individual should be allowed to choose the position which is comfortable, and be encouraged to change frequently.

(2) Bandages should *not* be too tight above the level of the umbilicus. It is here that abdominal protrusion in diaphragmatic inspiration is greatest in degree. On the other hand, a tight bandage supports the incised muscle. It is largely a question for the individual patient and the type of breathing he has developed.

(3) Movements of head and arm and of all sorts, as soon as these no longer cause pain, should be encouraged as inducing contraction in abdominal muscles and so relieving muscle monotony. The contraction of the diaphragm is increased, its level is lowered, and a step is taken towards expansion of the lower lobes.

(4) When non-viscid sputum is present: (*a*) the mildest symptom is half-hearted cough 18 hours or more after operation, sometimes as much as every half-minute, with no expectoration. Eventually some mucus is expectorated, usually after four or five days. This has accumulated in the "test-tube bronchi." There is not enough energy to get air behind it. As a rule, this requires no treatment. (*b*) If the condition is troublesome, the patient should be instructed to breathe in as slowly and deeply as possible and then to give a short, sharp expiration, which produces expectoration. During this effort he should support the lower thorax with a hand in either lower axilla, the nurse supporting the abdomen with her hand on the bandage over the area of incision. (*c*) After the third or fourth day, in addition, he may try gently turning into such a position that gravity helps the mucus to run out of the bronchus into the trachea, where it can be brought up. (*d*) If pyrexia is present and the sputum is purulent instead of mucoid, a Burney Yeo inhaler should be employed with the usual antiseptic inhaling fluid, the inhaler to be worn as continuously as possible. The success of this is dependent on the manner in which it is introduced, on the instruction that deep breathing is contra-indicated, and on seeing that the face is not burned by the creosote.

(5) Should the temperature rise after the lapse of 24–48 hours with respiratory distress, the sputum will at first be scanty and viscid, and the cough irritating and non-productive. Treatment should chiefly be directed to rendering sputum liquid and easily expectorated. Most important is the rapid administration of alkalis well diluted, every hour or two hours until the urine is alkaline, and of medicated vapour inhalants and such anodynes as are safe. In the common type of condition, beginning on the second or third day, the temperature will be down and expectoration easy, though the cough is still painful, on the fourth or fifth day.

(6) When more severe, the infection may be spread to deeper parts. The cough and associated deeper respirations expand the lung and fresh areas are infected. Hence arise bronchiolitis, broncho-pneumonia, pneumonia, and late patchy pleurisy, with the usual sequelæ. Treatment is such as is usually employed for these conditions. I have not met with cases of such severity as to require that the bronchial contents should be removed by mechanical means. The upper lobes alone are quite capable of coping with the respiratory requirements when at rest.

The distress of the collapse attack, as stated above, is readily relieved in a few minutes by controlling the movement of the side affected, as is the pain in pleurisy. A broad tape with a spring inserted is most efficient. The pain on coughing is not extinguished in either of these conditions, and for the same reason. A septic pleural effusion with its consequences may, of course, develop in pleurisy following operations, as in other forms of pleurisy, and requires similar treatment.

PROPHYLAXIS.

The troublesome time for the development of pulmonary infections is during the earlier days after operation. The longer the interval the greater the recovery from shock, asthenia, disinclination to move, and pain on so doing, and consequently from the deflation in the lung present in the earlier period.

The infection may have spread from a chronic condition in the patient's respiratory tract or mouth, when, generally, it does not lead to very severe results, the patient being no doubt to some degree protected. The greater the care taken to eradicate sepsis in these areas before operation the better. Probably the more severe cases arise from operation when the subject is starting a cold; I have seen many instances of this. The pulse chart shows an increase of rate within the 36 hours and the temperature chart a slight rise within the 24 hours preceding the operation, and the patient has admitted that he was not well but has thought the cause was fear. Except in cases of emergency, if there is a suggestion of acute respiratory indisposition, the operation should be postponed, though such a course is upsetting to all concerned. One of the worst cases of post-operative pulmonary infection I have seen arose after an operation on a quiescent appendix when the patient was developing a cold and had a temperature of 99·2° F. It is widely recognised that pulmonary complications in the majority of cases follow within 48 hours of the operation; 48 hours or less is a common incubation period in ordinary life for the development of catarrhal symptoms after exposure to infection. There is therefore every reason to surmise that signs and symptoms occurring 24–48 hours after the operation are attributable to infection about that time. Hence prophylaxis against infection at the operation is a most important point. In addition to the lowering of reflex activity by morphia, the drying-up of secretion by atropine, the suppression of the naso-pharyngeal filter by a mouth gag, and the excitation by the anæsthetic of very deep inspiratory efforts in a moist superheated atmosphere, there is considerable overcrowding in the immediate vicinity of the patient.

Of four patients operated upon in one afternoon, three developed acute respiratory complications and one died. A member of the operating team was developing an acute cold. Among the populace there seems to be an idea, half believed by the medical profession itself, that the infections of doctors and nurses differ from those of other people and are not communicable. Liability to infection from the surgical team, from ward nurses in attendance, and from visitors ought to be avoided. Face masks are insufficient protection in such conditions. Persons with acute infections should not be allowed near the patient during the early days after operation.

CONVALESCENCE.

It is just as important to see that full respiratory movements are restored after any abdominal operation as it is after pleuritic affections. There is the greater tendency for the individual who inclines to thoracic breathing to neglect fully to re-employ the diaphragm. As a rule, this defect rights itself as exertion increases; until it does so complaints indicative of dyspnœa, asthenia or lethargy, and of pain about the sternum, are apt to be made. When correct diaphragmatic breathing is restored by re-education, these symptoms disappear, and no patient should be discharged before it has been obtained. Failure to re-educate the diaphragm after prolonged rest is a common cause of the illness of the patient who has "never been well since the operation." In certain obstinate cases where puncture has to be made to restore activity, carbon dioxide inhalations might quite well be tried first. Such cases are very rare.

I have endeavoured to stress the importance of deflation as occurring after operations; its recognition is equally necessary in the consideration of many other pulmonary conditions. Though frequently preached, the significance of deflation has not yet been generally assimilated.

Conclusions.

(1) The total volume of the chest is diminished when the reclining or supine posture is assumed. (2) The capacity and expansion of the upper part of the chest are increased. (3) The capacity and expansion of the lower part are diminished. (4) Inflation of the upper lobe depends on expansion of the upper part of the thorax, combined with tone in the diaphragm. (5) Inflation of the lower lobe is dependent on a low level of the diaphragm, and probably on inspiratory descent of the costal portion. (6) Deflation occurs in all persons who are quiescent when reclining or supine, and therefore is present in most of our bed patients, particularly those subjected to operations. (7) In the great majority of cases no symptoms follow. (8) Infection, if present beforehand, may be spread. Frequently it is acquired at the time of the operation. (9) Therapeutic expansion of the lung in the early days after operation as a routine measure is not advisable; but (10) Before discharge, voluntary control over the diaphragm should be fully acquired.

ALBUMINURIA COMPLICATING PREGNANCY.

BY G. F. GIBBERD, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT OBSTETRIC SURGEON, GUY'S HOSPITAL.

PART I.*—THE DANGERS.

So much has been heard lately of the mater risks that pregnancy, especially abnormal pregnan entails that it will not be out of place to consi the ultimate reason for taking these risks. The rea of course, is the child; and the greater the v placed upon the child, the greater will be maximum risk that is considered justifiable for th mother. In the particular instances that we are considering—i.e., pregnancies complicated by albuminuria—it will be an advantage to know exactl how often a fruitful result is attained. There can no justification, beyond the hope that it might h been different, in taking any avoidable maternal ri for the sake of an abortion, a macerated fœtus, or a infant which dies in early infancy from prematurity.

In cases of albuminuria the dangers to the fœtus are two: (1) the risk of abortion or death in utero as the result of the toxæmia; (2) the risk of death from prematurity in early infancy in cases where pregnancy has been terminated either accidentally or by intent, sometime before full term. In the inuria during pregnancy is running several risks, which may conveniently be summarised as follows:—

---

* Part II., dealing with treatment, will appear next week.

1. *The danger of eclampsia.*—We have seen that, provided reasonable care and treatment are forthcoming, this is very small.

2. *The danger of developing patent chronic nephritis.*—With the standards of treatment that have in the past been considered adequate this danger is considerable—about 10 per cent.

3. *The danger of developing occult nephritis.*—With he standards of treatment that have in the past been considered adequate this danger is probably in the ion of 50 per cent.

4. *The danger of losing her fœtus by maceration in ro.*—When induction of premature labour is resorted or inductions that have in the past been deemed sonable, this danger is about 9 per cent.

—. *The danger of losing her infant in the neonatal iod from prematurity.*—When induction of premature labour is resorted to for inductions that have the past been deemed reasonable this danger is o per cent.

above estimates of the risk are true only for ly healthy patients. If there is any permanent damage before pregnancy the risk becomes all the greater, but even as it is set out above it is surely sufficient cause for us to look critically upon our accepted treatment of toxæmia of pregnancy, in the hope that we may find some places at least where improved methods may be instituted.

THE ÆTIOLOGICAL IMPORTANCE OF THE ELEMENTARY BODIES IN VACCINIA AND FOWL-POX.

BY J. C. G. LEDINGHAM, C.M.G., D.Sc., M.B. ABERD., F.R.C.P. LOND., F.R.S.,

DIRECTOR AND BACTERIOLOGIST-IN-CHIEF, THE LISTER INSTITUTE; PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON.

THE purpose of this brief communication is to place on record some new observations which, so far as they go, support the claim that the Paschen and Borrel bodies met with in the lesions of vaccinia and fowl-pox represent the actual viruses of these respective diseases. During the past six years, while occupied with various studies on these viruses, I have given a good deal of attention to these minute bodies, which occur with absolute constancy in the lesions, and are readily detectable by appropriate staining methods. That in the early stages of the vaccinial lesion in the skin of the rabbit these bodies increase enormously in numbers and appear to be quite free, I have noted elsewhere. In the later or healing stages of the lesion the bodies congregate in the neighbourhood of the inflammatory cells of the exudate, and the impression obtained has been that the bodies are actually phagocyted, though, so far, phagocytosis has not been proved, owing to technical difficulties of demonstration, which, however, may yet be overcome. The behaviour of the bodies from their first appearance in the lesion, their increase in numbers as the lesion progressed, and their final aggregation among cells in the exudate suggested analogies at least with that of frankly bacterial invaders associated with skin phlegmons.

In fowl-pox the status of the Borrel bodies as possible agents of this disease has very materially advanced in the past three years, particularly since the experimental demonstration by Woodruff and Goodpasture (1929) that a single Bollinger inclusion body can infect. As fowl-pox virus is filtrable through the lower grade filters which retain bacteria, the infecting agent in the large Bollinger body *must* necessarily be something considerably smaller. Since then I have, like the American workers, been successful in demonstrating that the large Bollinger inclusion body which is so striking a feature of the fowl-pox lesion is really an aggregation of the minute Borrel bodies. Giemsa-stained preparations showing this relationship between the Bollinger and Borrel bodies were demonstrated at the International Congress of Botany in Cambridge in August, 1930, and at the Pathological Society of Great Britain and Ireland in January, 1931. To many minds this proved relationship between a minute body of dubious nature and a large structure like the Bollinger body, which has been known and variously interpreted for 60 years, would, of itself, supply cogent evidence for the view that the Borrel body represents the actual virus. I may add here that in potent bacteria-free filtrates, both of fowl-pox and of vaccinia virus, I have succeeded in demonstrating elementary bodies in stained deposits from filtrates spun at high speed. It was obvious, however, that other lines of inquiry which might yield crucial evidence in support of the ætiological relationship had to be explored. One line of inquiry was clearly serological, in view of the mass of evidence now available that extracts prepared from vaccinial and small-pox lesions fix complement, or are specifically precipitated, in the presence of anti-vaccinial sera. The work of Gordon (1925), Bedson and Bland (1929), Burgess, Craigie, and Tulloch (1929), and Craigie and Tulloch (1931) may be alluded to in this connexion.

The only evidence I can find bearing on the influence of specific immune serum on these elementary bodies is that recorded by Prof. Paschen, who found, and figured, in stained preparations of precipitates obtained by the interaction of "immune serum" and lymph from vaccinated children, agglutinated masses of elementary bodies.

During the past five years I have made repeated but, until recently, quite unsuccessful attempts to secure from vaccinial and fowl-pox lesions pure suspensions of elementary bodies that might be employed for serological test, and especially for agglutination. From the repeated failures it gradually became clear that certain requisites were essential for success. It was advantageous to employ material from early lesions (on skin of rabbit or comb of fowl) in which the elementary bodies were numerous and free. Such material was triturated thoroughly in a mortar with distilled water. The crude suspension was then shaken up in a flask with at least an equal volume of ether, and allowed to stand on the bench for at least 24 hours, being frequently shaken up during this period. The suspension was then centrifuged at high speed. The upper layer of ether and the large middle layer of light fatty matter which had risen to the surface were removed, leaving an underlying opalescent fluid, and occasionally a small deposit.

This underlying layer, together with the deposit, was again centrifuged at high speed for at least one hour (9000 revolutions per minute). The resulting deposit was collected after discarding the supernatant fluid. This small deposit, consisting of elementary bodies and some debris of cells, was then taken up and suspended in formolised saline (1 in 400). By further fractional centrifugalisation of this suspension and natural sedimentation, it was possible to eliminate practically all of the grosser debris, leaving only the elementary bodies. At all stages of the process the degree of refinement of the suspension was controlled by microscopical examination of appropriately stained samples.

Microscopical examination of the final suspensions in formolised saline by Giemsa (long method) or carbol fuchsin, preceded by Loeffler's flagella mordant, revealed a carpet of uniformly distributed elementary bodies.

AGGLUTINATION TESTS.

These suspensions have been tested with various sera but, so far, only on a small scale. The sera include normal fowl and rabbit sera, fowl sera, both from recovered fowl-pox and from hyper-immunised fowls, and antivaccinial sera, obtained by hyperimmunisation of rabbit and horse. The tests have been most conveniently made in hanging drops on coverslips in vaselinised chambers, which permit the microscopical examination of the progress of any reaction taking place between the two reagents. It has emerged that the elementary bodies of fowl-pox are not clumped by sera of young normal chicks in dilutions of 1 in 5, but are clumped by the sera of fowls at various periods after recovery from fowl-pox in dilutions ranging from 1 in 20 to 1 in 160. Sera of hyperimmunised fowls also clump the elementary bodies strongly in fairly high dilution. Similarly the elementary bodies of vaccinia (Paschen bodies) are clumped by hyperimmune sera in high dilution, but not by normal rabbit sera in dilution of 1 in 5. The agglutination experiments so far have been largely qualitative, with a view to establishing the fact that the elementary bodies are agglutinated in the presence of the corresponding antiviral serum. Quantitative titrations will be undertaken later, now that a satisfactory technique has been secured.

The clumping of the elementary bodies in the hanging drops can be readily followed, and the picture presented is in no way peculiar. The clumps have also been examined by various staining methods, which clearly reveal their composition.

SUMMARY AND CONCLUSIONS.

Homogeneous suspensions in formolised saline of the elementary bodies met with in vaccinia and fowl-pox (Paschen, 1906; Borrel, 1904) have been secured, which are free from other elements. The bodies in such suspensions are agglutinated by the sera of animals (fowls and rabbits) which have recovered from fowl-pox or vaccinia respectively or which have been hyperimmunised. So far as tests have revealed, they do not appear to be agglutinated, even in dilutions of 1 in 5, by normal sera. The agglutinated masses from hanging drop experiments have been appropriately stained, and shown to consist solely of these bodies.

The new data support the original claims of their discoverers, on grounds of association alone, that the elementary bodies represent the actual infecting agents. With recently reported improvements in methods for cultivating certain viruses in vitro it may be possible to determine whether growth of "virus" as determined by animal experiment is associated with corresponding growth of elementary bodies.

INFANTILE HYPERTROPHIC PYLORIC STENOSIS.

SYMPTOMATOLOGY, TREATMENT, AND PROGNOSIS.

BY CAMERON MACLEOD, M.B. LOND., F.R.C.S. ENG.,
LATE SURGICAL REGISTRAR, THE MIDDLESEX HOSPITAL.

ALTHOUGH infantile hypertrophic pyloric stenosis is observed relatively infrequently in a general hospital, it has seemed profitable to study a small series of patients with special reference to the after-history in relation to the treatment adopted. At the Middlesex Hospital, between the years 1919 and 1930, 18 children were treated for this malady. I have personally observed and followed up seven of these, and I have also analysed the remaining 11 cases and investigated their after-histories.

If the 18 cases are arranged chronologically it is found that the first five (1919–1924) were treated medically, while the remaining 13 were treated surgically by Rammstedt's operation. This illustrates the trend of opinion in this country. In Barrington Ward's series[1] of 359 cases, operative treatment was adopted in 310. In 1917, one case was operated upon and died; of nine cases treated medically seven died. In 1925, 54 cases were operated upon with one death (1·8 per cent.); one case was treated medically and died. In 1927, 25 cases were operated upon, only one child dying (4 per cent. mortality); no case was treated medically. In Poynton's[2] series of 100 cases there were 20 deaths, a mortality of 20 per cent. In the present series of 18 cases, all five patients treated medically recovered, while among the remaining 13 treated by Rammstedt's operation there were three deaths.

Wolff,[3] of Eisenach, gives a series of 98 cases from 1912 to 1930. Of these only six were operated upon, and among the 92 treated medically there were only two deaths. These are truly remarkable figures and form an interesting contrast with the method of treatment and results obtained in this country.

Ætiology.

In three patients the symptoms began at or soon after birth. In the remaining 15 the average age of onset was 3½ weeks, the earliest being 12 days and the latest 5½ weeks. There was the usual preponderance of males, all but one being of this sex. G. F. Still drew attention to the frequency with which first children are affected. In 299 cases in Barrington Ward's series, 171 (57 per cent.) were first children of the family. In the present series of 17 male children, eight (47 per cent.) were in this category.

Although *phimosis was at one time* considered to play a part in the production of the condition, *it is difficult* to understand its influence. Of 17 patients, four were Jewish and circumcision had been performed on the eighth day. In two other cases circumcision had been performed on the ninth and eleventh day respectively. Amongst the remaining 11 cases, phimosis was said to be present in four only. In one of these, circumcision and medical treatment led to a complete cure without operation. In another, circumcision was performed at the same time as the Rammstedt operation. Of 12 patients still living, five are uncircumcised. These findings suggest that phimosis was not an ætiological factor.

In none of the cases was there any relationship between the parents. All except two of the children were breast-fed from birth for varying periods before other preparations were tried. One of these two was fed on Allenbury's Food No. 1 up to the time of onset of symptoms. The other was fed on Nestlé's Milk, as "he did not take to the breast."

Symptoms.

Of the symptoms, vomiting was the most important. In 14 cases it was forcible or projectile in character. It usually occurred immediately after each feed, but occasionally after every third, fourth, or fifth feed, and rarely were all feeds vomited together at the end of the day.

The forcible nature of the vomiting was very characteristic, and was described variously as being projected from 2 ft. to 3 ft. "right over the mother's clothes" or "over the side of the cot." In other cases it was described as being "just pumped up all at once," "whole of feed returned through mouth and nose as if pumped up," and "spout out as from a water tap." In three cases no note was made as to the character of the vomiting, and in one case it was not projectile and "just ran out of his mouth" at first once a day, then twice or three times, and then almost after every feed.

In three cases there had been slight vomiting after food from birth. In two of these it was said to be projectile in character.

Constipation was present in 14 cases and became marked when vomiting commenced, or shortly afterwards. Rarely constipation preceded the vomiting. In four cases it was absent, the bowels acting regularly or freely after each feed. Green stools were present in seven cases.

Wasting was present and usually marked in all cases. In 14 children in whom the birth-weight is known nine on admission were under the birth-weight. This drop in weight varied from 1 oz. to 1 lb. 10 oz., with an average of 10 oz.

Jaundice was present in one case for one week before admission, but had almost disappeared at the time of operation. The Wassermann reaction was negative.

Physical Signs.

A *pyloric tumour* was palpated in 11 of the 18 cases. In four patients *no note* was made as to whether a tumour was present or absent. All four were operated upon and a tumour found. In three cases palpation of the abdomen failed to detect any tumour. Only one was operated upon and a definite tumour was found at the pylorus.

In these patients, where a tumour was detected, it was usually found just above and to the right of the umbilicus. Occasionally it will be found rather far to the right, almost in the right lumbar region. The position of the tumour is not constant and may vary in place from time to time as a wave of peristalsis passes over it. As this wave reaches the pylorus it may be felt to contract and harden. In one case it was noted that the liver reached a distance of three fingers' breadth below the costal margin; this relative enlargement of the liver is common and partly accounts for the difficulty in detecting the tumour.

Visible gastric peristalsis was a prominent sign in 14 cases. In the remaining four it was, in all probability, also present, although no note was made to this effect. The abdomen is uncovered and watched during a demonstration feed. The wave appears as a large rounded ball near the left costal margin, passes across the epigastrium from left to right, and ends as a smaller rounded ball, as a rule just above and to the right of the umbilicus, but depending on the position of the pylorus. The rate is usually fairly rapid.

Medical Treatment.

This commenced with a glycerin *enema* ʒ *iii*, which was usually repeated in four to five days and then as often as necessary. Gastric lavage with a sodium bicarbonate solution ʒ i in a pint of boiled water was employed at first either twice or three times a day, reducing later to once a day, and finally omitting altogether about five to six weeks after commencing treatment.

Method of feeding.—One child was breast-fed throughout with supplementary feeds of citrated milk at night. Thirteen days after admission a phimosis was dealt with by "slitting up" of the prepuce, and vomiting occurred on only three occasions afterwards, and in three weeks the child had gained 5 oz. There was a final gain in weight of 14 oz. during a stay of seven weeks. Artificial feeding was employed in the other four children, e.g., as follows:—

Peptonised milk ℥ iss and boiled water ℥ss were given two-hourly by means of a stomach-tube. As an alternative albumin water ℥ii may be given. These were replaced subsequently by the same quantities of citrated milk and boiled water given at first by the stomach-tube, then by spoon, and finally by bottle. The amount was gradually increased until citrated milk ℥v was being given three-hourly.

Drugs.—In one case tinct. opii ♏ i with haustus bismuthi ʒ i was given six-hourly for diarrhœa with green stools. In another the following drugs were employed: tinct. belladonn. ♏ iii, tinct. camph. co. ♏ ii, and sodium bicarb. grs. iii. In all five children the vomiting gradually diminished, and finally ceased altogether. In one child visible gastric peristalsis continued, and had not completely disappeared on discharge from hospital. This child gained 5 lb. 8 oz. in five months. The other children gained 2 lb. 8 oz. in three months, 1 lb. in five weeks, and 14 oz. in two months, respectively.

Although constipation was a marked feature in all, the bowels became regular during treatment, two to three motions occurring every day.

Surgical Treatment.

PRE-OPERATIVE.

Although operation is undertaken as soon as possible after the diagnosis is made, at least 24 hours are required to prepare the child. It is usually performed on the first, second, or third day after admission. One child succumbed in which operation was delayed for 32 days after admission.

Twenty-four hours before operation enemata 3 oz. of normal saline with 5 per cent. glucose are commenced and repeated six-hourly. The child is breast-fed, if possible, every three hours until four hours before the time of operation, after which nothing further is given by the mouth. The last two feeds are given with a teaspoon. Subcutaneous saline 1½ oz. to 3 oz. with 5 per cent. glucose, is given into each axillary region 12 hours before and again two hours before operation into the thighs. Finally, 1½ hours before operation, the stomach is washed out with plain water, and the limbs are wrapped in warm cotton-wool and lightly, but firmly, bandaged from below upwards. Gastric lavage is beneficial for the associated gastritis, and relieves the distension, which adds to the difficulties of the operation. Subcutaneous salines and glucose restore fluid to the body and carbohydrates to the liver. A blood transfusion may be necessary. Absolute rest is maintained for one hour before operation.

No hypodermic injection is now given before the anæsthetic, although in most of the cases in this series atropine gr.1/200th was given half an hour before the time of operation. The child wears a woollen vest and a flannel gown, and is carried to the theatre in a warm blanket; one or more well-protected hot-water bottles may be placed between the folds under the child. It is most essential that the theatre and instruments necessary for the operation are ready before the child is brought from the ward, so that there is no waiting. The theatre staff should each know exactly what they have to do, being ready with lotions, porringers, &c., at the right moment to prevent any waste of time. The temperature of the theatre is an important point, and should be between 75° and 80° F. The table should be previously warmed by means of hot-water bottles.

The *anæsthetic* is given in the theatre with the child on the table. The choice of anæsthetic is important.

From 1924 to the end of 1927 six cases were operated on, and in two of them open ether was employed. One developed broncho-pneumonia on the eighth day, but eventually recovered; the other recovered without chest complications. In three cases chloroform and ether were used, and of these two died. One died the day after operation. The vomiting persisted, and at the post-mortem examination a small area of broncho-pneumonic consolidation was present at the right base. The other child died two days after operation; definite signs of consolidation developed at the left base. In one case no note was made as to the anæsthetic employed.

From 1928 onwards seven cases were treated by operation. In all cases gas and oxygen was given through a Boyle's apparatus. In some cases a little ether was added to the mixture. None of the children developed chest complications.

Gas and oxygen is undoubtedly the anæsthetic of choice, and the addition of a little ether at the same time does not appear to increase the danger to any extent. A specially small face-mask is necessary.

THE OPERATION.

Only the site of the operation is exposed. A paramedian incision, 2 in. to 2½ in. long is made high up to the right of the mid-line beneath the costal margin, the advantage of this high incision being that it allows the liver subsequently to protect the abdominal wound; this organ presents itself when the peritoneum is opened, and should be gently lifted up.

The pyloric tumour is delivered, and care is taken to prevent coils of small intestine or of transverse colon from protruding through the wound; the tumour is steadied, and held by the left forefinger and thumb. An incision is made through the peritoneum and superficial muscle-fibres at the junction of the upper and middle thirds of the anterior surface of the pylorus—this being a comparatively avascular area, the meeting place of the superior and inferior pyloric veins. On the one hand this incision extends as far as the duodenum, but not on to it, and, on the other, to a varying extent along the pyloric portion of the stomach. It should be remembered that the pylorus projects somewhat into the duodenum, and great care must be taken not to open the duodenum. The deeper layer of muscle is separated down to the mucous membrane with a blunt dissector or the handle of the scalpel, until the mucosa appears white and glistening and may bulge to some extent. The stomach may now be compressed, and air forced through the pylorus into the duodenum. In this way it may be possible to detect any injury to the mucosa; if the latter has been accidentally incised it must be sutured at once with fine catgut, and if it is thought necessary a piece of omentum sutured over it. The pylorus is returned, and the incision in the abdominal wall should be carefully but quickly closed in layers. The child is carried back to the ward, well wrapped up in a warm blanket, which should also cover the head.

The time taken for the operation was noted in four cases—viz., 6 minutes, 12 minutes, 15 minutes, and 23 minutes; in four, an accidental incision was made in the duodenal mucosa, which was sutured with fine catgut; all four children recovered.

During the operation the cot must be prepared. A hot-water pillow, freshly filled at a temperature of 118° F., is placed under the drawsheet, a folded blanket is in readiness to cover the child, and a small knee-pillow is placed in position. The remaining bedclothes are hung over the electric cradle, protected by a rough brown blanket. The foot of the cot is placed on blocks, and a screen arranged around it. Oxygen and brandy, and the wagon for subcutaneous and rectal salines, must be in readiness.

POST-OPERATIVE CARE.

On return from the theatre the child is placed in the cot, well protected from the light bulbs by the second blanket. The temperature and pulse-rate are taken hourly for 24 hours. If the temperature is rising, the limb bandages are removed. If it continues above 100° F., the electric cradle is removed; if above 101° F., a cold compress is given to the head, and if above 102° F., an ice-bag is applied almost touching the head. The water-pillow is filled every six hours, and feeding is begun four hours after operation. If the condition of the child is poor, rectal saline ℥ i to iii with glucose ℥ss should be given four-hourly, and, if necessary, subcutaneous saline with glucose ℥ iss into each axilla.

Feeds.—Begin four hours after operation.

4th	hr.	after	op.	hourly	feeds	of	1	dr.	for	6	feeds	from	spoon.
10th	,,	,,	,,	,,	,,	,,	2	,,	,,	3	,,	,,	,,

43rd	,,	,,	,,	,,	,,	,,	2	,,	,,	6	,,	,,	,,

3rd day. Further increase in feeds, return to three-hourly and night intervals, depending on condition of child.

The child is always breast-fed, if possible. Of the ten cases that survived seven were breast-fed.

Temperature.—In all the cases there was a marked rise of temperature immediately after the operation; it was not uncommon for the temperature to rise to 103° to 106° F. in the evening. On the first day a temperature of 102° or 103° F. was usual, rising to 105° F. on the second day. On the third day a gradual fall in temperature began; in two cases it was normal on the second day, and in another two normal on the third day; in the remaining six the temperature gradually subsided, and became normal and steady between the sixth and eleventh days.

Vomiting.—In no case was there projectile vomiting after the operation. In three cases no vomiting occurred at all; in the remaining ten cases there was some vomiting during convalescence. This commonly occurred at two distinct periods: (1) on the first, second, and third day after operation; (2) on the ninth to the fourteenth day. In none of these cases was there any vomiting in the intermediate period or later than the fourteenth day.

Bowels.—Enemata may be required after operation. As a rule they are unnecessary, as the bowels begin to act freely, four to five motions being passed for a few days after operation. On discharge, the child is generally passing two or three motions a day.

Weight and length of stay.—Where convalescence was uninterrupted, in eight cases the average gain in weight on discharge was 15 oz. for an average length of stay of 19 days after the operation. The actual gain in weight varied from 5 oz. to 2 lb., and the length of stay from 15 days to 24 days after operation.

MORTALITY.

Among the 13 cases operated upon there were three deaths.

One child was a very small, undersized, and thin baby of seven weeks, weighing 6 lb. 15 oz.; it had not been breast-fed. On admission gastric lavage was commenced, and continued daily, with some improvement. Operation was performed 32 days later. The anæsthetic employed was chloroform and ether, and the time taken for the operation was 15 minutes.

Subcutaneous salines were given afterwards, but the vomiting persisted, and the child died the next day. Post-mortem, the body-weight was found to be 5½ lb. The pyloric sphincter had been completely divided down to the mucosa, which was found intact and appeared healthy. There was a small amount of clotted blood around the incision in the pylorus. A catheter could be passed readily into the duodenum. There was a small area of broncho-pneumonic consolidation at the right base. All the other organs appeared healthy.

The second fatal case was three weeks old on admission and weighed 7 lb. 12 oz. Operation was performed two days later under chloroform and ether. Death occurred on the second day, signs of consolidation developing at the left base. From the time of the operation until death the child took its feeds regularly and did not vomit.

The third child was three weeks old on admission, and weighed 7 lb. 8 oz. It was noted that the face was a little drawn, the skin somewhat lax, and the fontanelle slightly depressed. Infection of the wound occurred on the second day and suppuration on the fourth day; on the sixth day the stitches gave way, and the wound gaped. Vomiting continued, and wasting set in. The child became collapsed, and died 26 days after operation. No post mortem was granted, but a limited examination of the abdomen was made through the wound. There was a large amount of pus pocketed in the lower part of the abdominal wall, and also in the lower part of the abdominal cavity, shut off by adhesions from the general peritoneal cavity. The lower part of the small gut and greater omentum were involved, and the small gut was distended and inflamed. The stomach was very hypertrophied. The incision in the pylorus was satisfactory, the mucosa being intact and healthy, and there was no sign of inflammation. It is interesting to note that in this case the skin had been prepared with ether and flavine, owing to a rise of temperature following the application of iodine four days previously.

After-results.

Of the five cases treated medically and recovering, three have been traced. In none has there been any vomiting since discharge from hospital. There has been no indigestion or abdominal pain, and the bowels are quite regular. In all three the general health has been excellent. Of the ten cases which survived operation nine are alive and well, but one child died seven months after operation.

He progressed extremely well up to the time of weaning at six months, and weighed 17 lb. He then began to vomit between feeds, diarrhœa set in, and he rapidly went downhill, dying about three weeks later. A note kindly sent from the hospital where he died stated that "on admission he was very ill; eyes were sunken, skin dehydrated, vomiting after feeds but not projectile, stools green; no abdominal tumour felt. The temperature was raised and the pulse was rapid and thready. A diagnosis of infective enteritis was made. The child did not respond to treatment, and died two days after admission. At the post-mortem examination the stomach was rather large, the pylorus thicker than normal; there was a scar ¾ in. long on the anterior surface on its lower half. On opening the stomach some milk was found, but there was no apparent contraction of the pylorus. The stomach mucosa was infected in places, and there were a few adhesions of omentum around the organ; the intestines were apparently normal in appearance."

From the history, it would appear that death was due to infective enteritis, occurring after weaning. The mother sent a photograph of an extremely healthy looking child taken two weeks before death.

The remaining nine cases are strong, healthy children. Of these, seven have had no digestive symptoms at all since the operation. One child suffers from flatulence, and has indigestion on occasions. At the time of weaning he had "bilious attacks" accompanied by vomiting. The other child had attacks of vomiting every two or three weeks for two years after operation; these were accompanied by loss of weight and constipation.

The mothers volunteered the statement that "the children were very advanced for their age," and proudly brought or sent photographs. Most of the children were breast-fed after the operation, and in all the wound had healed well and there were no herniæ. No tumour could be felt in any of the cases.

A comparison of the present weights of 13 children in the series and the weights of average male children of the same age period (Feldman[4]) shows that all except one of the children are over the average weight.

I am indebted to the physicians and surgeons of the Middlesex Hospital for permission to use the notes of cases under their care. My thanks are also due to the ward and theatre sisters for the nursing details.

CLINICAL AND LABORATORY NOTES

PROLONGED ANURIA IN A WOMAN FOLLOWING PYELOGRAPHY.

BY D. DENHAM PINNOCK, M.B. MELB., F.R.C.S.,
ASSISTANT SURGEON, LONDON TEMPERANCE HOSPITAL;
AND
I. W. MATHESON, M.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER AT THE HOSPITAL.

IT had been decided to perform pyelography to attempt to discover the cause of abdominal pain, shooting to the left side, accompanied, according to the patient (a woman of 52 years), by some frequency of micturition when the pain was severe. The pain had been troublesome for six weeks. There was no difficulty in the passage of the cystoscope or of the ureteral catheters. The bladder was normal.

Sodium iodide (15 per cent.) was used for the pyelogram; 8 c.cm. were injected into the left pelvis, which was photographed, and then this side was drained, and 6 c.cm. were injected into the right pelvis. The pyelogram showed normal pelves.

Next day the patient passed 25 oz. of urine, slightly blood-stained, and on the second day only 10 oz. were passed. From the third to the seventh day no urine was secreted. During this time she was treated by hot packs, pilocarpine injections, and purgatives; she perspired freely, and her bowels acted well. She felt well in herself until the sixth day when she complained of "heaviness." She vomited small amounts several times each day, but had no headache and was mentally quite alert. On the fifth day the right kidney became palpable. Dry cupping was performed. On the seventh day the left kidney was palpable. The bladder was catheterised on the fifth day but contained no urine. On the seventh day the blood-urea was 122 mg. per 100 c.cm. of blood. Our colleague, Dr. E. G. B. Calvert, who kindly saw the case with us, advised a venesection and accordingly 12 oz. were withdrawn about midday. That evening some six hours later some 6 oz. of urine, deeply blood-stained, were passed, followed by another 6 oz. at 9 P.M. and 4 oz. at 10.30 P.M. On the eighth day she passed 73 oz. containing much blood, and the pathological examination showed pus cells, staphylococci and *Bacilli coli communis* (not a catheter specimen). On the ninth day more than 34 oz. were passed with which was a ureteral clot of blood some 3 inches long. The blood-urea was now 157 mg.

From now she made an uninterrupted recovery, the urine became clear, and in another ten days the blood-urea had fallen to 29 mg. per 100 c.cm. blood. Throughout this time the temperature did not rise above 99·2° F. and generally was normal; the pulse-rate varied between 100 and 120 for the first three days, then remained under 100.

We are indebted to Dr. H. H. Sanguinetti for the examination of the urine and estimation of blood-urea.

THE CRITERIA OF CURE IN PULMONARY TUBERCULOSIS.

BY J. A. STRUTHERS, M.D. CAMB., M.R.C.P. LOND.,
CASUALTY PHYSICIAN AT ST. BARTHOLOMEW'S HOSPITAL; TUBERCULOSIS OFFICER TO UNIVERSITY COLLEGE HOSPITAL.

THE following cases are recorded for their interest in relation to prognosis, and to the definition of "cure" in pulmonary tuberculosis.

CASE 1.—A. B. first received treatment in June, 1922, when she was aged 13 years. Her father had recently died of pulmonary tuberculosis, and she came under suspicion on account of a cough and a mild pyrexia. When she was first examined the percussion note was found to be slightly impaired at the left apex, where also the breath sounds were harsh and a few fine râles were heard. Examination of the scanty sputum was negative for tubercle bacilli. She was sent away to a sanatorium, where the pyrexia and râles subsided in a few weeks, and whence she returned home apparently recovered in April, 1923. Her lesion gave no signs of activity during the next five years; she continued to gain in weight, was not troubled with cough, and was afebrile on every occasion but one when she was seen; on that occasion the temperature was 99° F., and she was suffering from coryza. It was thought that she might soon be considered cured. However, in May, 1928, she came up on account of a "cough following a cold," and because she also felt generally unwell. She said that she had coughed up a clot of blood.

Examination of the chest revealed the presence of râles at the left apex, and tubercle bacilli were found in the sputum. A stay in hospital, followed by six months in a sanatorium, brought about an improvement in her condition, but on her discharge tubercle bacilli were still to be found in the sputum. She remained fairly well, and was able to keep on with her work during the next 18 months, but then she began to lose ground again; there were signs of involvement of both lungs, and hoarseness and dysphonia indicated spread of disease to the larynx, in which laryngoscopy revealed unmistakable signs of a tuberculous lesion. She died in July, 1931.

CASE 2.—C. D., a magneto repairer, was aged 15 when first seen in March, 1920. On examination he was found to have signs of slight involvement of both upper lobes, some pleural friction was heard low down in the left axilla, and his sputum contained tubercle bacilli. His weight was 7 st. 5¾ lb. He gave a history of having had pleurisy on the right side three years previously. In June, 1920, he went away to a sanatorium, where he stayed until October, 1921. During this time he improved considerably; his weight rose to 9 st. 12 lb.—although, of course, normal growth accounted for some of this—and on return the lesion was apparently quiescent, as the temperature was normal, no râles were to be heard, and there was no sputum. He then returned to work, at which he remained until September, 1930.

When he was seen from time to time at the dispensary there was nothing to suggest activity of his disease, but he occasionally suffered from coryza. He complained from time to time of pain in the right hypochondrium, but this was apparently due to dyspepsia. At the end of 1926 he was told that he might consider that he had recovered, although he should still be careful in his mode of life. His weight was then 10 st. 10 lb. He was a sensible type of patient, and there is no reason to think that he behaved otherwise than carefully.

In March, 1930, he returned on account of pain on the right side of the chest, and cough. There were no adventitious sounds in the lungs, but the temperature was 99° F., and, in April, 100° F. Sputum reappeared, but no tubercle bacilli were found. By the end of April this attack had apparently subsided, he became afebrile, began to put on weight again, and went back to work. By August, 1930, his weight had risen to 10 st. 12½ lb., which was the heaviest he had ever been. At the beginning of October he suddenly had a hæmoptysis of about half a pint, and took to his bed. During the next few days there were several more hæmoptyses, and signs of broncho-pneumonia appeared, chiefly on the right side, with tubercle bacilli in the sputum. He went rapidly downhill, had several more hæmoptyses, and died on Nov. 17th. At the post-mortem examination old tuberculous lesions with multiple small cavities were found at the apices of both lungs. The pleura was thickened at both apices, and there were adhesions throughout the right pleural cavity. There was a recent tuberculous bronchopneumonic spread throughout the middle and lowest lobes on the right side, and to a slighter extent in the left lower lobe. The hæmorrhages appeared to have come from the left apex, where blood clot was found.

CASE 3.—E. F., was aged 61 when first seen in April, 1925. He was then complaining of a slight cough, which appeared to be due to chronic pharyngitis. There were signs compatible with the presence of an inactive lesion at the apex of the right lung, but otherwise, except for some emphysema, the lungs appeared to be normal. Sputum was scanty, and no tubercle bacilli were found in it. He gave a history that in 1907 he had suffered from tuberculosis of the right lung, and had had part of his epiglottis removed for tuberculous disease. After he had spent six months in a sanatorium his disease was considered to be quiescent. It was not known whether tubercle bacilli had been found in his sputum.

From then until 1918 he remained in good health, and during the war was fit enough to be employed on home service as an officer in the army. In 1918 he had an attack of "pleurisy," from which he apparently made a complete recovery. In earlier life he had been an officer in the Regular Army, had seen service in India and South Africa, and had been a good oarsman and boxer. After leaving the army in 1905 he had gone into business in the City. There was no history of any illness of any significance before 1907. In the winters of 1925–28 he had occasional pyrexial attacks, accompanied by signs of a mild bronchitis and some pharyngitis. No tubercle bacilli were discovered in the sputum, but the organisms most commonly found were *Micrococcus catarrhalis*, pneumococci, and Friedländer's bacillus.

In 1928 he had some signs and symptoms pointing to the possibility of carcinoma of the colon, but a thorough investigation of the alimentary tract failed to reveal any abnormality except colonic stasis. In October, 1929, he was suddenly seized with what was taken to be an attack of influenza. Signs of broncho-pneumonia soon appeared in both lungs; the temperature, pulse-rate, and respirations rose to 102° F., 120, and 36 respectively, and he died on the fifth day of the illness. On this occasion tubercle bacilli were found to be present in the sputum.

Prognosis in tuberculous disease is notoriously difficult; and the would-be prophet has more than once been assured on good authority that he can be certain of only one thing—that his prophecy will be wrong. The diagnosis, and even the definition of "cure," are equally difficult, in spite of all the indications given to the contrary by favourable reports on the various specifics which follow one another in endless succession through brief notoriety to obscurity. The definition officially adopted in this country by the Ministry of Health is that a patient should not be considered as cured of pulmonary tuberculosis until five years have elapsed without any manifestations of active disease. Experience—as witnessed by the first two cases here recorded—shows this definition to be none too stringent. A definition which suggests itself as theoretically admirable—though of doubtful practical value—is that the term "cured" should be applied to the patient who attains the normal expectation of life from the beginning of the quiescent period. Perhaps, in view of the third case recorded above, the only safe prognosis is a variant on that favourite reflection of the Greek dramatists on the insecurity of human happiness—Call no man cured until he is dead.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

SECTION OF MEDICINE.

At the second session of this section Dr. A. Deane (Vice-President) took the chair, and a discussion on

Varieties of Secondary Anæmia and their Treatment

was opened by Dr. L. J. Witts. Analysing the causes of secondary anæmia he emphasised the importance of a group of cases occurring chiefly in women of reproductive age in which none of the usual causes was present, and which formed a distinct clinical entity for which he suggested the name of chronic microcytic anæmia. Twenty-six per cent. of the cases of anæmia admitted to Guy's Hospital during a three-year period he had found to belong to this group, 86 per cent. of these occurring in women. A study of the age-incidence showed a steady increase to a maximum between the ages of 40 and 49, and then a sudden fall. Individual cases might show spontaneous improvement after the menopause. Age- and sex-incidence were, therefore, different from those of pernicious anæmia and achlorhydria. Women affected were found in all classes of the community, but they often showed signs of an asthenic diathesis and gave a history extending back into childhood of intestinal dyspepsia and nervous instability. Clinically, the group was characterised by an anæmia with low colour-index, about 0·5, showing red cells with a diminished diameter and slightly increased fragility. The van den Bergh reaction was negative, the bilirubin and free iron content of the plasma being diminished. The spleen was palpable in one-third of the cases. The bone-marrow showed a normoblastic hyperplasia which on treatment gave way to normal red cell production. Achlorhydria was present in 81 per cent. and glossitis in at least 50 per cent. of cases. These inflammatory changes in the mouth sometimes extended back into the pharynx causing dysphagia. A spoon-shaped deformity of the nails was also common.

The condition, he found, was most likely to be confused with splenic anæmia. The latter, however, was seen commonly in young adults, and showed greater splenic enlargement, while the patient might give a history of jaundice and hæmorrhage. The fingers also showed slight clubbing as opposed to the spoon-shaped nails so characteristic of chronic microcytic anæmia. The frequency of achlorhydria which, as far as his evidence went, was present before the anæmia developed led him to emphasise its possible importance in the ætiology of the disease. He had found massive doses of iron by mouth extremely effective in treating the anæmia. Small doses of iron or injections of iron were useless. He regarded grs. 60 of iron ammonium citrate or grs. 30 of Blaud's pill as minimum doses. Treatment had often to be continued for three months with these large quantities in order to reach a hæmoglobin of at least 80 per cent. and small doses in many cases had to be given indefinitely to prevent relapse. Transfusion was temporarily effective but relapse always followed, and unexplained fatalities might occur in spite of careful direct matching of the blood. Liver, liver extract, desiccated stomach, hydrochloric acid, and splenectomy he had found valueless.

Prof. Stanley Davidson reported satisfactory results in treating a miscellaneous group of cases with large doses of iron. It had been possible in one case of carcinoma of the colon to bring the hæmoglobin level back to normal, and he treated all cases of secondary anæmia associated with new growth intensively with iron for three weeks before operation, raising the hæmoglobin 30 per cent. in this way.

Dr. Janet Vaughan classified secondary anæmias as deficiency diseases dependent upon the lack of those substances essential for normal blood production—i.e., an adequate supply of iron, two factors present in whole liver, one of which was also present in liver and stomach extracts, vitamin C and a factor probably associated with the vitamin B complex. The deficiency might be brought about by faulty diet, failure of absorption or digestion in the alimentary canal, or excessive loss from the body. She quoted her own and other observers' cases to show that idiopathic microcytic anæmia, anæmia secondary to acute and chronic hæmorrhage, and the simple anæmia of infancy responded well to massive iron dosage. She showed that anæmia secondary to chronic hæmorrhage, starvation, deficient dietary in children, past sepsis, and carcinoma was relieved by whole liver combined with adequate iron, anæmia in association with scurvy by vitamin C. The anæmia of chronic myeloid leukæmia had been improved by large doses of arsenic. She emphasised the necessity of adequate dosage of iron and liver, suggesting that Blaud's pill should be given in powdered form to ensure utilisation; grs. 60 of Blaud's pill and ½ lb. of liver a day being minimum rather than maximum quantities. Liver extracts, stomach extracts, and the factor associated with the vitamin B complex had only been found of value in treating macrocytic anæmias.

Prof. H. F. Moore described a series of cases of idiopathic microcytic anæmia which reacted well to massive iron therapy. He had found achlorhydria common in both diabetes and hyperthyroidism.

In the ensuing discussion Dr. A. V. Clarke said he had found insulin, 20 units twice a day, in conjunction with glucose, valuable in treating severe anæmia. One case of pernicious anæmia unable to take liver or ventriculin had responded to raw beef incubated with gastric juice. Dr. George Graham emphasised the value of ferrous as opposed to ferric salts. Dr. E. P. Poulton said that Dr. A. F. Hurst had been the first person to appreciate the value of massive iron therapy in this country. Dr. Frewen Moor had found ultra-violet light valueless unless the anæmia improved after the first three applications. Dr. R. C. Hutchinson mentioned a case of obstinate varicose ulcer which healed after he had given iron for the associated anæmia, and also a case of high blood pressure associated with anæmia when the blood pressure fell to normal on recovery. Dr. John Eason considered that anæmia associated with syphilis responded well to antisyphilitic treatment. He believed many cases of chronic microcytic anæmia were associated with hypothyroidism. Dr. William Russell as early as 1880 had given as much as grs. 180–200 of Blaud's pill with satisfactory results. Dr. R. A. Young instanced cases where small doses of copper gr. ⅛ had improved the anæmia. Dr. Rupert Waterhouse asked if there was any knowledge of variations of blood volume in secondary anæmias. Prof. A. Rabinowitz (New York) said he had found severe anæmia in acute nephritis associated with œdema and in chronic nephritis associated with nitrogen retention. The latter was sometimes macrocytic in character and responded well to liver therapy.

In reply, Dr. Witts mentioned two cases of simple achlorhydria anæmia which had progressed to pernicious anæmia and one in which the reverse had occurred. He had found the ferrous salts ten times as effective as the ferric salts and that iron in pregnancy anæmia was not always of value. None of the cases in his series had shown signs of myxœdema, the basal metabolic rate being normal. The incidence of microcytic anæmia was, in his opinion, unaffected by environment. He did not believe there were any reliable data concerning blood volume changes in secondary anæmia.

SECTION OF DISEASES OF CHILDREN.

At the third session of this section, the chair was taken by Dr. E. H. Rainey, and a discussion on the recognition and treatment of

Birth Injuries in the Newly Born

was opened by Prof. G. B. Fleming. While emphasising the remarkable recuperative powers of an infant suffering from the traumas of birth as contrasted with its poor resistance to infection, he pointed out that apparently about 30 per cent. of all neonatal deaths were due to birth injury. His paper was based on 350 cases of birth injury among approximately 8000 consecutive infants born alive at the Royal Maternity Hospital, Glasgow. He proposed to devote his remarks only to two groups of cases. Injuries of the infant's *skin and subcutaneous tissues* occurred even in normal labour, and sloughing or infection might cause trouble when the damage to these tissues was more severe. Cellulitis was not uncommon in breech presentations with much bruising and œdema. Injuries to the *nervous system* were the most serious of birth injuries and the most likely to leave permanent disability, though here again the infant's recuperative powers were remarkable. Injuries to the peripheral nerves other than the facial (66 cases in the series) and the brachial plexus (28 cases) were rare; injuries of peripheral nerves of the lower limb might be extremely difficult to differentiate from damage to to spinal cord. Rapid recovery in one to two weeks was the rule in facial paralysis. The early recognition and treatment of brachial paralysis was important, for the earlier the treatment the better the result. Till a satisfactory splint was made the affected limb should be fixed to the pillow with a piece of adhesive plaster round the wrist and a safety pin, the arm being suitably abducted and externally rotated, and the forearm flexed to a right angle and supinated. In very few cases was an attempt at nerve suture advisable. Injury to the spinal cord was commonly produced during breech extractions, and in fatal cases it was usually unrecognised. If the child survived, the symptoms were those of a transverse myelitis. Intracranial hæmorrhage was extremely common; Cruickshank in 800 neonatal autopsies found gross hæmorrhage in 20 per cent. It was extremely difficult to diagnose with certainty during life, but signs pointing to the condition were drowsiness, feeble cry, inability to suck, muscular rigidity, convulsions, bulging fontanelle, and intermittent cyanosis. Dr. Fleming considered that a definitely pigmented or uniformly blood-stained cerebro-spinal fluid with crenated blood-cells was probably the most important manifestation available, but did not afford absolute proof. The fluid should be centrifuged as soon after withdrawal as possible to note any yellow pigmentation. Treatment should be symptomatic: careful nursing, and feeding with the stomach-tube if necessary; if there was increased intracranial pressure lumbar puncture, or in some cases where intraventricular bleeding was suspected, ventricle puncture was required. For convulsions chloral hydrate gr. 1 might be given two-hourly. In 33 cases followed up by Dr. Fleming and Dr. E. D. Morton for a year or more, five were mentally deficient: of these, four had spasticity of one or more limbs, one had spastic diplegia, and one hydrocephalus.

Dr. N. B. Capon welcomed the choice of birth injuries as a subject for discussion at the section, for it showed that the care of the new-born child was coming into the domain of the pædiatrician. He believed that this would give the infant a better chance, for the obstetrician must of necessity be preoccupied with the mother rather than with the child. The appointment since the war of pædiatricians to the staffs of some maternity hospitals was an important advance. Public attention was at present concentrated on the maternal death-rate, but though the maternal deaths in England and Wales in 1929 were 2787, the deaths of infants in the first month of life numbered over 21,000, and probably over 7000 of these babies suffered from birth injuries of one sort or another. Of the fatal cases of intracranial trauma nearly half had no gross hæmorrhage, and death appeared to be the result of congestion, concussion, or œdema. The clinical differentiation of these different types of trauma had up to now proved very difficult, though the prognosis was not the same. If there was no hæmorrhage and recovery occurred, it would probably be complete; with hæmorrhage there might be after-effects such as hemiplegia or other evidence of permanent damage to the brain, though here again the majority of survivors appeared to be normal. In the differential diagnosis between intracranial trauma and such varied conditions as inanition fever, pneumonia, poisoning through maternal toxæmia, and congenital abnormality of the brain, attention should be directed to the following points: the type of labour, whether the infant is immature, whether the infant shows cyanosis or pallor, failure of the sucking reflex, character of respiration, and abnormal somnolence or excessive crying. The prevention of trauma was a problem for the obstetrician, treatment concerned the pædiatrician. Whether or not lumbar puncture should be done in any individual case was difficult to decide, since on the one hand these infants were often in a state of surgical shock and harm might be done by puncture, and on the other a case of excessive intracranial pressure would die if unrelieved, and the state of the fontanelle did not give the guidance one might expect. He himself used in the past to do more punctures than he now did.

Dr. A. Bennett agreed about the frequency of intracranial hæmorrhage, but pointed out that the small hæmorrhages discovered post mortem were very often not the cause of death. She suggested the desirability of giving intramuscular citrated blood injections. Dr. Donald Paterson and Dr. H. M. M. Mackay further discussed the difficulties in the diagnosis of intracranial trauma, and also advocated the more extensive trial of intramuscular injections of blood at as early a stage as possible. Dr. C. F. Harris inquired whether Prof. Fleming had tried increasing the carbon dioxide intake, combined with extra oxygen, in cases of difficult breathing. If the respiratory centre was injured this method of stimulation of the centre might tide the infant over the first few critical days. Dr. A. A. Moncrieff had been experimenting on animals with carbon dioxide and lobeline for the stimulation of respiration, and considered both agents valuable in the cases under discussion.

Prof. **FLEMING** replying said he had not seen harm result from lumbar puncture in cases of birth injury. He was against stimulating a damaged respiratory centre by the administration of extra carbon dioxide.

Congenital Pyloric Stenosis.

Mr. C. **MAX PAGE** gave an account of pyloric stenosis from the surgical standpoint, with details of the operative procedure he employed. He considered the medical pre- and post-operative treatment of primary importance, but found that drugs had little influence on the outcome. He pointed out that though in this country Rammstedt's operation was accepted as the treatment giving the best results, exclusively medical treatment was still widely used abroad without operation, and in one large series treated the mortality was only 14 per cent. Among complications of surgical treatment were: infection of the wound, recurrent vomiting—which should be rare if the operative division at the pylorus was satisfactory—hyperpyrexia, broncho-pneumonia, and gastro-enteritis. In 60 cases operated on by Mr. Page at the Victoria Hospital for Children, the mortality was only 6·6 per cent., whereas with the same operation and, so far as he could determine, the same treatment at St. Thomas's his operative mortality was approximately double.

Dr. **NOAH MORRIS** gave the biochemical findings obtained by Dr. Graham and himself. In pyloric stenosis, he said, there was an alkalosis with increased blood bicarbonate, and decreased chlorine in the blood and the urine. This alkalosis might occur even if there was no vomiting with the consequent loss of chlorine in the material ejected from the stomach. Correlated with the alkalosis there was depressed and slow respiration. During recovery after operation the carbon dioxide in the blood fell to normal. He suggested that the chlorine in this disease might be largely in organic combination and not combined with a base. His conclusions as regards treatment were that saline solution should be given to supply chlorine, but should not be continued until there was œdema, since this was associated with excessive retention of chlorine; that alkalis should not be given either in the form of citrates or an alkaline stomach lavage, and that if the breathing was slow and depressed a local anæsthetic should be used in preference to a general.

Dr. **PATERSON** described two unusual cases. In the first, which strongly suggested that hypertrophy of the pyloric muscle occurred during intra-uterine life, a premature baby, born at least one month before term, died ten days later with well-marked hypertrophy of the pylorus. In the second case the infant, died at 8 months old, still with symptoms of pyloric hypertrophy and stenosis, although there had been periods of remission. He pointed out that symptoms usually disappeared spontaneously in babies that survived for 16 weeks. He quoted mortality statistics derived from a series of about 600 cases. The mortality at Great Ormond-street Hospital was roughly about 1 in 4; among 24 cases operated on in private practice there was a mortality of 8 per cent., and in a series of 36 cases treated in one large nursing home there had been not one death. He attributed the great difference in mortality between hospital cases and private cases to the difference in amount of nursing care available for each baby, since the private case had at first a day-nurse and a night-nurse whose whole time was given to its care; and secondly to the fact that in hospital there was always the risk of infection from other children. He outlined his routine post-operative treatment, emphasising the importance of breast milk whenever possible. He advocated operation in all cases of pyloric stenosis when the baby was not gaining weight, unless it was already over 12 weeks old, as at about this age spontaneous recovery might be expected. No cases of hyperpyrexia occurred if atropine was not given.

Dr. **DOYNE BELL** indicated the danger of too great reliance on radiographic diagnosis in this condition. He had proved that the idea that first-born babies are especially liable to pyloric stenosis was a fallacy. Unlike Dr. Paterson he used very dilute feeds in his post-operative treatment.

Dr. **JEAN SMITH** corroborated Dr. Morris's findings. The biochemical changes, indicating an alkalosis found in pyloric stenosis were useful in distinguishing this condition from vomiting due to other causes if the clinical findings were not conclusive. If the alkali reserve was not diminished, say in two days, by the administration of saline and glucose, operation should not be further delayed, as such cases do badly on medical treatment.

Mr. **R. A. RAMSAY**, like Dr. Paterson, advocated local anæsthesia for the operation, and considered a palpable pyloric tumour was of fundamental importance in establishing diagnosis.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

AT the first session of this section, with Sir **JAMES PURVES-STEWART**, the President, in the chair, a discussion took place on

Cerebral Hæmorrhage Due to Other Causes than Arterio-sclerosis.

Dr. **JAMES COLLIER** pointed out that our knowledge and successful treatment of the condition had been greatly increased during recent years, chiefly owing to lumbar puncture and its almost universal application in cases presenting a picture of meningitis, of coma, of apoplexy, or of unexplained headache, and in the routine examination of the cerebro-spinal fluid in disease of the nervous system. The following list comprised the main causes of this type of cerebral hæmorrhage: injury during birth or following concussion, hæmorrhagic pachymeningitis, encephalitis, poliomyelitis, encephalitis lethargica, tuberculous meningitis, sinus thrombosis, abnormal blood states (e.g., leukæmia), anthrax infection, neoplasms, and various aneurysms, such as (*a*) infective, as in ulcerative endocarditis, (*b*) occurring in coarctation of the aorta, (*c*) occurring in polyarteritis acuta nodosa, and (*d*) the berry-like and often multiple aneurysms which have been termed congenital aneurysms. The three most important of these, however, were encephalitis, neoplasms, and cerebral aneurysms.

Many cases of encephalitis which had been confirmed histologically had been complicated by subarachnoid and cerebral hæmorrhage. Encephalitis lethargica was also of interest in connexion with the subject, for many cases of subdural, subarachnoid, and cerebral hæmorrhage from ruptured aneurysms had been recorded in which the clinical picture was hardly distinguishable from that of this type of encephalitis. Neoplasms of soft texture were also important causes of cerebral hæmorrhage, for such a growth might bring on a hæmorrhage even before the appearance of any local or general signs of tumour. Dr. Collier wished, however, to devote most of the time at his disposal to the subject of cerebral aneurysms. Such aneurysms were held to be of common occurrence, and often gave rise to no trouble during life, since at least one-fifth of the numerous specimens in museums had been chance discoveries at necropsy. They were never syphilitic in origin; the minority were due to bacteriological infections of the blood, such as in infective endocarditis, gonococcal and puerperal infections. In coarctation of the aorta, where the arterial tension above the constricted area in the aorta became extremely high when adult life was reached, the tunica media spread locally under the pressure with the formation of aneurysms, which were often multiple. They were also a feature of the curious malady first described by Kussmaul—polyarteritis acuta nodosa. The cause of the majority of the cerebral aneurysms had not yet been determined with certainty. Eppinger had termed them "congenital aneurysms," implying that they were due to a local congenital defect in the arterial wall. These aneurysms seemed to give rise to no symptoms unless they clotted up, calcified, or became adherent to surrounding structures—usually to some of the cranial nerves—or unless they ruptured. They might rupture in any situation within or upon the brain; they then produced the syndrome of a rapidly severe apoplexy, with blood in the cerebro-spinal fluid. These aneurysms had a tendency to rupture slightly and to leak slowly, after which they often healed only to leak again later on—sometimes in another situation. They might leak into the subdural space, and there form an organising hæmatoma, with a clinical picture sometimes resembling encephalitis lethargica. They often leaked into the subarachnoid space, and then most commonly produced a syndrome precisely resembling meningitis; the distinction from the latter condition was the presence of blood in the cerebro-spinal fluid and the relief produced by draining. The transient phenomena which might follow on a not too rapid and not too copious hæmorrhage upon or within the brain were very remarkable, and some of them were likely to give rise to difficulty in diagnosis, as they might occur without headache or signs of meningeal irritation. The more common of these transient signs were attacks of unconsciousness, lasting from a few hours or many days, headache resembling migraine, hemiplegia, aphasia, convulsions, delirium, pyrexia with headache, unconsciousness with albuminuria or glycosuria. The following was a short list of the regions in which an aneurysm might burst or leak: (1) transdural rupture—aneurysm of the posterior communicating artery; (2) subdural rupture; (3) subarachnoid rupture; (4) intracerebral rupture, either from a surface aneurysm, which became adherent to the brain tissue or from an aneurysm buried in the brain tissue; (5) primary rupture into the ventricle; (6) rupture of an internal carotid aneurysm into the cavernous sinus—the clinical picture being that of a unilateral pulsating aneurysm.

The treatment of subarachnoid hæmorrhage was an interesting matter for discussion, since it had been held that the repeated draining away of the effused blood in lumbar puncture increased the tendency to bleeding, though it undoubtedly relieved the symptoms for the time being. Dr. Collier's practice was always to drain freely and repeatedly so long as the symptoms of increased intracranial pressure persisted, and he had never had cause to regret this practice.

DISCUSSION.

Prof. A. J. Hall limited his remarks to subarachnoid hæmorrhage. There were several interesting features in these cases to which he would call particular attention. (1) Occasional massive albuminuria. In one of his cases in which this condition was present the kidneys were found to be normal on post-mortem examination. (2) The occurrence of Korsakow's syndrome during recovery. Although the symptoms might persist for several weeks, recovery was the rule. (3) The frequency of slight or severe exacerbations after the initial hæmorrhage. This might occur owing to the true nature of the illness not being recognised at first and complete rest not being insisted upon; on the other hand, it might also occur with the patient at complete rest in bed. (4) The occasional occurrence of convulsions during recovery. Sometimes a sudden muscular effort might determine the moment of leakage, but in others the precipitating factors were so slight as to justify the term "spontaneous hæmorrhage." Dr. Hall then cited, in illustration, certain cases of intracranial aneurysm resulting in hæmorrhage. There was also an important medico-legal aspect, in that if the leak was initiated by some strenuous act during the course of employment, or a blow, as when boxing, what should be one's attitude in assessing compensation, or in attributing the result to the blow?

Dr. W. J. Adie stated that the symptoms of subarachnoid hæmorrhage might appear without evidence of previous ill-health in patients with polycystic kidney and infective endocarditis. He thought that aneurysms leaked most often in warmer weather, and in several of his cases a diagnosis of "sunstroke" had previously been made. Premonitory headaches, resembling migraine, were common, and might occur at intervals for many years; in their most characteristic form the hemicrania was always on the same side of the head. Retinitis proliferans sometimes yielded evidence that an aneurysm had leaked in the past, and gave the clue to the cause of the symptoms in a later attack. He had also seen bilateral hæmorrhage into the vitreous, and also three cases in which herpes zoster was a complication. Recovery from the mental symptoms resembling Korsakow's syndrome was always complete.

Mr. Hugh Cairns discussed the surgical treatment of intracranial hæmorrhage, and described cases both of subdural and intracerebral hæmorrhage which had been treated successfully by operation. He emphasised the importance of small bilateral subdural explorations under local anæsthesia in every case in which subdural hæmatoma was suspected. A subdural hæmorrhage might not necessarily be localised, and might resemble a subarachnoid hæmorrhage, blood trickling down subdurally into the spinal canal, and even yielding pure blood on lumbar puncture. Mr. Cairns also described a case in illustration of the good result that could be obtained from the removal of large blood clots from within the brain itself.

Dr. J. Purdon Martin confined his remarks to hæmorrhage in relation to the dura mater. Widespread subdural hæmorrhage might be a sequel of head injury without any fracture of the cranium; it might prove fatal, or give rise to chronic subdural hæmatoma. The localising signs of the latter were often vague and deceptive. Often the blow causing the injury appeared trivial, especially in elderly subjects, and might consist merely in jerking the head. There was often a latent period of weeks or even months, or only vague and indefinite symptoms before signs of cerebral compression made their appearance. Sometimes the extravasated blood did not clot, but appeared to suffer defibrination.

Dr. J. G. **Greenfield** considered only that form of cerebral aneurysm which had been called "berry aneurysms." In his experience these aneurysms had been found most frequently in the arteries of young or middle-aged subjects who had shown either no trace of atheroma or only small isolated plaques. An abnormal arrangement of the cerebral or systemic arterial system had been commonly described in patients dying from ruptured intracranial aneurysm, a fact which constituted one of the grounds for considering a congenital malformation of vessels as the cause of these aneurysms. In an important paper published in November, 1930, Wiley Forbus had given a clear description of the true defect. He had shown that it was primarily a defect in the muscular coat of the artery rather than in the elastic coat, and had demonstrated its presence not only at the point where the aneurysm formed, but at practically every bifurcation of the cerebral vessels in these subjects. He had demonstrated such a defect also in the mesenteric vessels. Dr. Greenfield had examined the cerebral arteries in five non-atheromatous cases of cerebral aneurysm, and had found this defect present in all, whereas it was not present in two cases of intracerebral hæmorrhage of the atheromatous type. As regards treatment, the value of drainage of cerebro-spinal fluid in cases of subarachnoid hæmorrhage had been stressed by Dr. Collier, but there were some who were still opposed to this procedure on theoretical grounds, holding that reduction of intracranial pressure removed some support from the outer surface of the aneurysms. This theory had been proved to be fallacious by new knowledge on the relationship between the intracranial arterial pressure and the general intracranial pressure. Baillard and Magidot had demonstrated the fact that the pressure in the intracranial arteries rose and fell with raising and lowering of the general intracranial pressure. It had been known since the work of Cushing that rises in the general intracranial pressure up to the normal diastolic blood pressure did not cause any rise in the latter as measured in the brachial artery. But such rises automatically caused corresponding rises in the cerebral arteries, so that, whereas the pressure in the retinal artery was normally 50 per cent. of that in the brachial artery it rose to 60 or 90 per cent. of it with increase of intracranial pressure. Berens had also shown that, in even so small a branch as the retinal artery, the systolic pressure is from eight to ten times the general intracranial pressure as measured by the lumbar puncture manometer. It was therefore evident that: (1) the rise of intracranial pressure which was caused by rupture of a basal aneurysm automatically raised the blood pressure within that aneurysm, and was therefore likely to cause further bleeding; (2) that reduction of the general intracranial pressure by drainage of cerebro-spinal fluid would automatically reduce the pressure inside the aneurysm to a far greater extent than it would remove support from outside it.

Mr. A. A. **McConnell** described a case of subdural hæmatoma in a man aged 70, in whom headache appeared two days after jerking the head. In the course of a week focal symptoms—paresis of the left arm and leg—made their appearance. At no time was consciousness impaired, although cerebration was slow. Operation revealed a definite subdural hæmatoma, and the patient made a good recovery.

(Continued at foot of next column.)

(Continued from previous column.)

Mr. **Astley Clarke** mentioned hilarity as an early and almost only symptom in a male case, aged 24, of aneurysm of the basilar artery, which ruptured and caused death. He had also seen two other cases in females, in whom laughing of an unusual character was observed as an early symptom in similar intracranial hæmorrhage.

Dr. **Hinds Howell** emphasised the frequency with which subdural hæmorrhages were bilateral, and cited an instance in a man aged 60. Following what at first appeared to be a mild head injury, left hemiplegia developed after six weeks. Operation was performed on the right side, and a large subdural hæmatoma was found and evacuated. The patient improved for 24 hours, after which he relapsed into a semi-comatose condition. The operation area was re-explored, as it was thought that further hæmorrhage might have occurred. Nothing was found, and it was hoped that the compressed brain still remained unexpanded. The patient died on the following day, and autopsy showed another subdural hæmatoma on the opposite side. The speaker had seen cases of subarachnoid hæmorrhage with massive albuminuria similar to those described by Prof. Hall, and there was an obvious danger of making a preliminary diagnosis of uræmia. In association with the albuminuria, glycosuria and acetonuria might also occur.

PLASMOQUINE IN MALARIA.

A REVIEW OF RECENT EXPERIENCES.

Plasmoquine, the trade name for N-diethylamino-isopentyl-8-amino-6-methoxy-quinoline, was introduced into the therapeutics of human malaria in 1926, and for five years workers in various parts of the world have been testing its uses and limitations.

The Army in India.

There is no organised body of men whose efficiency has been more handicapped by malaria than the British Army serving in India. Accurate statistics of the morbidity from this cause have been kept over a long period, so that it has become possible to estimate the value of any form of antimalarial treatment with greater degree of accuracy amongst soldiers under continuous and disciplined observation than amongst a similar body of civilians. An exhaustive trial in India of plasmoquine and quinine has recently been reported [1] by Major J. A. Manifold in the treatment of benign tertian malaria, the form of malaria most prevalent amongst serving units and most detrimental to service. In this paper Major Manifold has drawn on the accumulated experience of 325 publications on this subject which have appeared lately. From a study of these it has been realised that many of the untoward symptoms hitherto described were due to the slender margin between the therapeutic and toxic doses of plasmoquine. Sinton, Smith, and Pottinger *having in 1930* reported unfavourably on a daily dose of 0·06 g., it was resolved *to try 0·04 g. plasmoquine plus* 1·25 g. (grs. 20) of quinine taken for 21 consecutive days. The troops concerned in mass treatment included both British and Indians, the latter varying greatly in physique. *The experiment being spread* over such a huge area of country with varying degrees of humidity and temperature, the conditions varied enormously. *In most* stations it was quite impossible during the malaria season to discriminate between fresh cases of malaria and relapses. Any attempt to take into account different factors by varying the dosage of plasmoquine was obviously impracticable; no difference was made in the dosage used for individual cases and any fresh attack within six months of completion of treatment was considered as a relapse. By entrusting the treatment however to a large number of medical officers in different parts of India many individual results and opinions could be obtained. Sufficient plasmoquine was available to treat 4000 cases, and in each command certain officers were selected to undertake the treatment and to keep records of the cases treated. In stations in which a laboratory was situated the medical officer carrying out the treatment worked in close coöperation with the officer in charge of the laboratory.

---

[1] Jour. R.A.M.C., May–June, 1931.

The treatment of all cases of benign tertian malaria consisted of one tablet containing 0·02 g. plasmoquine combined with grs. 10 of quinine in the morning and a similar amount in the evening, the total course of treatment being 21 days. In all, 3187 cases (1286 British, 1901 Indian) of benign tertian malaria completed this course and are included in the analysis. Cases treated after Dec. 31st, 1929, and subtertian cases treated partially with quinine and subsequently with plasmoquine were not included. A special watch was maintained for toxic symptoms and precise instructions having been issued regarding their nature. In the great majority of instances these symptoms were never severe and frequently were not mentioned in the hospital register after the first 20–30 cases had been treated. The effects of suggestion, particularly as regards "colic," could not be neglected for it was noticed that once patient and medical officers had gained confidence in the drug, complaints became fewer and eventually ceased altogether. As a corollary to this the larger the number of cases treated in a hospital, the more favourable the opinions expressed on the value of the treatment and the fewer were the toxic symptoms of real importance noted—a statement which tallies with the experience of other workers both here and in the tropics.

TOXIC SYMPTOMS.

The percentage of toxic symptoms recorded, such as abdominal pain, cyanosis, and digestive disturbance was less amongst Indian than amongst British patients, owing no doubt to the greater attention paid to mild symptoms. In view of the fact that 99 per cent. of all the cases ultimately completed their course of treatment, toxic symptoms cannot have been severe. Abdominal pain constituted the one constant complaint; it was found to occur with less frequency when the drug was taken on a full stomach or with a large draught of water. The incidence of this pain definitely increased with the duration of the treatment indicating, as had already been realised, that plasmoquine is a cumulative drug showing its maximum effects on about the sixth day of treatment. Epigastric pain occurred as a rule within a few days of beginning the course and disappeared quickly on temporary cessation of plasmoquine administration. In this series of cases cyanosis is recorded as having been noted in 4·3 per cent. of British and 0·67 per cent. of Indians. The lower proportion amongst the latter group is probably accounted for by the difficulty of recognising it in dark-skinned races. As previously noted by Fischer and Weise the cyanosis becomes evident clinically about the seventh day and it appears also to occur with greater frequency in anæmic cases and is accompanied usually by epigastric pain. Many cases appeared to lose their pink complexion during treatment, but yet could not be called actually cyanosed. It seems then that in a small percentage of cases there does exist a definite individual idiosyncrasy to the action of the drug with reference to epigastric pain and cyanosis. In the average case of cyanosis a continuance of the treatment does no harm and the methæmoglobinæmia does not increase.

Opinions were much divided as to the effect of the treatment in the reduction of chronic enlargement of the spleen; only in acute enlargements is it effective in reducing the organ to normal size. As regards the pyrexia it was found that on the whole patients responded more rapidly to treatment with plasmoquine and quinine than to quinine alone, and in no case was it necessary to give intravenous or intramuscular quinine. Relapse is the crux of efficient treatment and out of this trial the test has emerged triumphant. The relapse-rate was surprisingly small, the average for all classes and stations being 5·2 per cent. If cases relapsing after what may be roughly called the end of the malaria season in the various stations only were accepted as relapses, then the relapse-rate would be as low as 2·4 per cent. The figures for the relapse-rate are definitely favourable as compared with the usual quinine treatment. In the quinine-treated control series of Sinton, Smith, and Pottinger at Kasauli the relapse-rate was as high as 42 per cent.

There were two deaths amongst the Indian cases. The first occurred after vomiting and was not considered to be due to plasmoquine treatment; the second appears to have been due to blackwater fever (methæmoglobinæmia) and it is possible that it was a case of mixed injection with benign and subtertian malaria. There were two other cases of mild methæmoglobinæmia which recovered; they may have been mild cases of blackwater fever more likely than instances of toxic plasmoquine methæmoglobinæmia.

The report closes with quotations from various medical officers in the I.M.S. and R.A.M.C. On the whole the opinions were favourable and encouraging. The efficacy of this treatment combined with simplicity of administration and shortness of course appealed to both medical officers and troops. Most questions on this important subject having been satisfactorily answered it remains to be ascertained whether plasmoquine can be safely issued to patients not under medical supervision. The answer would appear to be definitely in the negative, but if the margin of safety can be made greater and good results obtained by utilising 0·03 g. plasmoquine as a daily dose plus quinine (grs. 20) for 21 days, a definite advance would be made. Investigations on these lines are being carried out at the malaria treatment centre, Kasauli. There 57 cases have been treated up to date. Toxic symptoms have been non-existent and the patients have been able to play an occasional game of hockey or football.

Central America.

Three other reports of importance are before us. The staff of the United Fruit Company have been assiduous in recent years in investigating plasmoquine treatment. In the nineteenth annual report of the company's medical department, Dr. N. P. Macphail writes on plasmoquine as an aid in malaria prevention in Guatemala. The conclusions arrived at as the result of the administration of 1,388,000 tablets of plasmoquine were as follows: Plasmoquine effectively destroys the gametocytes of all forms of malaria when given in doses of 0·03–0·04 g. daily for one week. Combined with quinine, plasmoquine is a safe and sure way of preventing the formation of gametocytes during an attack of malaria; and the combination destroys all types of parasites. Toxic symptoms need not be feared when the dosage is limited to 0·03 g. daily for a week or more. It is considered that there is ample clinical proof to justify the hypothesis that plasmoquine is of importance as a curative factor in chronic cases which have resisted extended efforts at eradication with quinine and arsenical preparations.

Dr. Vincente Bustillo, at Banes, Cuba, has come to much the same conclusions. The doses of plasmoquine in his practice are much smaller and consist of one plasmoquine tablet (0·01 g.) for four days and grs. 20 of quinine. Children under 5 years of age received 0·005 g. for eight days and no untoward effects with the dosage above mentioned have been noted. Since 31 out of 34 cases showing crescents in the blood became negative within nine days subsequent to the initiation of plasmoquine treatment, it can be concluded that the doses used were sufficient to cause a disappearance of gametocytes from the peripheral circulation from one to eight days in 91 per cent. of the cases and within nine to twelve days in the remaining 9 per cent. The easy disappearance of gametocytes leads to the belief that plasmoquine has a direct action upon them; but it is probable that they are devitalised to be afterwards destroyed by phagocytoses.

In assessing the rôle of plasmoquine in the sanitation of Panama, O. T. Brosius exercises due care in the field of its application. Working with a force of employees totalling some 4800 the difficulty of gauging the value of "blanket treatment" with plasmoquine and quinine may be imagined. The conclusions arrived at are that plasmoquine has probably played a more active rôle in effecting a reduction in malaria infections than was given credit for in earlier attempts to determine its exact value in tropical sanitation. It is emphasised that with a distinct reduction in malaria, there was a simultaneous decrease in the hospital admissions, which was more or less in direct ratio to the malaria decline. In a community such as Panama with a comparatively limited turnover in the labour force by sufficiently frequent plasmoquine and quinine blanket treatments the sterilisation of the gametocytes to malaria carriers can be repeated at given intervals.

The Present Position.

It is evident from the information summarised above and the publication[2] of the prophylactic experiments of S. P. James and his co-workers that the whole question of plasmoquine has entered a new phase. The progress so far achieved has been satisfactory, but a less poisonous compound than plasmoquine would undoubtedly lead to greater confidence in its extended usage away from medical supervision, and it is much to be hoped that in the future less toxic compounds will be found. More information is needed about the effect of administering plasmoquine under all sorts of conditions. Recent work has confirmed in a striking manner the accuracy of the pioneer observations made with a limited series of cases at the Tropical School in Hamburg, and subsequently at the Hospital for Tropical Diseases, London.

REVIEWS AND NOTICES OF BOOKS

Heart Disease.

By PAUL DUDLEY WHITE, M.D., Instructor in Medicine, Harvard Medical School; Physician, Massachusetts General Hospital, Boston. London: Macmillan and Co., Ltd. 1931. Pp. 931. 42s.

Dr. Paul White's book is the most comprehensive treatise on cardiology which has appeared in the English language in recent years. It touches on every aspect of the subject, from the most important to the most trivial, and therein lies its chief defect—namely, a lack of perspective. There is too much detail, too little emphasis on some of the main points. To deal adequately with all the subjects to which the author refers would require a book of at least twice this size, and it is doubtful whether any one cardiologist would be competent to write such a book. Possibly this criticism will be less pertinent for the American than the English reader, for there is a wide difference in the outlook on medicine in the two countries. In America the investigation of clinical cases follows a more universal plan than in Britain; every fact is carefully recorded in the case-notes, with the result that sometimes it appears to us difficult to sort out the capital matter. With us the investigation of cases is less systematic. Our idea of a great clinician is a man who can pick out the essential points of a case and give his undivided attention to them alone, discarding everything which is irrelevant. The great teachers of medicine in this country have impressed on the minds of their students vivid pictures of individual cases in the wards. This difference of viewpoint is strikingly illustrated by Dr. White's book. He refers occasionally, it is true, to the occurrence of particular symptoms in patients in his own practice, but from beginning to end his treatment of the subject is strictly systematic.

The book is divided into four parts, which deal respectively with the methods of investigation including symptoms and physical signs, the ætiological types of heart disease, structural lesions, and lastly, disorders of function. Part I. includes an excellent account of cardiovascular radiology, an aspect of diagnosis which has hitherto been scantily treated in most English text-books. In other parts of this section the author is apt to over-classify. The statement that such and such a condition may be due to 1, 2, 3, or 4 is a joy to students, but is too watertight for the more advanced reader. In the chapter dealing with sphygmomanometry (p. 127) the author refers to the disappearance of the Korotkow sounds as the diastolic end-point. With this neither physiologists nor clinicians will agree.

Part II. opens with some extremely interesting graphs comparing deaths from heart disease in the United States with those from cancer and tuberculosis, and the age-incidence in fatal cases. But influenza and focal infections, which we regard as important causes of cardiac invalidism, are allotted only half a page each, while gout is dismissed in two lines. Sense of proportion is similarly lacking in the reference to Raynaud's disease and chilblain (Part IV.), and to angina pectoris, to the consideration of which the author devotes only 20 pages. Part III. deals with structural lesions. This inevitably leads to difficulties. Why for example refer at all to "the course, prognosis, and treatment of cardiac enlargement" (p. 468) which obviously varies with the cause of the lesion? And why consider under the heading of aortic valve disease two such entirely dissimilar conditions as syphilitic aortitis and rheumatic endocarditis, or why group together syphilis and atheroma of the aorta? Maybe Dr. White has adhered to an older classification, feeling that in recent years the pendulum has swung too far and morbid anatomy is being neglected at the expense of disorders of function. With this attitude most cardiologists will heartily agree, but the remedy does not lie in merely reverting to the faults of the older classification.

In his general outlook in cardiology Dr. White favours the middle course, as may be seen from his frequent use of the phrase "the truth probably lies between these two extremes," but from time to time he is lured back to the camp of the anatomical diehards. This may be the reason why in enumerating the causes of congestive heart failure (p. 565) he gives first place to valvular defects and includes auricular fibrillation as one of the less common causes of the condition. In England it would be no easy matter to collect a hundred cases of congestive heart failure with normal rhythm. The section dealing with the treatment of congestive heart failure, and especially digitalis therapy, is excellent and full of common sense though exception might be taken to the statement (p. 567) that cardiac dyspnœa is due primarily to oxygen lack.

The book is well got up. The illustrations, many of which are taken from the works of Sir Thomas Lewis, are clear and well produced. An attractive feature is the detailed quotations from the writings of pioneers in cardiology. In his preface the author states that the bibliographic index is intended to be as brief as is consistent with its usefulness. Nevertheless it occupies nearly 200 pages, and gives some indication of the amount of work the author must have put into his book. British cardiologists will find in Dr. White's book a good systematic account of heart disease based on views accepted in great American schools.

Recent Advances in Radiology.

By PETER KERLEY, M.B., B.Ch. (N.U.I.). D.M.R.E. (Camb.), Assistant Radiologist, Westminster Hospital; Radiologist, the Royal Hospital for Diseases of the Chest. London: J. and A. Churchill. 1931. Pp. 324. 12*s.* 6*d.*

THIS volume of the Recent Advances series is written in a clear and convincing style and Dr. Kerley deserves congratulation for having steered his way so skilfully through many of those stretches of radiology that are still uncharted. Sometimes, however, he errs on the side of a dogmatism that is not justified. His insistence on the basic pathology is commendable in a book which is, as it should be, clinical in character.

The general outline and construction of the work are satisfactory, and it is well indexed. On the whole it may be taken as a sound guide, though in certain details the teaching would not be generally accepted. Many hypotheses are set down as facts, as, for example, the statement that "the arch of the aorta is always dilated if aneurism is present in another part of it," or that "we now know Perthes' disease, Kienböck's disease, Köhler's disease and Schlatter's disease to be manifestations of the same disease." The author's gift for clear exposition has led him to make pictures appear more definite and sharply defined than the facts justify, especially in connexion with differential diagnosis. The novice reading this book would see little difficulty in making a definite diagnosis in cases where experience would advise great caution, with efforts to obtain confirmation from every possible source before an opinion is expressed.

Discounting this tendency, which is manifest throughout the book, the volume provides a good résumé of present-day knowledge, especially as regards the German point of view. The names of German workers are freely given to various signs and methods. For instance, the absence of evidence of a gastric peristaltic wave as it passes over an affected area of diseased wall is here called Fraenkel's sign, the reference given being 1927. This phenomenon was noted many years ago in some of the earliest papers on the subject, and there seems little need to associate it with any observer's name. The short chapter on radiotherapy sacrifices accuracy to brevity, and would have been better omitted. The book is well and clearly written and is likely to achieve success. It will be of great value to radiologists, particularly those of experience who can discount the author's enthusiasm and appreciate the vast amount of work that has been embodied in this book.

The illustrative radiograms and line drawings are very clear. Many of the former are touched up to emphasise the points, and although the immediate purpose is served, the novice may carry away a false impression of the appearances he is likely to discover in his own films in similar conditions.

Piersol's Human Anatomy.

Ninth edition. Under supervision of G. CARL HUBER, M.D., Sc.D., Professor of Anatomy and Dean of Graduate School, University of Michigan. London: J. B. Lippincott Company. Pp. 2104. 45*s.*

WE welcome this new edition of a well-known book, which has long passed beyond the region of general criticism. In this issue the new matter has to do mainly with histological questions, such as the origin of blood-cells and like matters, and the B.N.A. has been introduced throughout. Care has been taken to preserve the pagination of the last edition, so that guides and references can remain unchanged. Several new illustrations have been introduced, and the work in general has been brought up to date.

Rest and Pain.

By JOHN HILTON, F.R.S. Edited by W. H. A. JACOBSON. London: G. Bell and Sons. 1931. Pp. 514. 5*s.*

Hilton's famous lectures on the influence of mechanical and physiological rest in the treatment of surgical diseases were published some 70 years ago, after their delivery before the Royal College of Surgeons of England. In these the insistence on the diagnostic value of pain is associated with elaborate knowledge of surgical anatomy, and the popularity which the work obtained is not surprising. During Hilton's life the book was several times revised, but after his death his editor left the text untouched, and between 1880 and to-day 14 editions have been published. Though modern knowledge has made much of the book out of date, its general messages and its philosophy remain just. It is one of the works that promise to earn and keep the over-used epithet of "classic."

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 5, 1931.

THE COMMON COLD.

The medical profession is much abused because it cannot cope with the common cold. Here, people say, is a world-wide disease which is always with us and is responsible for an enormous amount of discomfort and loss of human efficiency; yet nothing is known about its causation, and its treatment is empirical and unsatisfactory. To anyone acquainted with the facts such a criticism is of course manifestly unjust. The problem of ætiology is far from being a simple one; the very fact that it has remained unsolved so long is proof enough of that. None of the ordinary laboratory animals is suited for its investigation and the disease is so widespread in man as to make him of little value as an experimental animal unless he is subjected to most rigorous quarantine and irksome isolation.

For some time now the idea has been current among bacteriologists that the primary cause of the common cold is not one of the ordinary bacteria, but a member of the group of filter-passing viruses. Support to this view was lent by the findings of W. Kruse (1914), G. B. Foster (1916), and H. Dold (1917); but doubts have now been settled beyond all dispute by the masterly investigation which Prof. A. R. Dochez and his colleagues describe elsewhere in this issue. Their work soon led them to the conclusion that the visible bacteria present in the nasopharyngeal discharge were only of secondary importance, so they turned their attention to the filter-passing viruses. And since observation had shown that the chimpanzee was subject to a respiratory infection resembling in every way the human cold, they used this animal for their experimental work. The results of these experiments on apes left no doubt that the cold virus was a filter-passer. Typical colds were produced in chimpanzees by means of the filtered nasopharyngeal washings from human cases, passages in series from ape to ape were realised, and infection by contact was shown to take place. Needless to say the most stringent precautions were taken to exclude infection from outside sources. Dochez and his colleagues then proceeded to carry out the same experiments with human volunteers. Here again the greatest care was taken to ensure that their subjects were not infected before being taken on experiment and that all outside sources of infection were excluded. The human experiments were just as conclusive as those made with the chimpanzee. But this is not all. Using a culture medium consisting of a special buffered broth containing chick embryo tissue and brought to a suitable reduction potential by means of cystein hydrochloride, these workers have been able to cultivate the virus of the common cold. And with the fifteenth subculture, representing a dilution of 1 in 1,000,000,000,000,000, they have produced typical colds in two out of three human volunteers.

Not less interesting are the speculations of Dochez and his collaborators on the part played by this virus in respiratory infections in general. Their experimental work has shown them that this virus renders the respiratory tract more susceptible to the implantation of pathogenic organisms, as well as enhancing the activity of any potential pathogens which may be present there. Observations in America have shown that the common cold has three peaks of incidence, one in September and October, another in January and February, and a third in April and May. Further, the cases occurring in winter and spring are usually more severe than those arising in the autumn. Coincident with this increased virulence of colds as the winter lengthens into spring there is an increasingly wide distribution of such organisms as the pneumococcus, the influenza bacillus, and *Streptococcus hæmolyticus* in the nasopharynx of healthy individuals. Thus as the winter advances the opportunity enlarges for these potential pathogenic organisms to cause infection, with the result that their distribution becomes more widespread and their virulence is probably enhanced. It is at this period of the year that pneumonias and bronchial infections are most common, and it may well be that Dochez's virus is in part responsible for this. Be this as it may, the principal thing for the moment is that the ætiology of the common cold has at last been cleared up. Complete confirmation of these findings is forthcoming from an investigation carried out by P. H. Long and a team of collaborators[1] on human volunteers at the Johns Hopkins University and an important field is opened up for further work. All who have followed these researches of Dochez and his associates must have been struck not only by their thoroughness, but also by their undeviating march towards success. It is a brilliant piece of work.

THE BASEMENT CHILD.

From the Bishop of Southwark we have in a small volume[2] some penetrating observations upon the social conditions of one district of his industrial diocese. He records the circumstances of living which are compulsory upon the inhabitants of the southern shore of the Thames from Battersea to Woolwich, an area that is densely inhabited by a wage-earning class—where, that is, employment is obtaining a return in wages. Dr. Garbett gives a vivid picture, based upon knowledge and checked by experience, of an urban area, where men, women, and children are condemned to make such homes as they can amid the evils of overcrowding—an area where the safeguards of sanitary supervision and the benefits of social service, both well displayed, cannot keep the menaces of ill-nutrition at bay. And the reason is the abominable housing, where basements are always damp and living rooms often so overshadowed by high walls that direct light cannot penetrate them.

[2] In the Heart of South London. By the Right Rev. Cyril Forster Garbett, Bishop of Southwark. London: Longmans Green and Co. 1931. Pp 152. 3s. 6d.

The text of the book was expounded by his lordship recently in the Upper House, when in an eloquent speech[3] he drew attention to the large number of persons now living in underground buildings, not only in South London, or London generally, but in all our big cities. He inquired if the local authorities were playing their part in the construction of new houses to meet the evils of overcrowding, and brought forward a motion for the institution of a central housing council, which, he considered, would stimulate the erection of suitable habitations for the working classes. This motion he withdrew later, on an explanation from Lord SNELL, speaking for the Government, that the powers possessed by the local authorities were already adequate, and the provisions of the Slum Clearance Act of last year were quoted in support of his words. And although Lord SNELL deprecated concentration upon a particular aspect of the evils which had to be dealt with, the Bishop of SOUTHWARK's indictment of basement dwellings made a valuable impression upon the House. And now Dr. GARBETT's words receive powerful endorsement in the report for 1930 of the school medical officer of the London County Council, which appeared this week, for, in a section of his general annual report,[4] Dr. KAY MENZIES includes the results of a special inquiry made by Dr. A. BANKS RAFFLE into the condition of children living in basements, the information being compiled by the inspectors of the Council, and derived from elaborate inquiry among families occupying basements in eight metropolitan boroughs, widely separated in geography, and differing in rateable values.

The boroughs selected were Kensington, Paddington, Westminster, Islington, Finsbury, Poplar, Stepney, and Southwark. The children were examined in their schools, and the findings were checked by double control, each basement child being compared with two non-basement children of the same sex and age, and, as far as possible, in similar social circumstances. In this way 254 basement children were examined and 508 controls, and the examiner was throughout in ignorance which of the little subjects were basement dwellers. The inspection cards revealed that the incidence of pneumonia and bronchitis was not markedly different in the two classes, but there was a definitely higher incidence of diphtheria among the basement children and a greater tendency to rheumatism. The physical examinations were directed especially to debility, defective sight, rheumatism, and rickets. At most ages, and particularly among the older children, the basement children compared unfavourably with the controls in weight and measurement; they were as clean and no more anæmic, but they were not as well-nourished. While defective vision was present in similar proportion—about 24 per cent.—symptoms of rheumatism were nearly three times as frequent among the basement children, and throat and nose affections were found in 7·4 per cent. of the basement children and in only 3·3 per cent. of the controls. Rather unexpectedly rickets was evenly distributed, at just above 7 per cent., between the two classes. At first sight the contrasts revealed do not seem to justify the universal indictment of the basement as a home for children, but Dr. RAFFLE points out wisely that the figures do not tell the whole story. He supports the Bishop of SOUTHWARK's words by saying that in some areas, giving Southwark as the example, it was possible to pick out, on sight, some of the basement children from their controls, while inquiry into educational standards showed that children living in basements do not, as a class, progress at school satisfactorily—the head teachers returning as definitely backward 24·8 per cent. of the controls and 43·6 of the basement children, who; moreover, were double as irregular in attendance. This inquiry may not reveal the lurid conditions expected in some quarters, but it shows enough to give cause for thought to the public authorities concerned. It is the ambition of the financier to get in on the ground floor, but it should not be that of the tenement dweller, whatever the pecuniary inducement.

◆

PINK DISEASE.

THE disorder of childhood to which this name among many others has been ascribed has definite and striking clinical characteristics,[1] but an ætiology and pathology which have not yet been clearly established. For many years it has both fascinated and perplexed pædiatricians, and lately the interest has not been limited to medical circles. The development of our knowledge of the disease, its discovery by independent observers in different countries, and the various titles it has received, furnish material for an interesting study. It is difficult to say whether or not it is a new disease, but the fully developed clinical picture is so characteristic that it seems impossible that it should have passed unrecognised for long, and in this country it is generally conceded that it is a "symptom complex" which was not met with before the late war. Certainly there is no published reference to it before February, 1914, when H. Swift, of Adelaide, reported to the tenth Australasian Medical Congress at Auckland, 14 cases of what he thought was a new disease, and called "erythrœdema." Although this paper constitutes the first printed account, the condition was noticed in Australia many years before, for A. J. Wood,[2] in 1921, reporting a series of 91 cases, remarked that he had seen examples of the disease at Melbourne for 30 years previously, and that even before that time W. Snowball of the same city had recognised it and spoken of it as "raw beef hands and feet." C. B. Clubbe had also observed the disease in Sydney for several years before this date, and is responsible for calling it "the pink disease," a name which possesses advantages over many of its synonyms in that it accurately describes the chief symptom, is not misleading, and does not commit the user to any particular view of its pathology. The condition also seems to have been recognised in Germany and France some years before it was recorded, for in a paper published by P. Selter[3] in 1926–27 he states that in 1903 he reported eight cases under the title of "trophodermatoneurose" or "vegetative neurosis" to a medical society at Cassel, in Germany; and P. Haushalter,[4] of France, writing in 1925 on a "neurovegetative syndrome in infants," remarked that he had been familiar with the syndrome since 1911.

---

[1] THE LANCET, 1921, i., 871.

[2] Med. Jour. Austral., 1921, i., 145, see THE LANCET, loc. cit.

In the United States of America the disease seems first to have made its appearance about 1915, and in Canada in 1918, although its identity with the pink disease of Australian writers was not recognised until some years later. In 1917 A. H. Byfield, in a paper read by title before the American Medical Association, described the earliest cases as "trophoneuroses probably due to an infection," and again in 1920 as "a polyneuritic syndrome resembling pellagra-acrodynia (?) seen in very young children."[5] A little earlier in the latter year J. B. Bilderback had recorded some instances of an unknown disease which he had met with in his practice; later W. Weston[6] came to the conclusion that these were examples of a disease which assumed epidemic proportions in Paris in 1828–29, and to which the name of acrodynia was given by Chardin. In 1923 it was quite clearly pointed out by J. Zahorsky that all these American cases were identical with pink disease. Although Weston and many other American authorities still regard pink disease as a juvenile form of acrodynia, it is highly improbable that the two diseases are identical, one reason being that acrodynia was an epidemic disorder attacking adults, whereas pink disease is a sporadic disease of infancy and early childhood; further, Petren has produced good evidence to show that acrodynia was due to the drinking of wine contaminated with arsenic. In England the first case of pink disease was described in 1921 by Parkes Weber, who demonstrated it before the Dermatological Section of the Royal Society of Medicine as "a condition somewhat resembling lupus pernio in a child"; in 1922 H. Thursfield and D. H. Paterson[7] published a report of a case under the heading of "dermatopolyneuritis"; and in 1923 L. G. Parsons[8] reported six cases, two of them observed in 1920. E. Feer,[9] of Zürich, was the first continental writer on this disease, and in 1923 he redescribed the condition as a "neurosis of the vegetative nervous system," pointing out that many of the characteristic symptoms were referable to a disturbance of the sympathetic nervous system—e.g., extreme irritability, sweating, cold and clammy extremities, tachycardia, raised blood pressure, salivation, hypotonia, photophobia. This communication created such an impression that on the continent the disorder is usually referred to as "Feer's disease."

An annotation in our issue of May 2nd summarised some of the latest necropsy findings, and W. G. Wyllie and R. O. Stern[10] have just published an important paper recording the pathological findings of seven further cases. Degenerative changes were found in the peripheral nerves of four of them; chromatolysis of the central type, more apparent in the lumbo-sacral cord than elsewhere, was present in the anterior horn cells in five; and in all cases the spinal cord showed that diffuse infiltration with small cells which was first described by J. G. Greenfield and Paterson. These results, they state, confirm those already recorded and afford further evidence that lesions in the nervous system are to be found in a large proportion of cases. Taking all the published morbid findings into consideration it must be admitted that as yet no single lesion has been established as a constant characteristic of the disease, and it is a point of some significance that the clinical symptoms have always been considerably in excess of the pathological findings. It is therefore not surprising that the ætiology of pink disease has given rise to much discussion. Three theories of its causation have been propounded: First that it is a deficiency disorder; secondly that it is the result of an infection; and thirdly that it is a dysfunction of the vegetative nervous system. The resemblance to pellagra, which was commented upon by the earlier American writers, is a point in favour of the deficiency theory, and some transatlantic authorities still believe that the two diseases are related. There are, however, essential differences between them, perhaps the most obvious being the absence in pink disease of the seasonal variations of the rash which are so characteristic a feature of pellagra. Again, a deficiency in any of the known vitamins has never been demonstrated in the diets of sufferers from pink disease. On the other hand, Marshall Findlay and R. O. Stern[11] found that young rats developed a clinical condition which resembled pink disease, and pathological changes in the peripheral nerves, and a cellular infiltration of the cord similar to that described in autopsies on pink diseases, when they were fed on a diet which contained all the known vitamins but in which the sole source of protein was egg white. Moreover, this condition was cured by the addition of dried yeast or raw liver to the diet, which suggested that it was due to a deficiency in some dietetic factor but not one of the known vitamins. Applying these findings to children suffering from pink disease, Wyllie and Stern report the recovery of five patients fed on a liver diet, and they consider that there is a dietetic factor contained in liver which has a definite curative value.

The not infrequent occurrence of prodromal catarrhal symptoms in connexion with the nose and throat; the increased incidence shortly after the last great pandemic of influenza; and the appearance of acrodynia in 1828, exactly one year after the first influenza pandemic of the nineteenth century, have all been stressed as points in favour of the infective theory. M. Péhu and A. Mestrallet believe that the condition is the result of a specific infection of the nervous system, closely analogous to encephalitis, and both H. Janet and R. J. Turquety maintain that it is due to a neurotrophic virus which gains access to the nervous system through the naso-pharynx. The pathological evidence in favour of the infective theory is, however, but slight. Finally Feer's suggestion that the condition is a functional disorder of the vegetative nervous system rests on the clinical evidence of such a disturbance, and the fact that in one fatal case he could not find any alteration in the sympathetic system after a very careful examination. However true it may be that such a disorder of function is the cause of the symptoms, this theory does not provide any explanation of the functional disturbance itself. What evidence there is as to the cause of pink disease appears to favour a dietetic deficiency as *an* ætiological factor, although possibly not *the* factor. Indeed it may well be that, as first suggested by Byfield, the disease, or the dysfunction of the vegetative nervous system which produces it, is due to a combination of the first two causes—in other words, that a dietetic deficiency may produce a state which favours an infection.

ANNOTATIONS

FOOD-POISONING IN CALIFORNIA.

At one time California had an unenviable notoriety for outbreaks of botulism, but vigorous action has reduced these to small proportions. The three examples of food-poisoning now reported from this State by Prof. A. J. Geiger and co-workers[1] were due to salmonella organisms. In the first, at Sacramento in January, 35 persons were visited with diarrhœa, vomiting, and the usual acute symptoms. The incubation period was very short, being two and a half to four hours, but there were no deaths. The sufferers belonged to a party of 60 who attended a late evening banquet. While a considerable number of foods were eaten, inquiry showed fairly definitely that the main meat course of chicken and chopped-up veal, with cream sauce, was at fault. From this *Bacillus enteritidis* was isolated, but with great difficulty, partly, it seems, because the bacilli were very scanty and partly because the mixture was heavily contaminated. The premises were rat-infested, and the authors consider that rats were the probable source of the infection. The mixture was given ample time to be infected, for the chickens were cooked and boned on Jan. 18th, left about overnight, and mixed with the veal on the 19th, and the mixture with cream sauce was warmed up on the 20th to be served at the late supper. Another outbreak was at a hospital, and 200 people were afflicted with somewhat similar symptoms to those of the Sacramento outbreak. The incubation period was also short, two to four hours, and again there were no deaths. While the food involved seems definitely to have been rice pudding covered with a fruit sauce—since this was the only food eaten in common—the evidence does not clearly show the course of infection. A *B. aertrycke* strain was isolated from the rice pudding, and was not found in the original rice. Only one stool of a sufferer was examined, and that revealed nothing, while no agglutination blood tests were carried out. There is no actual proof therefore that the patients suffered from a living infection with this organism. The pudding was heated in a steam cooker for about an hour, and then kept for six to eight hours before being served. Possibly infection took place subsequently, but apart from an unconfirmed suspicion that a commercial rat-killer had been employed, no source of infection was found. No information is given about the source of the milk used.

The third outbreak, which was in March, was also in a hospital, and caused the illness of 52 persons. Here, too, there was a short incubation period (three to four hours), the symptoms being nausea, vomiting, diarrhœa, and great prostration. The peccant food was an egg soufflé shrimp mixture, served with tinned peas; it was harmless when first eaten, but after remaining overnight in the kitchen it became definitely poisonous on being warmed. *B. paratyphosus* A was isolated from a stool from the assistant cook, and the outbreak is ascribed to this organism; but there is insufficient warrant for this. Three excreta samples were negative, and in the single fatal case the internal organs disclosed no food-poisoning bacilli such as are to be expected almost invariably when death is due to a living salmonella strain. No blood agglutination tests are recorded, and none of the food mixture eaten was available for bacteriological examination.

Apart, however, from obscurities about the exact bacterial strain responsible, and whether the illnesses were due to living bacilli or to their toxins only, the three outbreaks illustrate the fact that food-poisoning is usually due to manipulation of food, which gives opportunities of infection, and that the greatest danger comes from meat or milk foods which are heated and then left about to get cool. The greatest attention must be paid to the storage of foods which have been heated and are allowed to cool slowly, and this especially applies to those which are good culture media for the food-poisoning bacilli. Such attention, together with scrupulous cleanliness, will prevent a considerable proportion of outbreaks; and perhaps the lesson is being slowly learnt. In Great Britain food-poisoning has been relatively commoner than in the United States, but of late it has seemed to be diminishing.

BLOOD TRANSFUSION IN STREPTOCOCCAL SEPTICÆMIA.

The treatment of streptococcal septicæmia by immuno-transfusion, as advocated by Almroth Wright in 1918, is the subject of a study by Prof. P. Abrami and Dr. A. Tzanck in *Paris Médical* for August 1st. After discarding some 29 cases, because sufficient data were not available, they confine their observations to

---

[1] Public Health Reports, Washington, July 3rd, 1931, No. 27, xlvi., 1565–72.

43 cases of streptococcal septicæmia in which a hæmolytic streptococcus was either actually found in the blood (22 cases) or the case was recognised as such on circumstantial evidence. Those in which it could not be found in the blood were not as a class any more benign than the blood-positive cases, among which there were 12 recoveries. Among the blood-negative cases there were nine recoveries. The donors were sought as far as possible among women who had recovered from puerperal fever, and had been inoculated according to the technique described by Jaubert in 1928. Further, whenever it was possible, the donor was reinoculated with autogenous vaccines, made from the patients themselves within six hours of the transfusion. The cases recorded in some detail emphasise the point, made by the authors early in their paper, that the measures adopted in each case were as varied as were the processes which led to recovery in such a goodly proportion of their cases. It follows that their study is not of the kind that lends itself to summary review.

INTRACRANIAL TUMOURS.

THE last 20 years have seen considerable advances in our knowledge of intracranial tumours from their clinical, pathological, and therapeutic aspects. The time is therefore ripe for a critical review of this subject and Dr. F. M. R. Walshe's paper [1] is a valuable survey of this wide and ever-widening field of medicine. It was impossible within the limits imposed to deal with the whole of our present knowledge of intracranial tumours, and Dr. Walshe has necessarily confined himself to what may be termed the growing points of the subject. The clinical and therapeutic importance of the pathology of tumours of the brain was hardly recognised at all until comparatively recently. Chiefly owing to the researches of Cushing and his pupils it has been learned that the different types of tumours, even the different types of glioma, often exhibit a characteristic age-incidence and rate of growth and a predilection for certain situations in the brain. Hence it is becoming possible for the clinician with increasing frequency to diagnose not only the presence and situation of an intracranial tumour, but also its precise pathological nature, which proves of importance in forming an accurate estimate of its prospect of removal, of the peculiar difficulties likely to be encountered in the task, and of its probable malignancy. The importance of pathology is reflected in the fact that Dr. Walshe devotes more than a third of his paper to the classification of intracranial tumours. He gives an admirable account of the development of the modern conception of the gliomas as tumours corresponding in structure to different stages of development of embryonic neural tissue, and though he does not commit himself to the finality of any existing classification, he fully recognises the importance of current theories.

Dr. Walshe analyses the pathological physiology of raised intracranial pressure and rightly lays stress upon the importance of generalised epileptiform fits as an initial symptom of tumour. Except among neurologists it is inadequately recognised that "generalised epileptiform fits making their first appearance in an otherwise healthy subject in the fourth or fifth decades of life should at once raise a suspicion of intracranial tumour." In considering some localising symptom-complexes he devotes special attention to tumours in the neighbourhood of the optic chiasma, whose early recognition is of great importance for the preservation of vision. He is refreshingly critical of current loose conceptions of pathological sleep and "the sleep centre."

Any impartial worker cannot fail to be impressed with the revolution in the diagnosis of intracranial tumours which has been brought about by radiography. Not many years ago it was held to be useless to radiograph the skull in cases of suspected tumour because no abnormality was likely to be found. Since then we have learned that even if the tumour itself is invisible valuable clues as to its presence and situation are often provided by alterations in the bones of the skull, and the intraventricular or intrathecal injection of air has in many cases established the localisation of a growth when clinical methods have failed to do so. Dr. Walshe puts the case for the use of these accessory methods of investigation very fairly, rightly emphasising that they are supplementary to clinical methods. Advances in the surgery of the nervous system do not come within the scope of his review and little is as yet known concerning the value of therapeutic irradiation in the treatment of tumours of the nervous system. The important principle which underlies any method of treatment of intracranial tumour is that it must take full account of the pathological nature of the growth.

THE NEW CONVENTION ON NARCOTIC DRUGS.

THE conference on the limitation of the manufacture of narcotic drugs, which sat at Geneva from May 27th to July 13th, under the presidency of Mr. de Brouckère, of Belgium, concluded a new convention which is intended to "supplement" the Opium Conventions of 1912 and 1925 by seeking to render more effective the international control of the traffic in drugs of addiction. It will be remembered that the Geneva Convention of 1925, while reciting that "results of great value" had been produced by the original Hague Convention of 1912, nevertheless deplored that "the contraband trade in, and abuse of, the substances to which the convention applied still continue on a great scale," and accordingly sought "to complete and strengthen the provisions" of the earlier treaty. The draft of the new convention has now been published, and it may be well to consider in what respects it indicates an advance upon the international obligations already entered into by the high contracting parties.

The new convention, unlike those of 1912 and 1925, has little concern with raw opium or prepared opium, and deals mainly with morphine and cocaine and their derivatives. Article 2 defines "the drugs" to which the provisions are applicable, and the handiwork of the experts who advised the conference is evident in adding to morphine, diacetylmorphine, and cocaine and their salts the following: dihydrohydroxycodeinone, dihydrocodeinone, dihydromorphinone, acetyldimethylodihydrothebaine, dihydromorphine, their esters and salts. In a subgroup appear ecgonine, thebaine and their salts, benzylmorphine, and the other esters of morphine and their salts; while in a separate group are placed methylmorphine (codeine), ethylmorphine, and their salts.

Each contracting party is to furnish annually to the permanent central board estimates of the drugs required, distinguishing the amounts for use for medical and scientific purposes (including export), for conversion, for reserve stocks, and for Government requirements. The seven chapters and 34 articles of the new convention amount, in fact, to an elaboration of the provision contained in Article 9 of The Hague Convention, which reappeared as Article 5 of the Geneva Convention of 1925, which was as follows :—

---

[1] Quart. Jour. Med., 1931, xxiv., 587.

> "The contracting Powers shall enact pharmacy laws or regulations to limit exclusively to medical and legitimate purposes the manufacture, sale, and use of morphine, cocaine, and their respective salts, unless laws or regulations on the subject are already in existence. They shall coöperate with one another to prevent the use of these drugs for any other purposes."

The foregoing restriction was also to apply to medicinal opium, to heroin, to all preparations containing more than 0·2 per cent. of morphine or more than 0·1 per cent. of cocaine, and to all new derivatives thereof and to other alkaloids of opium which may be shown to be liable to similar abuse.

The estimates furnished by the contracting parties are to be examined by an advisory body of four persons appointed respectively by the League's advisory opium committee, the central board, the health committee of the League, and the Office International d'Hygiène Publique. The estimates, with any explanations that may be vouchsafed, and any observations of the supervisory body, will be supplied to all the Powers concerned. Manufacture of any of the drugs in excess of the estimates is not to be permitted, due regard being had to imports and exports. Export of heroin, except to countries which do not manufacture it, and then only on import certificate and consignment to government, is forbidden. New drugs derived from opium or coca are not to be manufactured unless the government concerned is satisfied of their medical value; and if the health committee finds they are drugs of addiction they shall be subject to the provisions of this convention. Preparations containing less than 0·2 per cent. of morphine and less than 0·1 per cent. of cocaine, and preparations of codeine and ethylmorphine (with some reservations) are to be brought under control. Every year the permanent central board is to report for each country the estimates for each drug, together with the amounts consumed, manufactured, converted, imported, and exported. Explanations vouchsafed by any contracting party of failure to carry out his obligations will also be published, but not "in such a manner as to facilitate the operations of speculators or injure the legitimate commerce of any high contracting party." Each party is to create a "special administration" for applying the provisions of the convention, supervising the trade in drugs and "organising the campaign against drug addiction." Strict supervision over "raw materials" is to be required and drugs seized in illicit traffic are to be destroyed, converted into non-narcotic substances, or appropriated to medical or scientific use under government control. Particulars of each case of illicit traffic are to be communicated, through the secretary of the League of Nations, to the other parties to the convention.

The chairman of the conference claims that it has "succeeded," but it has to be remembered that it will not come into force until "90 days after the secretary-general of the League of Nations has received the ratifications or accessions of 25 members of the League of Nations or non-member States, including any four of the following: France, Germany, United Kingdom of Great Britain and Northern Ireland, Japan, Netherlands, Switzerland, Turkey, and United States of America." In the final act attached to the convention the governments are invited to consider the desirability of setting up State monopolies over the manufacture and trade in narcotic drugs, but the German delegation dissented from this proposal. A suggestion is also made as to the possibility of replacing heroin by a drug of less dangerous character. Finally an approximate estimate of the annual world requirements is tabulated as follows: morphine, 9 tons; heroin, 2 tons; cocaine, 5½ tons.

GANGRENOUS APPENDICITIS.

IT is gradually being recognised that there are two types of "acute appendicitis," one which without early operation rapidly goes on to perforation and general peritonitis, and the other which often subsides without surgical intervention, although it may be followed by recurrent attacks. This fact has led to the practice by some surgeons of the "delayed treatment" of acute appendicitis. D. P. D. Wilkie[1] has adduced evidence to show that the former type is primarily not an inflammation but an acute obstruction, and that all cases of gangrenous appendicitis are the sequel of an obstruction of the lumen, usually by a fæcolith. He states that while acute obstruction of the appendix is, without surgical treatment, a most deadly disease, acute inflammation of that organ is comparatively harmless. LaRoque[2] now puts forward a claim for the value of a sign, first noted by R. Brittain in 1928, in the diagnosis of gangrenous appendicitis. This sign is elicited by pressure on the right lower quadrant of the abdomen, especially at McBurney's point, when the right testicle is immediately drawn upwards. As a rule the testicle remains retracted until the pressure is withdrawn, it then returns to its original position. Occasionally, however, the testicle may drop back although pressure is maintained, only to retract again momentarily as the pressure is removed. Since the sign has been present in nearly 500 cases of gangrenous appendicitis, and has not been found in a series of more than 300 cases of other acute abdominal conditions, LaRoque regards it as pathognomonic of gangrenous appendicitis and an indication for immediate operation.

CARE OF THE INSANE IN IRELAND.

THE irony of Dean Swift's end has often been commented on, but it is seldom recognised that when "he gave the little wealth he had to build a house for fools or mad" he was endowing the first public hospital in Ireland to be wholly devoted to the care of the insane. In an interesting paper,[3] written for annual meeting of the Royal Medico-Psychological Society in Dublin, Dr. Kirkpatrick has described the scanty, and often barbarous, provision that existed prior to 1735, when Swift resolved to settle "his whole fortune to erect and endow an hospital for the support of idiots and lunatics." The matter went forward slowly. At first the mayor and aldermen of Dublin were named as trustees, but presently "upon the City's favouring Fanatics" the will was altered, and it was not until May, 1740, that it was signed in its final form. On August 16th, 1742, a writ *de lunatico inquirendo* was issued, and returned the next day, finding the Dean of St. Patrick's a person of unsound mind; three years later he died. In 1757 his intention was realised and the hospital declared open. For the next 50 years St. Patrick's continued to be the only hospital of its kind in Ireland, though the Houses of Industry in Cork, Dublin, Limerick, and Waterford sheltered many lunatics, along with prostitutes, incorrigible offenders, vagabonds, and others. In 1810 the Bloomfield Retreat was opened by the Quakers, following the example of their kind in York, and in the same year the Government made the necessary grant for building the Richmond Asylum; in both of these institutions humane and enlightened methods of treatment were employed from the first. During the next half century much was done, largely by Act of Parliament, so that in 1851 there were 11 district asylums, besides a number of private mental hospitals, so well managed as to earn the praise of Conolly of Hanwell. By 1900 the number of district asylums had been doubled and there was steady advance in many directions.

[2] LaRoque, G. P.: Amer. Jour. Med. Sci., August, 1931, p. 191.

[3] A Note on the History of the Care of the Insane in Ireland up to the End of the Nineteenth Century. By T. Percy C. Kirkpatrick, M.D., Litt. D. Dublin: The University Press. 1931.

In Ireland, as elsewhere, the history of the care of the insane is for the most part a painful story of insensibility and cruelty, now happily ended; but in this case it is illuminated at its beginning by the remarkable regulations of the ancient Brehon laws, codified about the time of St. Patrick, in which appears an enlightened concern about the duties of the healthy community towards those "on whom the maddening wisp had been thrown," to use the old Irish phrase. The sagacious rules there laid down to prevent the insane from having offspring are nowadays of particular interest.

MENINGITIS DUE TO THE SPIROCHÆTE OF JAUNDICE.

LATELY several cases of meningitis in Paris have been traced to infection with the spirochæte of Weil's disease (*Leptospira icterohæmorrhagiæ*). In some of them there was no jaundice, and the diagnosis was suggested by the occupation of the patient, and proved by the high titre of the antibody reaction given by the patient's blood. One which is typical of the condition is described by Harvier and Wilm.[1] It was that of an exhibition diver at a restaurant, who became ill in December with evident signs of meningitis. Lumbar puncture gave an opalescent fluid with 350 cells per c.mm., 95 per cent. of which were polymorphonuclear leucocytes; it contained no visible bacteria, and cultures, on ordinary media, remained sterile. The patient recovered after repeated lumbar punctures in ten days' time, but five days later a second rise of temperature occurred, this time without meningeal symptoms. Schwarz, who has collected seven other non-jaundiced cases, describes the condition as an acute form of meningitis with severe contractures of the legs, but without herpes, petechial rash, or conjunctival congestion. The cerebro-spinal fluid may be opalescent on the sixth to the eighth day of the disease, if the meningeal reaction is severe, in which case the cells are chiefly polymorphonuclear, or it may be clear with a cell count either of mixed type or principally mononuclear. In other cases the meningitis has been ssociated with inflammation of other serous membranes—pleural, peritoneal, and synovial—which has cleared up without leaving any trace. The condition s one which might easily pass undiagnosed unless he possibility of spirochætosis were kept in mind, nd the fact that infection by the spirochæte may roduce symptoms other than jaundice is of importnce from the point of view of public health.

PYREXIAL TREATMENT OF CHOREA.

SOME two years ago a drug called Nirvanol was introduced for the treatment of chorea.[1] Eight to 14 days after administration is begun it produces a reaction in the form of fever, rash, general malaise, and an eosinophilia. Treatment is immediately suspended, and the chorea improves as the reaction subsides. Occasionally, however, the sequels of the reaction are not so happy, as is emphasised by F. Goebel,[2] who has seen purpura hæmorrhagica, nephritis, and a fatal case of dermatitis *exfoliativa* following the exhibition of nirvanol for chorea. He points out that although this drug is effective in treating the disease, it cannot be recommended with confidence, since it may actually cause death, and such a catastrophe can at present be neither foreseen nor prevented. Most observers think that the improvement in the chorea is not directly due to the fever so produced, since similar improvement may follow apyrexial reactions. L. P. Sutton,[3] however, now describes 25 cases of chorea in which rapid and striking amelioration followed pyrexial therapy. In the first case the fever was the result of accidental overdosage with phenobarbital, and the improvement which followed prompted the further investigations. The other 24 cases were treated by intravenous injections of typhoid-paratyphoid vaccine administered daily for as long as six or seven days, the dose being graduated so as to produce a febrile reaction lasting six to seven hours with each injection. Under this régime the average duration of symptoms after the onset of treatment was eight to nine days. The advantages claimed for this method are that it causes fever immediately, is capable of producing it in any patient, and is not complicated by rashes or other disturbances.

ENCEPHALITIS FOLLOWING VACCINATION OR EXANTHEMS: A REQUEST TO PRACTITIONERS.

THE Ministry of Health has issued a statement asking medical practitioners to help in maintaining full investigation of nervous manifestations (meningitis, encephalitis, polio-encephalitis, &c.) developing within four weeks of vaccination. A similar request in 1926 provided material for the consideration of the Rolleston committee. Having issued two reports[4] the committee has now ceased work, but particular study of these rare cases is still required. Furthermore, the Ministry now wants information about cases of acute disease of the nervous system following acute infections, such as measles, German measles, chicken-pox, whooping-cough, or influenza; for the Rolleston committee noted that such conditions bear a close pathological resemblance to post-vaccinal encephalitis and demand continued study and comparison. Communications of the kind requested, if received in time, will permit of local inquiry to ascertain clinical details which may not subsequently be obtainable, and will sometimes enable the department to arrange for expert post-mortem examination and pathological examination of specimens. Practitioners are therefore asked to report without delay every case of disease of the central nervous system with an acute onset within four weeks of vaccination or immediately following an acute infectious illness. The intimation should be sent to the Senior Medical Officer, Med. I., Ministry of Health, Whitehall, London, S.W.1.

[2] Deut. Med. Woch., July 31st, p. 1313.

[3] Jour. Amer. Med. Assoc., August 1st, p. 299.

[4] Report of the Committee on Vaccination, Cmd. 3148. See THE LANCET, 1928, ii., 233. Further Report of the Committee on Vaccination, Cmd. 3738. See THE LANCET, 1931, i., 85, 97.

The statement adds that the Lister Institute has prepared an antivaccinal horse serum, doses of which can be supplied on application to the Ministry. It also calls attention to a reference, in the report of the Committee on Vaccination, to the success which has been obtained in certain cases by the treatment of post-vaccinal encephalitis by intravenous injection of serum derived from persons who have been recently vaccinated.

EARLY CARDIAC FAILURE.

WHEN there is a long history of diminished cardiac reserve, and one finds localised or generalised œdema, evidence of stasis in the liver and lungs, and definite pathological signs in the heart itself, the diagnosis of cardiac failure is simple. But this is an end-result, an acknowledgment of defeat by the patient and by his doctor, and to-day, when the prevention and early diagnosis of disease is rightly emphasised, and when heart failure is still responsible for the deaths of many men and women at the height of their mental abilities, we must focus attention chiefly on the early condition. A recent review by Prof. L. Bogendörfer[1] shows that the greatest importance, as Mackenzie taught, is still to be attached to an accurate history; it is essential at the same time to make a close study of the patient's mentality, for otherwise symptoms due in reality to early cardiac failure may easily be attributed to neurosis. Bogendörfer describes tests for the estimation of cardiac function, but since Nature knows no average, attempts to estimate cardiac reserve by counting the *absolute* increase of the pulse-rate after exercise such as knee-bending are likely to fall to the ground. The same applies to blood pressure and the quality of the pulse; the latter is often used to gauge the power of the heart, but actually it depends not only on the volume per beat of the heart, but also on many arterial factors. Repeated examination of the same patient, however, may be very valuable. Less often emphasised, but well worth attention are minor disturbances of water metabolism. The heart normally works with part only of its available power; with increased needs reserve powers which the healthy heart can easily and rapidly supply are called into play. With ordinary daily wear and tear the reserve power of the heart becomes insufficient, and water tends to be stored in the body by day, only to be excreted at night. Hence the importance, as Quincke pointed out, of nocturnal enuresis as an early symptom. The body, Bogendörfer points out, can retain considerable amounts of fluid without the development of visible œdema, and even 4–7 litres accumulated may give rise to no signs of œdema or transudate into the body cavities. This latent œdema, he says, can only be unmasked by the regular use of the weighing scales and with the estimation of intake and output of fluid. Kauffmann has shown in apparently fully compensated heart disease that raising the end of the bed will result in increased secretion of urine; 5 oz. of tea are given hourly to the patient lying flat in bed and the bladder is emptied hourly; after four hours the foot of the bed is raised and the patient is kept in this position for two hours, urine again being passed hourly. Small amounts of rather more highly coloured, acid urine, with a higher specific gravity, perhaps containing a trace of albumin, are passed in the first period; an increased amount of urine of low specific gravity passed in the second period is a certain sign of latent œdema. Attempts have also been made to estimate cardiac reserve by determining how long a patient at rest can hold his breath after full expiration; he then is exercised by a quick walk and again holds his breath after full expiration. The time taken depends partly on volition, but also to a large extent on the rapidity with which carbon dioxide accumulates in the blood.

SCARLET FEVER IN INDIA.

IT is not so many years ago that enteric fever was supposed to be rare amongst Indians. This belief, owing to blood tests and more frequent post-mortem examinations, is now exploded, and it appears that the impression, widespread until recently, that scarlet fever is almost if not entirely non-existent amongst Indians, must go the same way. It is at any rate seriously challenged[1] by Dr. P. T. Patel, who is in charge of the principal infectious diseases hospitals in Bombay. Few physicians can have practised for many years in India without occasionally coming across a sporadic case having all the classical features of scarlet fever, but such cases are almost always in Europeans, and it is usually impossible to trace their origin. Leonard Rogers remarked (1919) that scarlet fever occurs in India as an imported infection, that there is no evidence that it is an indigenous disease, and that it rarely if ever attacks Indians. This is the view that has hitherto been generally accepted. From time to time, however, cases resembling scarlet fever have been reported in Indians, and in 1920 K. Macleod came to the conclusion that the disease did affect Indians, though showing no disposition to become epidemic among them. Since then isolated cases have been repeatedly observed in Bombay and elsewhere, and Dr. Patel is now definitely of opinion, from his own observation, that scarlet fever is indigenous in India, and he quotes many cases in support of this view. The suggestion is made that climatic conditions have modified the disease, and it is clear that the rash may easily be overlooked on a dark skin.

ARISTIDES AGRAMONTE.

Dr. Agramonte, who has just died of heart disease at New Orleans at the age of 62 years, was the last survivor of the four actors in a brilliant episode in the story of yellow fever. With Walter Reed, James Carroll, and Jesse Lazear, he was sent by the Surgeon-General of the United States Army to Cuba in June, 1900, to investigate the epidemic of yellow fever then raging there. The sequel is well known. Two of the commissioners, along with other volunteers, lived among yellow fever patients in wards from which mosquitos were excluded, and remained free from infection even though surrounded by the excreta and vomit of these patients, proving that transference of the disease takes place normally through the bite of the mosquito alone. Dr. Agramonte was a native of Cuba and left the island at 2 years of age when his father was killed by Spanish troops. He qualified at Columbia College in New York in 1892, and soon after became bacteriologist to the Board of Health. In 1901 he was transferred to the University of Havana, leaving that post to be head of the department of tropical diseases at the new medical school of Louisiana State University. This summer he was elected president of the Pan-American Medical Congress to be held next year in New Orleans.

SPECIAL ARTICLES

STUDIES OF THE MECHANISM OF UPPER RESPIRATORY INFECTION.

By A. R. Dochez, M.D.,
PROFESSOR OF MEDICINE IN THE COLUMBIA UNIVERSITY, NEW YORK;

Katherine C. Mills,

and

Yale Kneeland, Jun., M.D.

(From the Department of Medicine, College of Physicians and Surgeons, Columbia University, and the Presbyterian Hospital, New York.)

For many years investigators have sought to discover the ætiology of the common cold. Many organisms have at different times been assigned a causative rôle, and frequently the evidence in favour of one or another agent has been impressive. In general, however, such organisms have seemed to be of local importance, and not to have had a universal significance. Many of the organisms described are well-recognised pathogens of the upper respiratory tract, and their importance is apparent to all students of upper respiratory disease, but none has an established position as the principal initiating agent of upper respiratory infection. Our own studies of this type of infection have led us to believe that the visible bacteria that can be more or less readily cultivated from the upper respiratory tract during infection are not of primary significance, but must for the most part be assigned the rôle of secondary invaders.

Important evidence has already been accumulated suggesting that the primary agent of the simple type of respiratory infection that goes by the name of the common cold may belong to the order of the ultra-microscopic viruses.[1] The studies which we have carried out offer definite evidence in support of this point of view.

Observation has confirmed the opinion that anthropoid apes, particularly the chimpanzee, are susceptible to acute upper respiratory infections that resemble in every respect the same type of infection in man. Such infections are readily communicable from man to the ape, and from ape to ape. Study of the bacterial flora of the upper respiratory tract in chimpanzees shows it to resemble that of man to a remarkable degree. These animals, therefore, should prove to be excellent animals for study of the experimental transmission of acute upper respiratory infections. Such in fact has proved to be the case.

EXPERIMENTAL INFECTION IN APES.

A colony of young chimpanzees was assembled and placed under observation. To guard against accidental infection the animals were kept in specially organised rooms under rigid quarantine whenever experimental procedures were in progress. When such animals are inoculated intranasally with bacteria-free Seitz filtrates of nasopharyngeal washings from individuals with acute colds, within from 24 to 48 hours the apes begin to manifest signs of upper respiratory infection. These signs are clearly objective, and consist of sneezing, coughing, nasal obstruction, and a mucoid or muco-purulent nasal discharge. These phenomena persist for from five days to two weeks. Such experimental infections are readily communicable by contact to healthy chimpanzees placed in the same cage, and can be passed experimentally from animal to animal by the technique described. Experiments of this nature have been successfully performed over a period of several years and leave no doubt that the infection in question is communicable by means of a filtrable agent.

Perhaps the most significant change, from a bacteriological standpoint, has been the increase of activity on the part of the potential pathogens habitually present in the throat flora of the apes. Coincident with the appearance of symptoms, pneumococcus, *Streptococcus hæmolyticus*, *Bacillus pfeifferi* have developed in greatly increased numbers, and have spread over a wide area of the nasopharyngeal mucous membranes. These organisms become at this time conspicuous even in the nose where they are seldom or never present under normal conditions. We have also observed that during the period of acute infection animals who carry hæmolytic streptococcus may readily communicate this organism to contact animals. Such transference does not easily take place from carrier to contact in the absence of acute respiratory infection in the carrier animal.

EXPERIMENTAL INFECTION IN MAN.

Studies of experimental transmission of colds have also been carried out with human subjects. Human volunteers were carefully isolated and inoculated intranasally with bacteria-free filtrates from individuals suffering from acute colds. After an incubation period of about 24 hours the inoculated subject has manifested the signs of the common cold, and has run a typical course of symptoms lasting from one to two weeks. Such experimental colds in human beings have been passed in series from individual to individual. These human experimental colds differ bacteriologically from the experimental cold in the chimpanzee in that there is no immediate evidence of increased activity on the part of the potential pathogens harboured in the human nasopharynx. The same difference in bacterial activity is manifest between the spontaneous cold in the chimpanzee and the spontaneous cold in human beings.

THE VIRUS IN VITRO.

When we had satisfied ourselves that the common cold is caused by a filtrable virus, our next efforts were directed toward cultivating the causative agent in vitro. The first steps in the successful carrying out of such a procedure must naturally be directed toward an attempt to preserve the virus in an active form outside the animal body.

In order to test survival of the virus after removal from the human body, nasopharyngeal washings were obtained in the manner previously described from individuals within the first 24 hours of a typical attack of common cold. The material was quickly passed through a Seitz filter, and the filtrate was subsequently tested for its capacity to induce the symptoms of the common cold in chimpanzees and in human volunteers. The filtrates with cystein hydrochloride added were preserved anaerobically under vaseline seal both at room and at ice-box temperature. In a few instances the filtrate was concentrated to approximately one-seventh its original volume by vacuum distillation. Of 12 inoculations of filtrates preserved in this manner nine have produced in the inoculated subject typical symptoms of the common cold. The duration of time of preservation of active filtrates has ranged from 4 to 13 days. Tests of survival beyond the thirteenth day have not been made. Positive results have been obtained with filtrates kept at room temperature, and with those kept at ice-box temperature, and with both the unconcentrated filtrate and with that concentrated by vacuum distillation. From these experiments we conclude that the virus of the common cold survives under suitable conditions for at least 13 days after removal from the human body.

In view of the capacity of this virus to survive in what might be considered an adverse environment an effort was next made to cultivate the agent in living tissue medium. Foster[2] has previously reported the cultivation of an organism from patients suffering from the common cold. The method of culture chosen by us has been that developed by Maitland and Maitland,[3] and by Li and Rivers.[4]

Ten-day chick embryos are hashed and suspended either in Tyrode's solution or in buffered bouillon prepared from a special peptone,* and to which 0·1 per cent. gelatin has been added. All solutions, both those used for nasopharyngeal washing and for cultivation, contain 1 to 2000 cystein hydrochloride. At all times an effort has been made to protect the agent against the deleterious action of peroxides. The cultures were incubated under vaseline seal at 37° C. for from four to nine days.

The material used for cultivation was obtained in the following manner: nasopharyngeal washings were made from a patient with a typical cold of more than moderate severity. The washings were passed through a Seitz filter and preserved at ice-box temperature under vaseline seal in the special peptone broth described. On the ninth day of preservation a volunteer was inoculated intranasally, and within 24 hours developed typical symptoms of the common cold. As soon as the signs of the disease were well marked, nasopharyngeal washings were prepared in the usual manner and preserved for five days at ice-box temperature. After this interval a second volunteer was inoculated, who also developed symptoms of a cold within the usual incubation period. Nasopharyngeal washings were again prepared, filtered through a Seitz filter, and concentrated by vacuum distillation. After ten days' preservation at ice-box temperature a third volunteer was inoculated. This individual developed a cold of unusual severity, possibly indicating an accession of virulence by the virus. Nasopharyngeal washings were prepared from this individual after the usual interval, filtered through a Seitz filter, concentrated seven times by vacuum distillation, and preserved for five days at ice-box temperature. After the lapse of this interval 0·25 c.cm. of the concentrated material was inoculated into tissue medium of the nature described. The culture was incubated for five days at 37° C. At the end of this time a human volunteer was inoculated and within the usual incubation period developed a cold with symptoms of rather a mild character.

From this time on the material was carried in tissue medium and transferred at intervals of from three to nine days. We believe the preferable interval between transfers to be four days. From time to time cultures were chosen for the inoculation of experimental subjects. The third culture representing a dilution of the original material of approximately 1–2000 was inoculated into a chimpanzee. This animal developed symptoms of a cold after an incubation period of four and a half days. An uninoculated companion animal kept in the same cage developed symptoms of a cold at the same time. The sixth culture, representing a dilution of the original material of approximately 1–2,000,000, was inoculated into three human volunteers. Of these, two developed after 24 hours typical colds of moderate severity. The tenth culture, representing a dilution of the original material of approximately 1–20,000,000,000, was inoculated into three human volunteers. Of these, one developed such mild symptoms of respiratory infection as to be considered doubtful. The twelfth culture, representing a dilution of approximately 1–2 trillion, was inoculated into three human volunteers, and of these one developed a cold of mild symptoms. The fifteenth culture, representing a dilution of approximately 1–2 quadrillion, was inoculated into three human volunteers. Of these, two developed colds of unusually severe symptoms, complete nasal obstruction, frontal headache, malaise, loss of appetite, nasal discharge, and pronounced cough. Nasopharyngeal washings were prepared from these two individuals, filtered through a Seitz filter, and concentrated by vacuum distillation. Two human volunteers were inoculated after a short interval with these concentrated filtrates and within 24 hours both developed colds, one with mild symptoms and the other with the typical features of a head cold.

DISCUSSION.

The evidence presented by these experiments indicates that the virus of the common cold survives for a considerable length of time after removal from the human nasopharynx, and that the agent reproduces itself in vitro when cultivated in suitable tissue medium. The total duration of life of the culture virus from the time of removal from the human subject has been 74 days. The final dilution of the original material is so great as to rule out conclusively the presence of any significant amount of the original virus. Controls of the constituents of the medium and of the tissue medium have been negative. In one instance when a volunteer received active culture heated for half an hour at 80° C. there appeared symptoms of upper respiratory irritation which lasted for less than 24 hours.

From these studies the conclusion may be drawn that one type of acute upper respiratory infection is caused by a filtrable virus. In addition to initiating the symptoms of infection this agent may be considered to provoke increased activity of any potential pathogens that may happen to be present in the respiratory tract, and, furthermore, to render the respiratory tract susceptible to implantation by pathogenic organisms from the exterior. An interesting observation in connexion with this point of view is that in individuals stigmatised with rheumatic disease many times a recrudescence of the rheumatic process is occasioned by an attack of the common cold. From the above observations the inference may be drawn that the virus of the common cold in the individual plays the double rôle of initiator and promoter of upper respiratory infection.

The significance of this virus in the ætiology and epidemiology of respiratory infection of the community as a whole is still obscure, but certain interesting facts indicate its great importance. Studies [5] of outbreaks of common cold in representative population groups show a high morbidity-rate for this infection of cyclic character. The peaks of incidence are three in number, and occur in the early fall months, September and October, the mid-winter months, January and February, and the spring months, April and May. The character of the different outbreaks varies in severity, and there seems to be a progressive increase in the seriousness of the secondary infections of the respiratory tract as the winter advances into spring. For example, the amount of absenteeism from work is much greater during the January outbreak than during the October outbreak. The incidence of the pneumonias is higher during the *former period than* during the latter. Furthermore, since the pandemic of influenza in 1918, all outbreaks of influenza in New York City have occurred in the early months of the year, thus coinciding in time with one of the periods of maximum incidence of the common cold. Studies conducted by us have shown, considering the respiratory year, so to speak, as running from September to June, that as this year advances there is an increasingly wide distribution in the nasopharynx of healthy individuals of such potential pathogens of the upper respiratory tract as pneumococcus, *B. pfeifferi*, and *S. hæmolyticus*.

---

* Especially prepared peptone obtained through the kindness of Dr. René Dubos, of the Hospital of the Rockefeller Institute.

The interpretation of these observations is not yet clear, but it seems not unlikely that as a consequence of the repeated cycles of common cold throughout the respiratory year an increasing opportunity is afforded the potential and sometimes secondary pathogens of the respiratory tract to cause infection. As a result of this their distribution is promoted and their virulence perhaps enhanced. This type of associated activity makes it seem not unlikely that certain outbreaks of so-called influenza or grippe may result from the coincidence of an epidemic outbreak of the common cold, with a period of wide distribution and increased virulence of the well-recognised pathogenic organisms of the upper respiratory tract. However this may be, there is no doubt that the virus of the common cold plays a most important rôle in promoting respiratory infection in the community as a whole, in addition to its obvious significance in respiratory infection in the individual.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

TROPICAL MEDICINE AT THE COLONIAL EXHIBITION.

THE Journées Médicales Coloniales at the Colonia Exhibition at the end of last month (July 22nd–31st constituted a veritable international conference on tropical medicine. It opened in the great hall of the Cité des Informations under the chairmanship of Marshal Lyautey, who paid this tribute to medicine —that in many cases it had been able to replace battalions in the pacification of new countries. Prof. Tanon outlined the programme of the conference, which he hoped would prove a milestone in the evolution of tropical hygiene. The number and standing of the official delegates from Great *Britain* and her dependencies showed how great was the importance attached to it in this quarter.

Among the numerous and most interesting reports presented was one by Dr. A. Thiroux on birth-rate and infant mortality in the French colonies. It was based on the study by Colonel Cazanove, presented in 1930 to the Office International d'Hygiène Publique. The birth-rates showed remarkable local differences, ranging as they did from 7 to 84 per 1000, *the last-named* prodigy of fecundity being claimed by a district in the Cameroons. The infant mortalities also showed wide fluctuations, ranging from 155 to 319 deaths in the first year of life *for every 1000 live* births. He headed the list of the causes of death in infancy with malaria, giving as an example the findings in Antananarivo of malarial enlargement of the spleen in 77 per cent. of the school-children. In a paper on sleeping sickness in French equatorial Africa, Dr. A. Sicé stated that among 830,448 natives inspected in 1929 the morbidity-rate from this disease was about 4 per cent. After enumerating a list of measures and remedies, he concluded that trypanosomiasis has ceased to be a danger for the economic future of French equatorial Africa. Other speakers dealing with trypanosomiasis in French occidental Africa stated that on the whole, and since 1920, this disease has waned, although here and there it has gained new ground. The reports on the prevention and treatment of leprosy showed how great have been the changes of late years in the attitude of medical science towards it. Dr. Stevenel discussed recent experiences with chaulmoogra oil, the only drug which, in his opinion, has hitherto proved indubitably effective, and with regard to prophylactic measures he insisted that they should not be more cruel than those now recommended in tuberculosis. Dr. Thomas Cochrane, discussing the prophylaxis of leprosy in the British African Colonies, also showed how impossible it would be, physically and financially, to apply measures of strict isolation to the five to ten million lepers supposed to be living in the world to-day.

A CONGRESS OF DENTISTS.

The eighth International Dental Congress, which opened on August 2nd at Versailles, under the patronage of the President of the Republic, was held during the following days in the Grand-Palais in Paris. More than 3000 persons took part, and 33 governments sent official representatives. The President, Dr. G. Villain, in his opening address, traced the history of dentistry since the congress last sat in Philadelphia in 1926. Up till then dentistry had been overshadowed by a vogue which traced an infinite number of evils to the teeth themselves, the medical profession in many countries taking such a wholesale and severe attitude towards the alleged sins of the teeth that their extraction had become the most habitual therapeutic act, and the dentist had found himself "demoted" to the elementary rôle of tooth extractor. Dr. Villain considered that the fortunate passing of this crisis had led, in the course of the last five years, to the development of research into prosthetic restoration. Another important development in dentistry during the last five years was, in his opinion, the work of Mellanby and others on the relation of caries to metabolism and diet.

THE LICENSED BROTHEL.

It *is* pretty safe to prophesy that if and when the *official* regulation of prostitution is discontinued in France this change will be due not so much to the experience of other countries as to the tentative experiments now being made here and there in France itself. The abolition of the controlled brothel in Grenoble is being followed with the keenest interest by the abolitionists and their opponents, who keep up an interesting correspondence in the *Siècle Médical.* Meanwhile the town of Nancy has decided to follow suit, and its mayor has issued an order closing all the *maisons de tolérance,* whose licences are to be withdrawn on Nov. 1st.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

POLIOMYELITIS.

SOMETHING like an epidemic of poliomyelitis has made its appearance in certain of the Middle Atlantic States and shows a tendency to spread westward. The increased incidence was first noted in New York City during the week ending July 25th, in which 195 cases were reported, as compared with 35 cases for the first six months of the year. A sharp rise in incidence was also reported at the end of July by the Connecticut State Department of Health. During the first half of August the incidence of poliomyelitis in the state of Illinois has been three times the expectancy. Although this does not represent a rise comparable to that in the east it shows a tendency for the disease to spread along the line of travel.

Various State health departments have taken measures to meet the threatened attack. Connecticut, New York, and Illinois are providing consultant diagnostic service and immune serum. In Connecticut serum has been obtained from the Newington Home for Crippled Children. In New York State appeals for blood from those who have had the disease have been broadcast, and Governor Roosevelt has set an example by giving, for the second time, some of his own blood. Hospitals are advised to be prepared to take cases under conditions of isolation and to provide themselves if possible with a Drinker respirator for the treatment of cases with bulbar paralysis.

A conference of New England health officials was held in Boston on August 3rd. At its close a statement was issued warning parents that "Perhaps the most suggestive early sign warranting attention is a stiffness of the spine and neck in a sick child, best shown when the child is asked to sit up in bed and bend the head forward between the knees. Infantile paralysis," it is stated, "is spread by personal contact with patients or healthy persons carrying the infection. Children's contacts therefore should be restricted to the usual groups of associates. Camps and children's institutions are advised to discourage visiting by outsiders. Children now in camps under controlled conditions and observation had better stay there rather than increase their contacts by leaving." Even as far west as New Mexico warning circulars have been sent to the medical profession advising of the chief diagnostic symptoms of poliomyelitis in the prodromal stage and of the significant laboratory findings in these early cases.

DEATH OF LEE KAUFER FRANKEL.

By the death in Paris on July 25th of Lee K. Frankel, Ph.D., America loses one of its outstanding leaders in public health. He was for nine years manager of the United Hebrew Charities of New York, and then for a short time special investigator for the Russell Sage Foundation. But it was in 1909, when he joined the staff of the Metropolitan Life Insurance Company and organised its welfare division, that the nation as a whole began to feel the impress of his influence. The work which he organised, both in educational literature and particularly in the public health nursing service, was quite original as a contribution of insurance practice and extremely influential in promoting public health. Dr. Frankel was vice-president of the National Tuberculosis Association in 1914, president of the American Public Health Association 1919, and of the National Health Council, child of his own organising genius, from 1923 to 1926. The Framingham tuberculosis demonstration was another invention of his fertile mind. Numerous public health organisations benefited from his advice. At the time of his death he had recently completed a survey of social insurance in Europe.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

POOR-LAW SALARIES IN COUNTY WEXFORD.

THE County Wexford board of health has been informed by the Department of Local Government and Public Health that owing to the continued neglect of the board to fix a suitable scale of salaries for the dispensary medical officers of the county, the Minister felt constrained to issue an order fixing the salaries of these officers. The salaries were now determined to be on a scale beginning at £200 a year, and increasing by £5 a year to £300 a year, to be applied retrospectively. The order was not to affect any existing officer adversely. The sealed order was enclosed. The order affects eight medical officers, and brings about a total increase of £390 a year. With a scale of salaries established in Wexford, there is now a scale in force in every county in the Irish Free State. There are, however, considerable differences between the scales in different counties.

THE DERBY SWEEPSTAKE.

The Irish Hospitals Trust published last week a financial statement concerning the sweepstake on the Derby. The total receipts, after deducting £38,000 for sellers' prizes, came to £2,789,696. Of this sum £697,424, or 25 per cent., was distributed to the hospitals; £1,902,500, or 68·2 per cent., was spent in prizes; and £189,772, or 6·1 per cent., went in expenses. Of the latter sum, £58,266 was paid to Hospitals Trusts, Ltd., as promoters of the sweepstake. The grants to hospitals were divided among 34 institutions. The highest grant was £48,819, or 7 per cent. of the total, which was given to the Royal City of Dublin Hospital. Five hospitals—Sir Patrick Dun's, Meath, Richmond, Cork Street, Coombe—got 6 per cent., or £41,845 each. Various grants were given to the others, the smallest grants, 0·5 per cent., or £3487, reaching the Martin Hospital, Portlaw, and the Drogheda Memorial Hospital, The Curragh. Preparations are far advanced for the sweepstake on the Manchester November Handicap. The list of participating hospitals has not yet been compiled.

THE METROPOLITAN HOSPITAL.—The annual report of this institution (Kingsland-road, E.) states that serious defects in the fabric have been discovered. The fire staircase must be renewed at once, and fractures in the main structure, necessitating repairs of considerable magnitude, must be put in hand shortly. The cost of these works will be between £6000 to £7000, and an effort is to be made to raise this sum before launching the general appeal that is in contemplation. When that appeal is made over £50,000 will be asked for to pay off the debt of £18,000 on the nurses' home and to meet the cost of essential improvements.

PANEL AND CONTRACT PRACTICE

ETHICS OF CONSULTATION.

At the annual panel conference in October last attention was given to smooth working of additional benefits under the N.H.I. Acts, and particularly to the relation of panel practitioner to consultant in his various guises. It seemed to the representative of East Sussex for instance that his patients were apt to disappear into sanatoriums, rheumatic clinics, and other forms of special treatment, and return to him later without any information on treatment received or advice given. He thought, and the conference agreed with him, that the accepted ethics of consultation should apply to all these situations in insurance practice. The matter was referred to the central ethical committee of the British Medical Association which decided that the rules drawn up for private practice applied equally well to insurance practice if read in conjunction with the rules guiding the practitioner when called upon by a third party to make an examination. The two sets of rules which are of fundamental importance appear as Appendix C to the report of the Insurance Acts Committee printed in the Supplement to the *British Medical Journal* for August 29th. In these rules the term "consultant" is to be understood as meaning any practitioner who is called upon by the patient or by any person acting on behalf of the patient, to advise in special circumstances with regard to a patient who is already under the care of another practitioner, that other being referred to as the "attending practitioner."

WHERE CONSULTATION IS REQUIRED.

In the interests alike of the public and of the medical profession, it is the duty of a medical practitioner to accept the opportunity of consultation, especially upon obscure and difficult cases, or where the patient or his friends desire it.

In the following cases it is especially the duty of the practitioner in attendance to endeavour, if practicable, to obtain the assistance of another opinion:—

(*a*) When a question arises of the propriety of performing an operation or adopting some course of treatment which may be dangerous to life or permanently injure the condition of the patient, especially if the condition which it is thought to relieve by this treatment be not itself dangerous to life.

(*b*) When a question arises of destruction of a fœtus, or unborn child, in the interest of the mother, especially if she is not in labour.

(*c*) When the practitioner in attendance is in doubt either as to the diagnosis or as to the treatment to be followed, and delay in arriving at a decision might be dangerous.

(*d*) When there is evidence of anxiety on the part of the patient or his friends as to the correctness of a diagnosis or of the treatment pursued.

(*e*) When the attending practitioner has reason to suspect:—

(i) Performance of an illegal operation.
(ii) Administration of poison.
(iii) Commission of any other criminal offence.

CHOICE OF CONSULTANT.

It is expedient in the interests of the patient that the choice of consultant should usually be left to the practitioner in attendance. Nevertheless, a practitioner is not justified in refusing to meet a consultant selected by the patient, or the patient's friends, unless he is satisfied that the proposed consultant is not qualified by knowledge or special experience to advise upon the case, or that he is one of whom he is debarred from meeting. It is the duty of a practitioner to refuse to meet in consultation:—

(*a*) An unregistered person.

(*b*) A practitioner whose exclusive profession of any peculiar system of treatment would render consultation futile.

(*c*) Any practitioner whose conduct has, after due inquiry, been declared by some recognised body of the medical profession to be detrimental to the honour and interests of the profession, such declaration not having been made inoperative by any subsequent pronouncement of the body in question or of any superior ethical tribunal.

PROCEDURE AND ETIQUETTE.

The arrangements for consultation should be made by the attending practitioner. If a practitioner receives an application to act as consultant from any person other than the attending practitioner of the patient, he shall *not* see the patient without the consent of the attending practitioner. The following rules should be observed, unless there is substantial reason in any particular case for departing therefrom:—

(*a*) If the consultation is not held at the patient's house, it generally takes place at the house of the practitioner consulted, who also fixes the hour of meeting, unless otherwise amicably arranged.

(*b*) All parties to a consultation should be punctual. If the attending practitioner does not keep the appointment, the other or others may, after a reasonable time, see the patient, and leave his, or their, conclusions in writing, in a closed envelope addressed to the attending practitioner.

(*c*) Before seeing the patient, the attending practitioner should, as a rule, give the consultant a brief history of the case.

(*d*) On entering the room of the patient, the attending practitioner should precede the consultant, and should, if necessary, introduce him to the patient, and the attending practitioner should be the last to leave the room. The diagnosis, prognosis, and treatment should be discussed in private.

(*e*) The opinion on a case, and the treatment, should be communicated to the patient or the patient's friends by the medical man consulted, in the presence of the attending practitioner.

(*f*) If it is found necessary that the patient or his friends should be made aware of a difference of opinion among the practitioners taking part in a consultation, it is the duty of the consultant, jointly with the attending practitioner, to communicate this information.

(*g*) The practitioner in attendance should ascertain previously, and inform the patient or his friends, as to the amount of the fee, which should be paid to the consultant at the time.

(*h*) If for some reason a personal consultation is impossible, the attending practitioner should write a letter introducing the case, and should courteously and punctually reply to any communication from the consultant, and the latter should write and forward his opinion, along with any prescription he may advise, in a closed letter addressed to the attending practitioner.

(*i*) Arrangements for a future consultation should be left to the initiative of the practitioner in attendance.

RELATION OF CONSULTANT TO PATIENT.

Great care should be exercised in making any observations in the presence of the patient on the nature of the malady, its probable issue, or treatment pursued, and all criticisms or reflections on the practitioner in attendance must be avoided. Differences of opinion, so long as there is final agreement among the parties to the consultation, are not to be revealed, but if agreement as to diagnosis and treatment should not be possible and the consultant is convinced that the future well-being of the patient is concerned in his so doing, he should inform the patient in the manner prescribed above.

It is the duty of the practitioner in attendance loyally to carry out the measures agreed upon at the consultation, and he should refrain from making any radical alteration in such measures except upon urgent grounds or after adequate trial.

In recognition of the position of trust in which he is placed towards the attending practitioner, the consultant must not, by unduly ingratiating himself *or otherwise, attempt to secure for himself a patient*, or the relative of a patient, whom he has seen in consultation, and must exercise scrupulous care to avoid disturbing the confidence of the patient in the attending practitioner.

If the consultant wishes to make any communication with regard to any case which he has seen in consultation, he should only do so through the attending practitioner, and should not discuss the case with the patient or any of the patient's friends, in the absence, or without the consent of, the attending practitioner.

A practitioner who has seen a case in consultation should not supersede the attending practitioner during the illness with regard to which the consultation is held, and, if he be asked to attend or prescribe in any future illness he should only do so after explanation with the attending practitioner, unless circumstances make this impracticable.

Third Party Consultations.

There remains to consider the special case of patients under care of other practitioners. Rules in respect of position of medical practitioners called upon to examine, otherwise than by request of patient or persons acting on patient's behalf, are as follow. They do not apply to certifying factory surgeons.

NOTICE OF VISIT.

The medical inspector should give the medical attendant such notice of the date, time, and purpose of his visit as will afford reasonable opportunity for the medical attendant to be present should he or the patient so desire. Exceptions are :—

(*a*) When circumstances justify a surprise visit.

(*b*) When circumstances necessitate a visit within a period which does not afford time for notification.

(*c*) When the medical inspector, after due inquiry made, has no information as to whether the patient is under medical care.

Where the medical inspector has availed himself of any of the above exceptions, it shall be his duty to inform the medical attendant, if any, of the fact of his visit, and the reasons for his action.

THE VISIT ITSELF.

The medical attendant must not put any unnecessary difficulties in the way of fixing a time convenient to both practitioners. If the medical attendant fails to appear at the time stated, the medical inspector may proceed with his examination forthwith. The medical inspector must not, without the consent of the medical attendant, do anything in the course of his examination which involves active interference with the treatment of the case. Where the medical attendant fails to communicate with the medical inspector, the medical inspector shall at his discretion and subject to the consent of the patient, make any examination he may consider necessary.

THE REPORT.

The medical inspector must not make any comments to the patient which are of the nature of criticisms of, or reflections upon, the treatment, nor must he express, without the concurrence of the medical attendant, any opinion to the patient as to the ætiology, diagnosis, or prognosis of the case. His duty is strictly confined to examining into such matters as are necessary for the purposes of his report, and reporting to his employer, and to his employer only, his conclusions from such examination.

If the medical inspector finds it necessary to report to his employer that any modification in the treatment which is being carried out is, in his opinion, necessary to the more rapid recovery of the case, he shall, if possible in the first instance, so inform the medical attendant.

MEDICINE AND THE LAW.

Professional Registration—The Architects' Success.

STATUTORY registration, a principle of proved value for establishing professional standards in the public interest, has now been applied to architects. The Medical Act, rather than the Dentists Act, is the precedent which has been followed; that is to say, there will be a monopoly of the title of "registered architect," but no monopoly of practice; Parliament, therefore, has not needed to define the practice of architecture. On the other hand the Dentists Act, rather than the Medical Act, is followed in the provision which allows a right of appeal to the High Court to a person aggrieved by a decision to remove his name from the register or by temporary disqualification. Among other parallels or variations we may note that an architect's name may be removed from the register on conviction of a criminal offence or for "conduct disgraceful to him in his capacity as an architect." The traditional phrase "infamous conduct," sometimes a source of popular misunderstanding in relation to medical practitioners and dentists, has thus been dropped, and the language of the Veterinary Surgeons Act has been adopted instead. Such conduct in an architect will be referred to a disciplinary committee, which is assured of a legal element in its quasi-judicial functions because, in addition to members appointed by the Office of Works and the Ministry of Health, there are to be two members nominated by the President of the Law Society. The qualifications for registration include anyone who applies within two years, and satisfies the Architects' Registration Council that at the commencement of the Act—i.e., Jan. 1st next—he is or has been practising as an architect in the United Kingdom. There will thus be a class of "1931 architects," corresponding to the "1921 dentists."

The architects' profession is to be congratulated on obtaining this degree of statutory regulation. The establishment of a single central supervising body is valuable in itself. Much may be done even by a system of mere voluntary registration such as has been initiated lately, for instance, for biophysical assistants in the hope of ridding the public and the medical profession of quackery in certain physical treatments. Statutory sanction gives, of course, a national recognition as well as supporting the system of registration by the infliction of penalties for its abuse or infringement.

MOORFIELDS EYE HOSPITAL.—The annual report of the Royal London Ophthalmic Hospital, Moorfields, states that last year 2547 in-patients and 52,372 out-patients were treated, and that the income was £34,279 and the expenditure £32,480. The out-patients' department urgently needs enlargement; the cost will be £40,000, towards which £13,000 is available.

CORRESPONDENCE

IMPRISONMENT FOR MENTAL DISORDER.

To the Editor of THE LANCET.

SIR,—The letters of Prof. Millais Culpin (p. 373) and of Dr. Russell Brain (p. 426) raise an issue in which the National Council for Mental Hygiene is especially interested. The Council has in the course of the last few years collected records of a not inconsiderable number of cases in which the magistrates have refused to take into consideration the evidence of doctors as to abnormality in the mental condition of offenders, or have refused to permit examination by medical experts where this has been asked for in the interests of the offender. In addition to these there have been cases where the existence of an abnormality was undoubted and in which the magistrate has passed sentence without taking into consideration the medical aspect of the case. Three instances may be cited:

(1) A man of middle age had repeatedly written letters of an abusive nature to the municipal authorities accusing them of appropriating land which formed a part of his property. Medical evidence was adduced to show that the man was suffering from delusions of persecution. The magistrate sentenced the man to a term of imprisonment with the comment that "It was the function of the Court to cure delusions."

(2) A boy of about 17 years of age, described as of a moody and seclusive temperament and who had on several occasions previously behaved in a sufficiently bizarre manner to cause comment, set fire to some ricks. No motive was found and the boy was unable to give any reasonable explanation for his act. No investigation of the boy's mental state was made and he was duly sentenced.

(3) An educated woman of early middle age, a school teacher with an excellent record, was caught stealing some small articles in a store. No investigation was made into her mental condition although it was clearly established that she had no real need of the articles and could easily have paid for them. In passing sentence of imprisonment the magistrate said that although she was a woman of education and means she had yet behaved like a common thief, a fact which he considered an aggravation of the offence.

Comment on these cases is superfluous. On the other side of the picture and to show the value and importance of obtaining expert opinion the following cases which passed through my own hands may be cited:

(1) A married woman of early middle age, whose husband was of the respectable working class, was charged with writing abusive letters to certain public men making offensive allegations. Her previous record was blameless. The magistrate referred her for investigation to be made into her mental condition. It appeared that she was now at the menopause, and that for the last two years had been showing emotional instability and character changes during her periods, at times becoming definitely deluded, with ideas of persecution. She undertook to attend the hospital regularly for treatment and the case was dismissed. Needless to say there has been no recurrence of the offence.

(2) A boy, aged about 18, was charged with attacking a girl in a quiet street and trying to snatch her handbag. The boy's father, on his own initiative, brought him up to the hospital clinic before the trial for investigation into his mental condition. The boy had a perfectly satisfactory record at school and at home. He was, however, rather afraid of his parents and was latterly showing evidence of impaired memory and undue shyness and nervousness. His employment was uncongenial, and he was told to go and interview a new employer. Afraid to do this he loitered about, and forgetting where he had left his bicycle wandered out of the town. Towards evening he found he had no money and was some distance from home. He ascribed snatching the handbag to an unreasoning impulse. He finally returned home in a dazed condition and in great mental distress at what he had done. An uncle now offered the boy a post in the country. The girl did not wish to prosecute. A letter was written to the magistrates putting the medical factors of the case before them. The case was dismissed and the boy is now in the country and doing well.

At the biennial conference of the National Council for Mental Hygiene, held in May last, a general demand made itself felt for increased facilities for the education of magistrates on the subject of mental hygiene. The Council in its lecture courses held twice yearly always includes some aspect of this problem. The Tavistock Square Clinic for Functional Diseases has given lectures for magistrates and the National Council is arranging further lectures in the immediate future. One of the difficulties, however, is to procure the audience. Many magistrates, are busy people, and for those in the provinces especially it is difficult to afford adequate facilities, even if they were prepared to make use of them. The new Mental Treatment Act and the increase of out-patient clinics for the treatment and investigation of cases of emotional instability and early mental disorder should, however, in course of time provide a place to which doubtful cases can be referred in every area. It is important to educate the public as well as the magistrate up to the use of these invaluable facilities.

I am, Sir, yours faithfully,

DORIS M. ODLUM,

Hon. Sec. for Propaganda, National Council for Mental Hygiene.

August 23rd, 1931.

5

TUBERCULOSIS IN INFANTS.

To the Editor of THE LANCET.

SIR,—In your annotation of August 15th (p. 363) on Tuberculosis in Russian Infants, attention is drawn to the early appearance of this disease. It is often assumed in England that if a baby is breast-fed by an apparently healthy mother, tuberculosis need not be feared. Two cases recently encountered show that this may be a very erroneous idea, and that tuberculosis may be met in infants where there is no suggestion of the infection in either parent, or either family, nor any evidence of contact during the few weeks of life with any affected person. The conclusion to be drawn is that in some cases, even with no family history of tuberculosis, the susceptibility is very high, and massive infection is therefore unnecessary.

An entirely breast-fed infant, aged 43 days, weighing 7 lb. 1 oz. was admitted to Booth Hall Hospital for Children as a weakly infant with a history of having on the day of admission suddenly commenced to droop, the child having been perfectly well until then. Birth weight was 6 lb. 2 oz. When five weeks old the weight was 7 lb. 6 oz. and two days before admission 7 lb. 5 oz. The mother was admitted to feed the infant. There was slight vomiting on arrival, but no more until once 11 days later. There was no diarrhœa. A week later the child appeared hungry and lively, test feeds showing that he was obtaining about 5 oz.—a considerable amount for a seven weeks' baby. The next day one feed was refused, the general condition being poor. On succeeding days the temperature rose to 99° F., to 100°, and to 101°, dropping abruptly on the next day. X ray of the chest showed definite parenchymatous infiltration of both lungs, and the child was considered to be suffering from broncho-pneumonia. On the day the temperature fell the child had to be fed from a pipette with milk taken from the breast, and about 10 o'clock died quite suddenly. The Wassermann test was negative. Examination post mortem showed generalised miliary tuberculosis involving lungs, spleen, and liver, but not the brain.

In this case there was no direct evidence of parental infection; but the mother, during her pregnancy, drank unboiled milk from a source which is frequently found to be tuberculous. The mother was requested to return so that a sample of her breast milk might be examined for tubercle bacilli, but she failed to put in an appearance. Thanks to the kindness of Dr. D. P. Sutherland, senior tuberculosis officer for the City of Manchester, and Dr. Norah Smith who is in charge of the maternity and child welfare department, an extremely complete investigation was made into the previous history of this case as regards possible contact with a known case of tuberculosis, or the ingestion of any contaminated milk by the patient, with negative results.

Whilst interest was still aroused by this case, a similar one, as so frequently happens, came to my notice.

A child, aged 8 months, still on the breast, was admitted on account of gastritis and constipation. The combination is not usual, and progress was not satisfactory, there being continuous loss of weight. Vomiting and constipation persisted, and on the eleventh day after admission there was rigidity of the neck muscles, and an occasional squint, a note being made "the child does not appear dyspeptic; looks more like cerebral tumour." Examination of the eyes next day showed slight blurring of the nasal side of both discs, the vessels being normal. Lumbar puncture gave 20 c.cm., of clear colourless fluid under pressure, with no improvement in the condition. Examination of the cerebro-spinal fluid showed that the cells were increased to 29 lymphocytes per c.mm., the protein being 120 mg. per 100 c.cm., but no tubercle bacilli were found. Progress was now much more definitely suggestive of meningitis, and further lumbar puncture gave 65 lymphocytes per c.mm., protein 200 mg. per 100 c.cm., and tubercle bacilli were found. The child died on the nineteenth day, examination post mortem showing one caseous lobule and small discrete tubercular nodules in the lower lobe of the left lung, and hilar and bronchial glands enlarged, caseous, and softened. The brain showed evidence of tuberculous meningitis.

Investigation of the previous history of this case by Drs. Sutherland and Smith showed that the child had been breast-fed, but that after six months old it occasionally had crusts dipped in unboiled milk. This milk-supply has been found to contain tubercle bacilli several times, but on no occasion this year. The mother stated that she was in the habit of taking the child to the "pictures." The baby also had teething powders mixed with milk, but the child had not been in contact with any known case of tuberculosis, nor are the parents considered tuberculous. Here again though there was no family susceptibility, and though the infant was continually breast-fed, very slight exposure to infection was sufficient to give rise to a pulmonary infection which probably was the origin of the meningitis.

I am, Sir, yours faithfully,
J. D'EWART, M.B. Lond.,
Medical Superintendent, Booth Hall Hospital
August 25th, 1931. for Children, Manchester, E.

TOURNIQUET PARALYSIS.

To the Editor of THE LANCET.

SIR,—I wish to associate myself with the views expressed by Mr. N. L. Eckhoff in your issue of August 15th (p. 343). The advantages of a bloodless field are, as he says, so many, it is unnecessary to stress them. It is in the manner of procuring this that the difficulty lies. I have long realised that when I apply a tourniquet (a flat Martin's bandage) I am risking a paralysis, and recently, wherever possible, I have used a pneumatic tourniquet; but up to the present I have not been able to find a really satisfactory one. It slips off, or the valve leaks, or it takes up so much room that it encroaches on the field of operation; in some cases it is not long enough to encircle the limb, and then I have to discard it and continue the operation without, or disarrange everything while the Martin's bandage is applied.

There is not as a rule much difficulty with the upper limb; it is the lower limb which causes most of the trouble. Where the thigh is fat and short, and the operation is on the knee-joint, it is quite impossible to obtain a bloodless field with the pneumatic tourniquet in use—which is a canvas-covered affair, part of a sphygmometer outfit—and one is forced to use the Martin. But the efficient application of even this may be difficult under the circumstances described. Unfortunately my experience with regard to the lower limb has differed from that of Mr. Eckhoff, for I have had a case of paralysis of the peroneal nerve following the application of the "old thick rubber tube" just above the knee. I had to perform an open osteotomy of the upper third of the right tibia for a lady aged 29 who had severe bow legs. Two days later complete peroneal paralysis was discovered. As this did not clear up, I explored the nerve at the site of operation to see if it had been injured, but it was unhurt. The paralysis did not resolve completely for over six months.

One other point. I do not allow any one but myself to apply the tourniquet—keen and enthusiastic residents are apt to apply it too tightly.

I am, Sir, yours faithfully,
PAUL BERNARD ROTH.
Welbeck-street, W., August 24th, 1931.

A REVOLVING SOLARIUM.

To the Editor of THE LANCET.

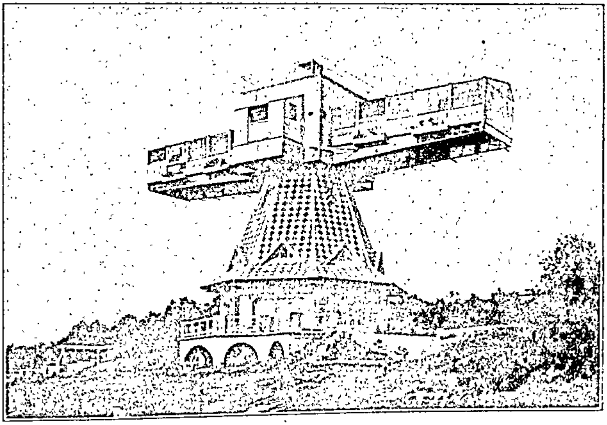
SIR,—The accompanying illustration (Fig. 1) shows a revolving solarium at Aix-les-Bains, France, which is, I am told, the only one of its kind in the world. The designer is Dr. Jean Saidman, director of the Institute of Actinotherapy in Paris, and I am indebted to him for kindly taking me over it.

Situated on a high hill amongst the mountains of Savoy, the solarium is visible a long way off and looks like an enormous aeroplane. On entering the door it seems incredible that such a network of machinery could have been constructed in so small a space. The ground floor consists of a miniature reception room, where the patients are indexed, and the solarium is kept in touch by telephone with the world below. In the middle of the body or tower is the lift, which brings one to the floor where the sun treatment is given. Apart from the reception office are the room of the director, where details of the patients' cases are filed, and here all the treatments are worked out and discussed by him and his able assistants, Dr. Robert and the electrotherapeutist, Mr. Sous. On the ground floor is also a waiting-room, which, like the other rooms, has silver wallpaper, glass doors, and silver chairs—everything to ensure light and brightness.

Proceeding to the top floor one has the sensation of being in the control tower of an aerodrome. In the middle of this floor is a small lounge, where the patients wait until they have their treatment; on the other side of that landing is the real heart of the whole mechanism, where the movements of the solarium are controlled so as to obtain the maximum intensity of the sun. The rays are measured by a special instrument, and the solarium is easily turned on its axis by an electromotor.

Dr. Saidman's method is based on three main principles, as follows: (1) The variations of the intensity of the constituents of sunlight (ultra-violet, visible, and infra-red) should be taken into account. (2) In ordinary sunlight treatment the patient lies flat on a couch and receives the rays obliquely; whereas in the solarium he is so placed that the rays fall perpendicularly on his body, and this immensely increases the amount of energy received from the rays. (3) Usually, sunlight treatment is prescribed without any previous measurement of the patient's tolerance; but here a test for the sensibility of the skin is done as a precaution.

FIG. 1.

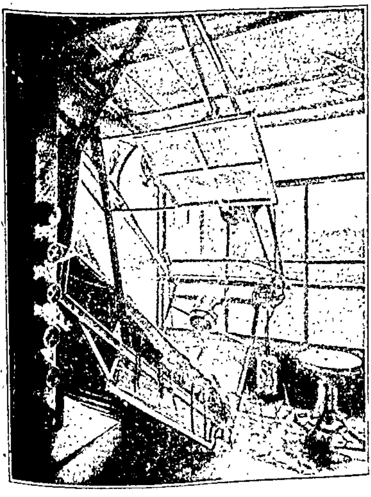


View of the solarium.

The treatment is given in the wings, which are composed of five rooms each. Each room or cabin, as shown in Fig. 2, has a couch which is tilted obliquely for the reasons already indicated. The sunrays are reflected on a special glass which concentrates them upon the patient. In one special cabin, however, it is possible to shut out all ordinary light and only ultra-violet rays are used.

While having treatment one has a magnificent view of the mountains, which naturally improves the therapeutic condition. Afterwards a cold douche is given, or a rub-down with eau-de-Cologne. Each cabin is in touch with the control room by telephone, and each amount of irradiation given to the individual patient shown on special meters. There is also a clock in each cabin, so that the time occupied in treatment is obvious at a glance. The risk of overdosage is much minimised by the preliminary "skin dosage sensibility test." On days when Nature does not supply sufficient sunlight, use is made of artificial sunlight by means of mercury-vapour lamps, of special pattern designed by the director of the solarium.

FIG. 2



Part of a treatment room.

Mostly during the treatment the patients drink the waters of the Source Saint Simon, which is one of the principal waters of Aix, and rises far away in the mountains. It is an alkaline water with diuretic action.

One floor lower than the cabins there is a very elaborate X ray plant generating 300,000 volts, which is used for deep X ray therapy; it has a very favourable effect on rheumatic affections of the joints. The patient is not in the same room as the X ray tubes, so there is no possibility of receiving electric shocks, and he is not made anxious. In order to achieve this he is placed on a special couch in the room below (on the ground floor) and his couch is pulled up to the ceiling. The rays are conducted to an opening in the ceiling, and the only thing the patient notices is the noise of the X ray plant above, which is not very great.

The solarium allows of all the applications of heliotherapy, but is primarily intended for the treatment of certain forms of rheumatism and arthritis. Neuralgias, cellulitis, and myositis are also benefited. The rays often reduce subcutaneous infiltrations and overcome muscular contracture. Synovitis and arthritis with fluid on the knees are also successfully treated in the solarium, and also old fractures, osteomyelitis, and recurring staphylococcal infections.

A visit to the solarium at Aix should be of great interest to those practising heliotherapy, for there is no doubt that with the principles adopted the best use can be made of sunlight treatment.

I am, Sir, yours faithfully,
HERMAN S. N. MENKO.

Northwick-terrace, N.W., August 8th, 1931.

ADMINISTRATION OF CALCIUM.

To the Editor of THE LANCET.

SIR,—In his note on Intramuscular Injections of Calcium in your issue of August 22nd Dr. Izod Bennett recommends the use of a solution of calcium gluconate and lævulinate. For some years past in cases which have needed calcium and where for any reason the intravenous route has been deemed inadvisable, I have used injections of calcium gluconate (Sandoz) intramuscularly. In several hundred injections which have been given I have had no case of necrosis. The dose I have commonly used has been 10 c.cm. of a 10 per cent. solution. I have often found it of value to combine this therapy with massive doses of calcium gluconate and lactose on an empty stomach; 1 drachm of calcium gluconate and 1 drachm of lactose in a suitable vehicle is of great value and there is no doubt, as many recent workers have shown, that lactose assists the absorption of calcium. I have not found the oral administration of calcium very helpful in the small doses which are often suggested. In cases of chilblains, urticaria, hay-fever, and even in the parkinsonism following encephalitis lethargica I have had good results by these methods. I believe—and I have had some radiological evidence to confirm this—that the small hard tablets of calcium preparations sometimes pass unaltered through the intestine.

I am, Sir, yours faithfully,

Harley-street, W., August 27th, 1931. GERALD SLOT.

FISSURES AT THE ANGLES OF THE MOUTH.

To the Editor of THE LANCET.

SIR,—In the excellent paper by Dr. Daniel T. Davies on simple achlorhydric anæmia, published in THE LANCET on August 22nd, mention is made of cracks and fissures at the angles of the mouth as occurring in this disease. I have noticed this physical sign for many years in patients suffering from all sorts of diseases, and sometimes none at all, who all had one thing in common—viz., large artificial dentures. And it is the daily taking out and putting in of these plates which cause and keep up the cracks, where this is done carelessly. After the patient has been advised to exercise great care in manipulating the plates so as not to overstretch the mouth, the cracks soon heal.

I am, Sir, yours faithfully,

Leeds, August 30th, 1931. HERBERT J. ROPER.

SYPHILIS AND YAWS.

To the Editor of THE LANCET.

SIR,—I have no wish to prolong this correspondence, but I should like to point out the microscopical differences between syphilis and yaws. These seem to me to settle the whole question. W. Fox (*Brit. Jour. Ven. Dis.*, 1928, iv., 68) came to the conclusion that the histology was a complete answer to Hutchinson. J. M. H. Macleod (*Brit. Med. Jour.*, Sept 21st, 1901; Practical Handbook of the Pathology of the Skin, London, p. 200) sets out these differences. In yaws the cellular infiltration is not clustered round the vessels, as in syphilis, and there are no multinuclear cells, giant cells, or intracellular hyaline degeneration as in yaws. So far as the fibrous stroma is concerned, rarefraction of collagen is more marked in yaws, and in that disease there is no organisation or colloid degeneration such as occurs in gummata. The vessels in yaws show no proliferative changes in walls and endothelium as do those in syphilis. In yaws there is a marked proliferation and downgrowth of epithelium with great thickening of the horny layer, such as does not occur in syphilis.

I am, Sir, yours faithfully,

Municipal Clinic, Salford. E. TYTLER BURKE.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lts. A. D. Sinclair to *Centurion*; R. M. B. Lowis to *Moth*; and J. W. L. Crosfill to *Fowey*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Commr. H. Winstanley to *Victory* for Haslar Hospital.

Proby. Surg. Lts. J. F. Heggie and F. T. Land to *Victory* for Haslar Hospital; G. E. W. W. Bayly, entered as Proby. Lt., and attached to List 1, Severn Divn., outlying unit at Newport.

Proby. Surg. Sub-Lt. B. R. Alderson to *Pembroke*, for R.N. Barracks.

Surg. Sub-Lt. A. P. Trimble to be Surg. Lt.

Surg. Sub-Lt. J. C. Moor to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

ARMY RESERVE OF OFFICERS.

Lt.-Col. N. D. Walker has attained age limit; Capt. A. L. Taylor, from Supp. Res. of Off., to be Capt.

R. L. H. Minchin to be Lt.

ARMY DENTAL CORPS.

Lt. A. F. D. Shapland resigns his commn.

TERRITORIAL ARMY.

Edward Davies-Thomas to be Lt.

INDIAN MEDICAL SERVICE.

Lt. J. H. Boultbee to be Capt. (prov.).

The promotion of Maj. R. A. Warters is antedated to July 12th, 1927.

The undermentioned officers retire: Lt.-Col. A. G. Tresidder and Maj. R. R. M. Porter, on account of ill-health.

A SOUTH-WESTERN CRIPPLES' TRAINING CENTRE.—Under the auspices of the Plymouth and district cripples' aid committee it is proposed to open in Devonshire a training college for cripples to serve the whole of the south-western counties. At the end of March there were 567 cases under the care of the committee.

FINANCES OF THE BIRMINGHAM HOSPITALS.—An appeal is shortly to be launched for £90,000 on behalf of the General Hospital (£50,000), the Queen's (£30,000), and the Ear and Throat (£10,000). The Maternity Hospital has already made an appeal for £15,000, and the Skin and Urinary Hospital will in the near future ask for the means of increasing the number of its beds from 22 to 50; the Children's Hospital is likewise contemplating an appeal. The General Hospital will have an overdraft of £40,000 by the end of September, and the bank is asking for its reduction, £25,000 of it being unsecured. The number of beds for paying patients is about to be doubled. The Queen's has an unsecured overdraft of £22,000, and all its free investments have been sold to meet the additional maintenance cost of the new surgical block of 120 beds. Last year the Ear and Throat Hospital spent £3303 in excess of its income, £2000 worth of investments have been sold this year, and there is still an overdraft of £3500. The city's hospitals now contain a total of 1734 beds; in 1930 there were 28,825 new in-patients and 190,467 new out-patients. Meanwhile the Lord Mayor, as President, with other officials of the Birmingham Hospital Saturday Fund, which forms an integral part of the contributory scheme, has issued a circular setting out the case for raising the weekly contributions of members from *2d.* to *3d.* It is pointed out that although this fund is the most successful in the world it is inadequate and not self-supporting, and that the contributory patients are costing the hospitals many thousands a year more than they are paying for their treatment. The proposal has been considered by the board of delegates of the Saturday Fund.

PUBLIC HEALTH SERVICES

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1930 statistics of three counties :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Derbyshire .. (624,300)*	16·9	10·1	0·59	1·12	1·3	1·9	61	—	4·1
Surrey .. .. (861,850)*	15·2	10·0	0·62	1·52	1·0	2·1	41	15	3·4
Hampshire .. (432,600)*	16·5	11·3	0·70	1·62	1·1	2·5	44	20	3·8

Registered stillbirths per 100 live births: Derbyshire, 4·6, Surrey, 3·3; Hampshire, 3·3.

* The 1929 populations have been used.

Derbyshire.

Dr. W. M. Ash describes how the new duties of vaccination, infant life protection, and the maintenance of institutions for the physically and mentally sick, placed on the county council by the Local Government Act, 1929, are being dealt with. There are 10 vaccination officers and 81 public vaccinators and the contracts with them have been renewed excepting for the portions of their districts which are without the county boundary. The duty of supervising infants under 7 years of age who are received for reward has been met by appointing the county health visitors as infant life protection visitors. These children numbered 80 at the end of the year. Since the work was transferred from the guardians, parents have been requested, in four cases, to find more suitable foster-parents and in one case a child has been removed from unsuitable guardians by order. The maternity and child welfare committee also supervises the children boarded out by the public assistance committee. It has not been possible for the health committee to take over any of the poor-law hospitals, seeing that only two "institutions" permit of efficient separation of the hospital from the "house," and that there is no superfluity of beds which would allow the institutions to be closed for poor-law purposes. The health committee has not yet consulted the representatives of the voluntary hospitals with a view to formulation of a complete scheme. There has been no important change in the administration of out-relief since the transfer, but all assistance since April 1st has been given to the blind under the Act of 1920. Dr. Ash shows in this, as in previous reports, how an efficient and adequate general hospital system can be built up for the county and he hopes that two hospital services, voluntary and municipal respectively, will not be set up unless they are run in close coöperation and avoid unnecessary competition. He advocates one comprehensive institution for each area as a centre for preventive and curative medicine. The public assistance institutions are not, he says, suitable for the accommodation of many young and middle-aged people suffering from chronic disease and new provision is required for such.

The county mental hospital at Mickleover in 24 wards has accommodation for 388 males and females, and during the year a new up-to- admission block for 100 patients has been opened, which is claimed to be one of the most complete buildings of this type. The county council has no mental deficiency institution and this is a pressing need. At the end of 1930 there were 30 male and 115 female mental defectives accommodated in certified institutions outside the county. The county council scheme for dealing with the 15 isolation hospitals proposes to diminish their number and to have three isolation hospital areas. The formulated principles of the scheme appeared to be generally acceptable to the local authorities, but when it came to deciding as to which hospitals should be closed it was immediately apparent that most of the local authorities qualified their acceptance of the scheme by a proviso that their own particular hospital should not be closed. Dr. Ash points out that the present isolation hospital system does not cover the whole county, does not attract an efficient staff, and does not uniformly adopt immunisation methods against diphtheria and scarlet fever. Further it provides, as a rule, for diphtheria and scarlet fever only save, sometimes, for typhoid fever. There is no provision for the proper nursing of measles and no accommodation for cerebro-spinal fever, encephalitis, dysentery, or poliomyelitis. The provision for small-pox Dr. Ash describes as lamentable, as many of the small-pox hospitals are not reasonably fit for human habitation. He wishes to see a small and a large hospital unit established in each of the three isolation hospital areas for dealing with small-pox. Occasional cases would be dealt with at the small unit and the larger units would be used for other county purposes during inter-epidemic periods. The accommodation for tuberculosis patients was improved during the year by the opening of a new 32-bed pavilion for adults of both sexes suffering from surgical tuberculosis. There is a lack of beds for advanced pulmonary cases, and Dr. Ash suggests that when the isolation hospital service is reorganised the small isolation hospitals, which are closed, could be readily adapted for observation and advanced cases of pulmonary tuberculosis and equipped with modern X ray apparatus. In this manner the needed additional beds for advanced and observation cases could be provided in situations accessible to relatives whilst freeing the sanatorium from the type of case which should not be there.

The county council has two maternity homes and contracts for the use of beds at four others. Each of the eight public assistance institutions also provides maternity beds but frequently in a very wasteful manner. For example, the county maternity home at Ashbourne is by no means fully used but the county council provides a maternity ward at its Ashbourne public assistance institution to which only one case was admitted during the year. A similar state of affairs exists at Chesterfield. The county council contracts for admission of both mother and child to the Royal Infirmary, Derby, in cases of ophthalmia neonatorum. During the year 65 cases were notified, of which 51 were treated at home and 14 in hospital. Vision was impaired in two cases. The antenatal scheme conducted by Miss E. E. Stephens, M.D., at 12 clinics throughout the county has grown rapidly since its inauguration in 1928. The attendances numbered 3117, as compared with 2316 in the previous year. During the year a child guidance clinic was opened at Matlock and is conducted by a member of the medical staff who has had special experience. Children are seen by appointment only.

Of 457 samples of sewage effluents 201 were classified as good, 110 as satisfactory, 48 as unsatisfactory, and 20 as bad. The county council has laid down a standard for the production of clean milk and 1930 the two county sanitary inspectors number of cowsheds with the ers and gave advice, which ies for the clean milk increase and the inspecting judge reported very favourably on the high standard of efficiency attained.

Surrey.

Dr. J. Ferguson says that before April 1st, 1930, there had been in Surrey for 100 years the whole or large portions of 12 poor-law unions, and that the former boards of guardians interpreted the term "destitute" in a wide sense. The county council is anxious to transfer the care of the sick to the public health committee, of the mentally deficient to the mental hospitals committee, and the education of children to the education committee; and the public assistance committee is endeavouring to overcome the difficulties arising from the fact that few of the former hospitals are administered separately from the rest of the institution. The county council has, however, decided to appropriate the Chertsey and Bletchingly institutions for the care of mental defectives. There are in all 10 institutions with 1918 beds and the largest hospital, that of Kingston and district (547) beds) is that which can be most easily adapted for separate use and transferred to the health committee. Towards the end of 1929 the Surrey voluntary hospitals consultative committee, consisting of 24 members representing the governing bodies and medical staffs of the voluntary hospitals, was constituted. At its meetings this committee has made valuable constructive criticisms of the proposals placed before it by the county council. The voluntary hospitals have 1277 beds, the isolation hospitals 633, and the mental hospitals 2507. As regards medical out-relief there has been no change in the policy pursued by the former boards of guardians.

The county health visitors have been approved as infant life protection visitors. On April 1st there were 214 foster mothers who received 304 children, and at the end of the year 406 foster-mothers had given notice in respect of 501 children. The boroughs of Guildford and Wimbledon applied to the Ministry and were appointed local supervising authorities under the Midwives Acts, but a similar application by four urban district councils was not approved. In 1929 a whole-time woman medical officer with special experience in midwifery, &c., was appointed to undertake antenatal work and, at the 15 special clinics throughout the county conducted by her, 977 women attended antenatally and 132 postnatally. The Surrey Council has contracted with the L.C.C. for the institutional treatment of ophthalmia neonatorum. Notifications numbered 46. The cases in the practice of midwives numbered 26, of which 22 were treated at home and 4 in hospital. There were two deaths and vision was unimpaired in the remainder. The result in the 20 cases which occurred in the practice of doctors is not given.

The county council is making arrangements to obtain particulars of the housing situation from the rural districts. On the basis of four persons per house new provision was made for housing 44,000 persons and provision for 22,056 was in hand at the end of the year, but 1436 completed houses and 1288 in course of construction are L.C.C. houses to accommodate residents in the County of London. Mr. F. W. Medlock, M.R.C.V.S., and his four assistants have carried out a quarterly inspection of the herds of the Surrey cowkeepers. The cow examined numbered 67,443, of which 59,415 were in milk. The number of animals dealt with under the Tuberculosis Order was 142, 41 of which were reported to the police as suspect and 101 of which were detected by routine inspection. At the end of 1930 the river Wandle improvement works were practically completed.

In addition to participating in the London V.D. scheme the Surrey Council has clinics at Guildford and Redhill, at both of which the attendances increase. An additional session became necessary at Guildford where there is an ad hoc clinic in the hospital grounds. It is hoped soon to have a third clinic at Kingston and District Hospital. The 14 isolation hospitals have been surveyed and a scheme for the provision of adequate accommodation for the county is in course of preparation. For small-pox the Whitmoor Hospital (10 beds) makes provision for Godalming, Woking, and the urban and rural districts of Guildford, whilst the Clandon Hospital (37 beds) provides for Croydon and the rest of the county. During 1930, 40 cases were admitted to Clandon and the hospital was only closed for eight days during the year. Two of the cases were laundresses infected in the course of their duties. In May to July there was a considerable outbreak of paratyphoid in Barnes—49 cases, of which 16 were males and 33 females. Children and young persons were specially attacked. Fifteen of the patients were severely ill but there were no deaths. The cases were widely distributed over the area and no definite cause for the outbreak was discovered.

Hampshire.

Dr. H. Leslie Cronk reports that up to the end of 1929 grants of £13,761 and loans of £1148 had been paid on 156 cottages under the Housing (Rural Workers) Act, 1926, and that all but six of the 22 rural districts had made applications. Up to the end of 1930 grants totalled £23,231 and loans £2870 with respect to 297 cottages, showing that the Act was more used in 1930 than in any previous year. The extension of the Act and the further provision of £7000 for loans and grants by the county council in February, 1931, will allow further use to be made of this Act, which, says Dr. Cronk, alone enables the preservation of old cottages, that are picturesque assets to the county and can be let at a lesser rental than any new cottage. Under the Housing Act of 1930 a questionaire was issued by the housing subcommittee to obtain information with regard to the housing position in the 22 rural districts. This was followed by a conference in February, 1931, at which 19 of the rural district councils were represented. Exact information was not forthcoming as to how many of the 4087 subsidised houses erected since 1926 were for the agricultural population. Dr. Cronk thinks the problems for the rural districts are provision for housing shortage and the renovation of unfit houses, and that the latter problem can best be dealt with under the Housing (Rural Workers) Act. For any scheme to relieve shortage the county council would have to be satisfied that the houses were needed for the agricultural population.

The accommodation available for the sick in public assistance institutions and the best means of coöperation with the voluntary hospitals are now under consideration. Particulars of the 16 isolation hospitals in the county are given, but nothing can be done in the matter of eliminating unsatisfactory small hospitals and the concentration of beds in as few centres as possible until extensive alterations in the local sanitary areas have been arranged. Small-pox is accommodated at Winchester and at Basingstoke, and plans have been prepared for the improvement of the Winchester hospital.

During 1930 there were 18 antenatal clinics at work which were attended by 412 expectant mothers. In January, 1931, 31 antenatal clinics were established and on May 31st there were 34 in operation, 10 staffed by an assistant county medical officer, and 24 by practitioners of the neighbourhood with special experience. The new cases during the first quarter of 1931 were 382, as compared with 412 during the whole of 1930. Transit is frequently a difficulty for the women and the county council has agreed to pay the fees of general practitioners for domiciliary antenatal visits in such cases. Expectant mothers found antenatally to require dental treatment are treated by the council's dental surgeons. Of 107 mothers needing treatment 97 were actually treated during 1930. The premium to be paid by expectant mothers to ensure against the cost of medical attendance has been raised from 5*s.* to 7*s.* 6*d.* in first pregnancies, but in spite of this the number of insurances has increased. During 1930, 3079 midwives' cases insured and to them a doctor was summoned in 40 per cent. at a net cost to the council of 5*s.* 2*d.*

per case; whilst there were 2336 uninsured midwives' cases, to which the doctor was called on 833 occasions at a net cost to the council of 5*s.* 8*d.* The changes in the reasons for summoning medical aid, says Dr. Cronk, show that more attention is being paid by midwives to the necessity for calling in the doctor for complications which really matter. In the 19 public assistance institutions for which the county council is responsible, 47 beds are allocated for maternity cases, but only 102 births took place in these institutions during the year. The council's health visitors took over infant life protection work on April 1st. It was found necessary to withdraw approval from four foster-mothers formerly supervised by the guardians and from two foster-mothers notified after April 1st. Of 14 applications to receive foster-children two had to be refused as unsuitable.

The fifth county clean milk competition attracted a largely increased number of competitors. A new system has been introduced by which those who have attained the required standard in previous competitions are excluded from competing but become eligible for a Register of Accredited Milk Producers. Of the number eligible, 34 decided to register and both surprise and routine samples will be taken of their milk to ensure that they continue to practise what they have learned in the competitions. There is no routine inspection of the herds, and for checking the sale of tuberculous milk reliance is placed on notification by the owner, on outside complaints of tuberculous milk, on reports of tuberculous carcasses from the county slaughter-houses, and on the biological examination of 800 samples of milk supplied by the district councils. These methods resulted in 43 cows being dealt with under the Order.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 22ND, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 21 (last week, 19); scarlet fever, 1200: diphtheria, 652; enteric fever, 52; pneumonia, 393; puerperal fever, 39; puerperal pyrexia, 136; cerebrospinal fever, 20; acute poliomyelitis, 8; acute polio-encephalitis, 2; encephalitis lethargica, 10; dysentery, 5; ophthalmia neonatorum, 110. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 25th-26th was as follows: Small-pox, 27 under treatment (last week 35 under treatment, 2 under observation); scarlet fever, 1087; diphtheria, 1368; enteric fever, 18; measles, 134; whooping-cough, 362; puerperal fever, 22 (plus 14 babies); encephalitis lethargica, 211; poliomyelitis, 7; "other diseases," 106. At St. Margaret's Hospital there were 12 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (1) from enteric fever, 13 (0) from measles, 3 (1) from scarlet fever, 11 (3) from whooping-cough, 18 (0) from diphtheria, 37 (6) from diarrhœa and enteritis under two years, and 17 (1) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London occurred, two at Portsmouth and one at Nottingham. Three deaths from measles were reported from Leeds, two from Bradford. Hull reported four deaths from diphtheria. Diarrhœa was credited with eight deaths at Liverpool, four at Birmingham, and three at Newcastle-on-Tyne.

The number of stillbirths notified during the week was 315 (corresponding to a rate of 46 per 1000 births), including 52 in London.

ENLARGEMENT OF DUDLEY GUEST HOSPITAL. The nurses' home of this institution is to be enlarged immediately to accommodate 20 additional nurses. A further 28 beds will then be available, bringing the total to 135.

MEDICAL NEWS

Royal College of Physicians of Edinburgh.

On the occasion of the 250th anniversary of the College it has been decided to confer the honorary Fellowship on Sir David Bruce, Lord Dawson of Penn, Sir Archibald Garrod, Sir William Hale-White, Dr. Robert Hutchison, Sir Thomas Lewis, Sir Donald MacAlister, Sir Edward Sharpey-Schafer, Sir Charles Scott Sherrington, Dr. Charles Achard (Paris), Dr. Frederick Grant Banting (Toronto), Dr. A. A. Hijmans van den Bergh (Utrecht), Dr. Knud Faber (Copenhagen), Dr. George Richards Minot (Boston, U.S.A.), Dr. Friedrich von Müller (Munich), Dr. Hermann Sahli (Berne), Dr. William Sydney Thayer (Baltimore), and Dr. Julius Wagner-Jauregg (Vienna).

Medical Society of London.

The programme for the first half of the 159th session opens with the annual general meeting at 8 P.M. on Monday, Oct. 12th, after which at 8.30 P.M. Mr. Herbert Tilley will give his presidential address on the Laryngoscope in Medicine. Subjects for the fortnightly Monday evening discussions are as follows: Oct. 26th, Blood Transfusion, to be introduced by Prof. Alex. Fleming, Dr. H. L. Tidy, and Mr. Geoffrey Keynes. Nov. 23rd, Methods of Determining Liver Function and Their Value, to be introduced by Sir Humphry Rolleston and Prof. E. C. Dodds. Dec. 14th, X Rays in the Diagnosis of Thoracic Disease, to be introduced by Dr. P. J. Kerley, Dr. F. G. Chandler, and Mr. J. E. H. Roberts. All these discussions begin at 8.30 P.M. The clinical evening on Nov. 9th begins at 8 P.M.

Epsom College.

A vacancy has arisen for a Salomons entrance scholarship of £50 a year. Candidates must be sons of legally qualified members of the medical profession either living or deceased, and must have been over 11 and under 14 years of age on Jan. 1st last. They must show an adequate standard of education for their age, and their financial condition must be such as to make it impossible to obtain an education at the College without the help of the scholarship. Applications, in proper form, must reach the Secretary at 40 Bedford-square, London, W.C.1, by the morning of Sept. 30th.

Instruction for D.P.H.

A three months' course of lectures and demonstrations on clinical practice and in hospital administration will be given at the North-Western Hospital, Lawn-road, Hampstead, N.W.3, by Dr. Alexander Joe, the medical superintendent, on Mondays and Wednesdays at 3.30 P.M. and alternate Saturdays at 11 A.M., beginning on Wednesday, Sept. 30th. Application should be made to the Medical Officer of Health, London County Council, Public Health Department (Special Hospitals), Victoria Embankment, E.C.4.

Middlesex Hospital Medical School.

The ninety-seventh winter session will open on Thursday, Oct. 1st, at 3 P.M., in the Queen's Hall, Langham-place, London, W., when Prof. James McIntosh will deliver the introductory address and Sir John Bland-Sutton will distribute prizes gained during the previous year. At 7.30 P.M. on the same day the annual dinner will be held at the Savoy Hotel.

National Smoke Abatement Society.

The third annual conference of this society will meet at Liverpool from Sept. 18th to 20th, under the presidency of Dr. H. A. Des Voeux. Among the speakers will be Dr. J. Johnstone Jervis and Dr. James Bennett.

Fellowship of Medicine and Post-Graduate Medical Association.

There will be six special courses in September at the following institutions:—(1) Hospital for Consumption and Diseases of the Chest, Brompton, from Sept. 7th to 12th, all day. (2) Bethlem Royal Hospital, Monks Orchard, Eden Park, Beckenham, from Sept. 8th to Oct. 3rd, on Tuesdays and Saturdays at 11 A.M.; lecture-demonstrations in psychological medicine. (3) Infants Hospital, Vincent-square, from Sept. 14th to 26th, from 2 P.M. daily, with special visits in addition; course in diseases of infants. (4) Central London Ophthalmic Hospital, Judd-street, from Sept. 15th to Oct. 8th, each afternoon; lecture-demonstrations in ophthalmology. (5) Westminster Hospital, from Sept. 14th to 26th, all day; course in general medicine and surgery, for men only. (6) Metropolitan Hospital, Kingsland-road, from Sept. 28th to Oct. 10th, all day; course in general medicine and surgery. Copies of all syllabuses may be had from the Fellowship at 1, Wimpole-street, London, W. 1.

towns the burgh prosecutor can investigate fire outbreaks if requested by the town council or on special report by the firemaster that wilful fire-raising is suspected. As matters thus stand, the Royal Commission's recommendations are an obstacle to the extension of the City of London practice. Indeed the ancient usefulness of the coroner as an investigator of crime is latterly somewhat belittled. Section 20 of the Coroners (Amendment) Act of 1926, which put the coroner out of action when once the examining justices have taken in hand proceedings in cases of suspected homicide, was a serious break with the past.

BRITISH DERMATOLOGY.

To the "Annals of Medical History" (Vol. III., New Series, July, 1931), Dr. Haldin-Davis contributes an article of real historic interest setting out the foundations of British dermatology, from which we learn how comparatively modern is anything like rational treatment of skin diseases. From the very dawn of medicine affections of the skin must have received attention from doctors, for the sufferers from skin diseases are more urgent than any class of patients in their demands for relief, while it is a lamentable fact that a substantial proportion of them can only be offered remedial measures of a partial or temporary character. But there is hopefulness in the fact that with the general development of pathology more and more dermatological defaults, following upon the discovery of their origin, are yielding to intelligent therapeutics. Dr. Haldin-Davis attributes the progress of the last century mainly to the publication of Robert Willan's treatise in 1808. This was an attempt at the rational classification of skin diseases based upon characteristic lesions, and the author completed half of the projected work during his life-time. His pupil, Thomas Bateman, completed the treatise which was published under the heading "A Practical Synopsis of Cutaneous Diseases, according to the Arrangement of Dr. Willan." The basis thus introduced into dermatological classification has largely remained; where possible the scientific procedure of classifying by ætiology has replaced Willan's classification by appearances; but, as Dr. Haldin-Davis points out, our knowledge of the ætiology of skin diseases is lamentably deficient at the present day, except in the case of a few infective agencies, compelling us largely to classify skin diseases according to their appearances. Reading this article it becomes clear that Willan was a very remarkable man, for without the microscopic aid by which so many advances in this field of medicine have been made, he devised a system of classification 130 years ago which to-day is the main medium for intelligent converse between experts.

BLOOD PRESSURE IN THE CAPILLARIES.

RESEARCH which produces important results is of obvious value, but just as useful is the work which repeats research in order to confirm or disprove it. This checking of results will often prevent a whole crop of errors.

For a long time attempts have been made to measure the pressure in the capillaries. Many different methods have been applied, but so far no satisfactory solution of the problem has been found. Recently A. Sokolowski and M. Kubiczek [1] have undertaken investigations into the method designed by Kylin—a method of compression, which has hitherto been accepted as giving the most accurate data. They approached the problem from two aspects, considering first the technical difficulties arising from imperfections in the apparatus, and secondly, the results as interpreted in the light of the anatomy and histology of the part investigated. The imperfections in the apparatus, they found, made comparative study impossible and by certain modifications they tried to overcome them. Then they succeeded in making several interesting observations. For example, they noted that after the initial compression the capillary loops continued to contract despite a rapid diminution in the pressure. This suggested an active contraction on the part of the vessels as a result of irritation of the vasomotor nerve-endings in the vessel walls; consequently, any results obtain with this apparatus would be influenced in great part by the vasomotor nerves. Again, when an attempt was made to get repeated readings for comparative study—as, for example, when testing the effects of certain drugs—it was found that after each compression a strong vascular hyperæmia ensued, necessitating a pause of four to six minutes between each reading.

The second half of the work consisted of a careful examination of the anatomy and minute histology of the part which had been investigated—namely, the skin just behind the nail bed. Sections of various thicknesses were taken and stained by several methods. Correlating the results, they came to the conclusion that readings obtained by Kylin's method of compression, and, in fact, all compression methods, did not give the pressure in the capillaries, but gave actually the pressure in the afferent arterioles; in the area under examination the arteriole was the one described by and named after Spalteholz. Again, the results were influenced by the thickness of the skin of the subject investigated, and by several other factors.

The main result from these investigations is to show the innumerable difficulties in the way of any attempt to measure capillary pressure, and the inaccuracies of an accepted method.

ANÆMIA IN PREMATURE BABIES.

As a further supplement to the work of Dr. Helen Mackay [1] comes the report of some investigations by Dr. G. Sanpaolesi,[2] of Florence, carried out in Prof. Czerny's clinic in Berlin. He examined the blood of twelve premature babies at approximately weekly intervals, beginning from two days to three months after birth. He enumerated the total red blood corpuscles present, estimated the amount of hæmoglobin, and calculated the water content by the indirect method of determining the total solids. All the babies were born normally, ten were one month premature and two were two months premature. In one case congenital heart disease was present and another suffered from a congenital syphilitic infection. Otherwise the children were normal and developed normally except for slight digestive troubles which were without influence on the weight curve. None of the children showed evidence of the so-called exudative diathesis, held by some authorities to be the cause of the hydræmia from which they all appeared to suffer in the third month of life. In the first four weeks Sanpaolesi found normal values for total solids and water content of the blood but in the second month began a decrease in the solids and increase in the water content, associated with a parallel decrease in the number of red blood corpuscles and amount of hæmoglobin present. This was not accompanied by any alteration in the weight curves and in the child with congenital syphilis the decrease in total solids was more marked than in the normal babies, while the patient with congenital heart disease had only a minimum decrease. In two cases where vegetable additions to the diet were early introduced the decrease in total solids was very slight and there was a correspondingly quick recovery after the third month, although no influence of the diet on the total red cell count and hæmoglobin content could be detected. Sanpaolesi thinks that iron deficiency is not of great importance in the anæmia of the premature baby which seems to be due rather to a disturbance of the water-regulating mechanism of the body. Further observations on the total blood volume are necessary to settle this point and they present great practical difficulty. For the moment he merely draws the conclusion that there is certainly a dilution of the blood in the third month of life in premature babies and that this plays a part in producing what may be called the physiological anæmia of prematurity.

ADDRESSES AND ORIGINAL ARTICLES

PRECANCEROUS LESIONS OF THE ALIMENTARY TRACT.*

By Matthew J. Stewart, M.B. Glasg.,
F.R.C.P. Lond.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LEEDS.

LECTURE I.

In choosing as the subject of these lectures the precancerous lesions of the alimentary tract I had in mind two main considerations, one that it includes within its scope a number of pathological states for the study of which I could reasonably claim to have had exceptional opportunities; the other that it deals with matters of prime importance in medicine. The field is a big one, and I propose to concentrate on those aspects with which I am personally more familiar, and to make but passing reference to others of which I have had little or no experience. Of the importance of the subject it is hardly necessary to speak: the Registrar-General's statistical review for the year 1929 is sufficient demonstration. In that year there were 56,896 deaths from cancer in England and Wales, of which at least 60 per cent. in men and 42 per cent. in women were referable to the alimentary tract.

At the present time it is probably true to say that the most hopeful side of cancer research is that concerned with the demonstration of local causative factors, and the recognition and prevention of precancerous lesions of one kind or another. Unfortunately it is to the more superficial forms of malignant disease, a very small fraction of the whole, that this principally applies; precancerous lesions of the alimentary tract are by no means so well established, nor are there the same opportunities for prophylaxis.

The following is a rough attempt at classifying the chief precancerous lesions (or alleged precancerous lesions) of the various portions of the alimentary tract, and indicates also the order in which I propose to deal with them.

(a) Chronic inflammatory lesions: (1) leucoplakia; (2) lesions due to burns and chemical caustics; (3) cirrhosis of the liver; (4) hæmochromatosis; (5) cholelithiasis and cholecystitis; (6) chronic gastric ulcer; (7) chronic gastritis; (8) chronic duodenal ulcer; (9) diverticulitis.

(b) Simple tumours as precursors of cancer.

(c) Lesions due to animal parasites.

Leucoplakia.

The squamous epithelial lining of the mouth, pharynx and œsophagus, vulva, vagina and vaginal portion of the cervix, and part of the larynx, differs from the ordinary surface epithelium of the body in that it fails to form a definite stratum corneum, the effete surface cells being removed at an earlier stage of their development. In the so-called transitional epithelium of the urinary tract not only is there no keratinous layer, but even the stratum granulosum and stratum lucidum are lacking. In certain conditions of chronic irritation all this is changed, and patches of fully developed, highly keratinous epithelium make their appearance in the situations mentioned. The affected areas are white and opaque, stiff and unyielding, and in consequence liable to become cracked, fissured, and ulcerated. In leucoplakia vulvæ a special feature is the formation in the more advanced stages of a broad hyaline zone of dense collagenous deposit in the immediately subepithelial layer, accompanied by thinning and atrophy of the epithelium, complete or almost complete disappearance of the papillæ, and flattening out of the labia minora. In the tongue there is also an underlying chronic inflammatory lesion of the subepithelial layer which goes on to cicatricial fibrosis, but the broad, semitranslucent collagenous zone is not formed.

The distribution of leucoplakia is irregular and often asymmetrical. In the buccal cavity, much the commonest site, it affects chiefly the tongue, especially the anterior half of the dorsum and the margins, the commissures and cheeks, occasionally the lips, soft palate, and gums. The frequency of involvement of these sites in a series of 40 cases was found by Fox (1925) to be as follows: tongue, 28; commissures, 26; cheeks, 21; lips, 9; soft palate, 2; gums, 0. In the œsophagus it is seen first and chiefly in the lowest two or three inches, but may be widespread throughout the tube. The vulval lesion, not very uncommon, affects mainly the labia minora, but may extend on to the labia majora, perineum and thighs, and even encircle the anus. In the urinary tract, a much less frequent site, the bladder is the organ chiefly affected, the renal pelvis less than half as often, and the ureter and urethra only rarely. The combined figures of Hennessey (1927)—80 cases collected from the literature—and Kretschmer (1928)—13 new cases—are as follows: bladder, 49; bladder and ureter, 2; renal pelvis, 26; pelvis and ureter, 6; bladder, pelvis, and ureter, 3; ureter, 1; urethra, 3; not stated, 3; total, 93. Leucoplakia of the portio vaginalis cervicis is generally regarded as a rare disease, although Hinselmann, in a series of papers (*Cancer Review*, 1929, iv., 305) expresses the view that it is of frequent occurrence if only it is looked for.

ÆTIOLOGY.

This is different for different sites. In the mouth the chief cause is syphilis. Lane-Claypon (1930) found that in a collected series of 649 cases where the necessary information was available, 427, or 65·8 per cent., were definitely syphilitic. The lesion is a late one and is not amenable to antisyphilitic treatment. In the remaining cases, roughly one-third, other causes are at work, some of which are also additional factors in the syphilitic group, especially heavy smoking and more or less heavy drinking. Leloir (quoted by Lane-Claypon) gives details of the habits of 35 patients whom he investigated: 33 were heavy smokers and 27 more or less heavy drinkers. In this connexion attention is drawn to the extraordinarily low incidence of leucoplakia linguæ in women, only 3·5 per cent. of 848 cases collected by Cumston (1923) and 4·2 per cent. of 286 more accurately investigated cases collected by Lane-Claypon. It is particularly with reference to the tongue that a preponderatingly syphilitic ætiology is assigned. In leucoplakia of the lip there is little or no evidence that syphilis plays any part. Brofeldt (1927) investigated 25 cases of leucoplakia and 26 of cancer of the lips seen by him at Helsingfors in the period 1902–26. In none was there a positive Wassermann reaction or other evidence of syphilitic infection, and less than half were smokers.

Leucoplakia vulvæ is not a syphilitic affection; all observers are agreed on this point. It is probably related in most cases to cessation of the ovarian function, the average age at onset being 49 years (Taussig, 1929). In patients where the disease originates before the menopause there is usually a menstrual abnormality. Berkeley and Bonney suggest that coitus is an *important factor*. The *ætiology* of leucoplakia of the portio vaginalis cervicis is even more obscure, although here again syphilis is discounted by most observers. According to Hinselmann (1928) most cases are due to "external irritative influences."

---

* The Croonian Lectures delivered before the Royal College of Physicians of London on June 4th, 9th, and 11th, 1931.

In the urinary tract chronic inflammatory and obstructive lesions are usually present. Thus Hennessey (1927) found the following associated conditions in 80 collected cases: cystitis, 58; obstructive lesions, 31; pyelonephritis, 25; calculus, 20; tuberculosis, 6; carcinoma, 4. In this series the bladder was affected with leucoplakia 47 times, the pelvis 32 times, and the ureter 11 times. In another (overlapping) series of 77 cases collected by Redewill (1929) the following lesions were present: chronic pyonephrosis, 25; hydronephrosis, 25; stone in the kidney, 10; stone in the ureter, 2; stone in the bladder 3; stone in the opposite kidney and ureter, 1; tuberculosis, 7; carcinoma, 4. Redewill makes the interesting suggestion that vitamin deficiency (especially deficiency of vitamin A) is an important ætiological factor (cf. xerophthalmia, which is a closely similar change in the conjunctival epithelium resulting from vitamin A starvation), and claims to have cured two cases by increasing the vitamin content of the diet and administering parathyroid.

RELATION TO CARCINOMA.

This has been so recently discussed by Lane-Claypon for carcinoma of the tongue that I content myself here with a brief reference to some of her main conclusions. She finds that up to the present time no data are available which enable the frequency of the supervention of cancer of the tongue in syphilitic subjects (or in those with leucoplakia, syphilitic or otherwise) to be ascertained. Yet there is no doubt that the association exists. The sex-incidence is similar; both show a remarkable preponderance in males (leucoplakia 95·8 per cent., carcinoma 90·2 per cent.). In a collected series of 447 cases of leucoplakia, 130 (29·1 per cent.) had already become cancerous, and in view of the youth of some of the patients there was still abundant time for others to develop malignancy. Perrin's figures, quoted by Lane-Claypon, are of interest. He analysed 102 cases of leucoplakia buccalis as follows:—

		With cancer.
Syphilitic (64).		
Leucoplakia of cheek and lips ..	11	0
,, ,, tongue	53	10
Non-syphilitic (38).		
Leucoplakia of cheek and lips ..	15	0
,, ,, tongue	23	9

He concludes that syphilis does not predispose to leucoplakia of the lips or cheeks but does so for the tongue, and that syphilis in combination with tobacco is the commonest cause of cancer of the tongue.

The evidence for an association between leucoplakia and carcinoma of the œsophagus is extremely slight. I have only been able to find casual references to the subject in the literature, and my own experience in the post-mortem room has been of a negative kind.

Leucoplakia vulvæ is an accepted precancerous lesion, although here again it is impossible to get reliable figures. Berkeley and Bonney (1910), in reporting their personal experience of 58 cases of carcinoma vulvæ, state that they have not yet seen a case in which leucoplakia did not coexist. They report at the same time 19 cases of leucoplakia without malignancy. Taussig (1929), in a series of 76 cases of cancer of the vulva, noted leucoplakia in 39. In the same period he saw 40 cases of leucoplakic vulvitis without malignancy. Carcinoma vulvæ is more frequently multiple in origin than any of the commoner forms of malignant disease; 4 of Berkeley and Bonney's 58 cases were of this class, and I have recently seen a case of widespread leucoplakia of vulva, perineum, and anus in which early but unmistakable carcinoma was present at two widely separate points, one on a labium minus, the other on the anus.

The relationship between leucoplakia and cancer of the cervix is less securely founded. Hinselmann (vide supra), the chief exponent of leucoplakia cervicis as a pathological entity, believes that conservatively treated cases become carcinomatous in a few years, that in fact such leucoplakias represent the early non-invasive stage of carcinoma and not merely a precancerous condition. Cases supporting this view have been published by Rogge (1929) and Landesmann and Einoch (1929), but the total available evidence is scanty and unconvincing.

In the urinary tract also the evidence for an association between leucoplakia and cancer is inadequate. In recent years several American authors have analysed the literature, but the total number of cases is small. In 80 cases collected by Hennessey (1927) there were 4 cases of carcinoma, all squamous, an incidence of 5 per cent. Redewill (1929), in a partially overlapping series of 77 cases, had 4 cases of carcinoma, 3 in the bladder and 1 in the pelvis.

It may be concluded, therefore, that leucoplakia linguæ and leucoplakia vulvæ are definitely precancerous lesions, the former usually though not invariably due to syphilis, with heavy smoking and drinking as auxiliary factors. Leucoplakia vulvæ is not syphilitic. So far as the œsophagus, larynx, cervix uteri, and urinary tract are concerned, an association between leucoplakia and cancer is still unproved.

Lesions Due to Burns and Caustics.

Cancer of the lip.—One of the remarkable features of this disease is the great difference in its incidence in the two sexes. In a collected series of 4839 cases (Lane-Claypon, 1930) the proportion in males was 93·5 per cent. Another important point is the comparative rarity of cancer of the upper lip, 5·8 per cent. of a series of 3763 cases. Yet nearly one-quarter of all cases in women (50 out of 210) are in the upper lip, leaving for men only 88 out of 2466 cases (3·6 per cent.) so situated. Lane-Claypon discusses the ætiology at length, and concludes that there is no statistical evidence to support the view that smoking *as such* is causally related. There is reason to believe, however, that the unglazed clay pipe, especially when broken off short, may cause such chronic burning of the lower lip (with which it is in much more continuous contact) as to lead to cancer. Brewer (1923) states that in the district of Columbia only 8·04 per 100,000 white women over the age of 70 die from cancer of the lip, whereas the corresponding figure for negresses, a large proportion of whom smoke clay pipes, is 30·1 per 100,000.

The importance of prolonged exposure in the open air is stressed by Young and Russell (1926), who find that in agricultural labourers, merchant seamen, dock-labourers, and outdoor railwaymen cancer of the lip is 200 to 300 per cent. in excess of what might be expected. Masons, general labourers, farmers, graziers, and paviours come next with 60 to 100 per cent. excess. These open-air workers have in common unrestricted opportunities for smoking, and in the past, at least, clay pipes were much in favour amongst them. They mention the fact that coal-miners working below ground, where smoking is forbidden, contrast with those working above ground in not suffering from excess of lip cancer. Young and Russell suggest that tobacco smoke may contain distillation products which act in a similar way to coal-tar and soot. There is no evidence to incriminate syphilis, and little or nothing to suggest an association with leucoplakia.

Betel-nut cancer of the cheek.—This also is fully discussed by Lane-Claypon (1930). It is clear that in certain districts of India and the East where betel-chewing is a widespread habit, the incidence of carcinoma of the cheek is extraordinarily high. Thus Fells in Southern India found that out of 377 cases of epithelial cancer seen by him, 91·5 per cent. were connected with the buccal cavity, 83·2 per cent. originating in the cheek, 9·3 per cent. in the tongue, and 7·5 per cent. in the lip. The betel "quid" is ordinarily carried inside the cheek, and it is on the buccal mucosa at this point, just opposite the molars and pre-molars, that the changes occur which ultimately lead to malignancy. Inflammatory thickening and roughening of the mucosa, leucoplakia, and epithelial denudation occur, and are followed by progressive ulceration.

There is, however, great variation in the cancer incidence in different betel-chewing populations. Thus Snijders and Straub (1923) found no evidence of its frequent occurrence in Dutch East Indies, where betel-chewing is common: Maxwell (1924) and Wells (quoted by Lane-Claypon) report similar experiences from Formosa and Guam. Snijders and Straub, from a review of the literature, give the following figures: Travancore, 652 buccal cancers amongst 1700 in all sites (38 per cent.); Madras, 411 in 976 (42·1 per cent.); Ceylon, 422 in 1325 (32 per cent.). Degorce in Tonkin saw only a few cases, while Montel in Saigon, in a similar (Indo-Chinese) population, saw many oral cancers. It is suggested that the difference may be due to the composition of the "quid," which varies in different countries and in different districts. Sabesan (1928) believes that in Madras the chewing of tobacco in addition to betel-nut is responsible for the high incidence, while for Singhalese, van Dort (1923) blames the short strong cigar much used by natives of Ceylon.

Betel-nut cancer, then, affords an excellent example of the importance of local factors in cancer causation, ranking in this respect with "kangri" cancer, tar and soot cancer, and mule-spinners' and X ray cancer.

Cirrhosis of the Liver.

INCIDENCE OF PRIMARY CARCINOMA.

Primary carcinoma of the liver is a rare disease in the white-skinned races. In Leeds, in 12,800 autopsies† during the period 1910–31, there were 14 certain cases, or 0·11 per cent. Even if 7 doubtful cases be added to this list the incidence is still only 0·16 per cent. If, however, only cases of 30 years of age and over are included, these figures become increased to 0·16 and 0·25 per cent. respectively.

Very similar figures have been recorded by other observers, both here and in America. It would appear, however, from numerous published observations that there is a much higher incidence among many non-white-skinned races (Table I.).

TABLE I.—*Racial Incidence of Primary Carcinoma of Liver.*

—	Total autopsies.	Cases of primary carcinoma of liver.	Percentage incidence.
English (Hale-White, Stewart)	31,300	39	0·12
Hungarian (Goldzieher and v. Bokay)	6,000	18	0·3
American and Canadian* ..	17,736	26	0·146
Chinese and Javanese† ..	1,075	25	2·3
South African Natives (Strachan)	1,100	22	2·0

* Clawson and Cabot, Fried, v. Glahn and Lamb, Counseller and McIndoe, Ophüls, and Strong and Pitts.

† Snijders and Straub, Ophüls, Strong and Pitts.

These figures show a statistically significant difference not only between English and American whites on the one hand and the Chinese-Javanese group on the other (2·21±0·46 per cent., and 2·18±0·46 per cent. respectively), but also between the two former groups and the Hungarians (0·18±0·07 per cent., and 0·154±0·076 per cent.).

Indirect evidence of racial variation is also available. Harvey Pirie (1921–22) found 36 primary cancers of the liver amongst 91 carcinomata in South African natives, whilst Snijders and Straub (1923) in the Dutch East Indies had 83 amongst 447 tumours examined (18·6 per cent.). Almost the whole of these liver cancers came from Javanese and Chinese patients, amongst whom they represented 57 per cent. and 32 per cent. respectively of all tumours examined. Snijders and Straub have also collected from the literature of the Far East much additional information on this point. Table II. is compiled from their data.

TABLE II.—*Incidence of Primary Carcinoma of the Liver in the Far East.*

Race.	Autopsies.	Cases of primary carcinoma of liver.	Incidence.
Japanese	12,212	125	1·02
Chinese	1,057	13	1·23
Javanese	658	8	1·22

Various explanations of this heightened racial incidence have been forthcoming. In the Far East and in South Africa the hepatic cirrhosis of schistosomiasis has been regarded as a possible factor, and in China, infestation by another fluke, *Clonorchis sinensis*. These are discussed in Lecture III. Snijders and Straub suggest that the "repeated and chronic affections of the sources of the portal vein" so frequently present in the native inhabitants of tropical countries "may play a part in the ætiology of cirrhosis and cancer of the liver." van Dort (1923) makes the suggestion that the varied incidence of primary cancer of the liver in different countries has a racial basis. He points out that in Europe there is a higher incidence among Magyar and Mongolian races than among those of Aryan stock; that Madras, peopled by Dravidians, shows a high rate, Calcutta and Colombo, inhabited by Aryans, a low, while the

---

† It is a serious objection to much of the published statistical material available that the age-distribution of the hospital populations from which it has been obtained is not clearly indicated. The figures for the Leeds General Infirmary during the period under review are as follows:—

Age- and Sex-Distribution of 12,800 Consecutive Autopsies at the Leeds General Infirmary, Jan. 1st, 1910, to May 5th, 1931.

Decade.	Males.	Females.	Totals.	
0– 9.. ..	1526	1079	2605	4887 under 30.
10–19.. ..	725	420	1145	
20–29.. ..	656	481	1137	
30–39.. ..	868	548	1416	7913 30 and over.

incidence is again high amongst negroes, Chinese, and Javanese.

VARIETIES OF CARCINOMA.

There are two main varieties of hepatic carcinoma, the liver-cell type or hepatoma, and the bile-duct type or cholangioma (Yamagiwa, 1911). The older classification of Eggel (1901) into massive, nodular, and diffuse has a certain descriptive value, while the separation of a special type of "cancer avec cirrhose" (Hanot and Gilbert, 1888), has much to be said for it, especially on clinical grounds. Both histogenetic types may arise in cirrhotic livers, and may assume one or other of the three anatomical forms.

The main distinguishing features of the two types are briefly these (Winternitz, 1916).

(*a*) Liver-cell cancer has a trabecular structure, the cell columns being solid as a rule, although lumina may be present and may contain bile. Stroma is scanty in the extreme, practically only a capillary core; and the tumours are, in consequence, very soft. They are very liable to undergo central necrosis and hæmorrhage. The scantiness and looseness of the stroma is occasionally responsible for a remarkable pseudo-papillomatous formation (Fried, 1924; Keith and McNair, 1930). These apparent intracystic papillæ, which are really intravascular, are simply solid or luminated epithelial columns each enclosed in a delicate sheath of endothelium. The cellular structure is polymorphic, but nearly always one can find groups of cells with granular, well-stained cytoplasm, closely resembling the normal parenchyma cells of the liver. The formation of enormous giant cells, both mono- and multinuclear, is a not uncommon feature (van Heukelom, 1894; Muir, 1908), and plugs of inspissated bile may even be present within their cytoplasm (Rowen and Mallory, 1925).

(*b*) The bile-duct carcinomata are tubulo-adenomatous, have a more or less abundant, densely fibrous stroma, and are composed of cubical or subcolumnar cells with clear cytoplasm resembling the lining epithelium of the bile canaliculi. Atypical varieties of both tumours occur, and tumours apparently of mixed type, some being "so far removed from their usual morphology that some doubt must always remain regarding their true origin" (Ewing, 1928). Bile may be present in either variety, in the one case the product of the functional activity of the tumour cells, in the other a derivative of the surrounding healthy liver entering secondarily from without. Many hepatomas are yellow or orange in colour as a result of their high bile-pigment content, and in contradistinction to cholangiomas bile may be formed in the secondary deposits in the lungs (Cloin, 1901; Ménétrier, 1908; Ribbert, 1909; Parkes Weber, 1910; Fried, 1924).

Liver-cell carcinoma is much the commoner. In Eggel's collected series the ratio was 7 to 1, in Yamagiwa's roughly 2 to 1, and in Goldzieher's 3·5 to 1. In my series there were 9 hepatomas and 4 cholangiomas. Table III. shows that there is little or no difference in the comparative frequency in the white-skinned and coloured races.

RELATION OF CIRRHOSIS TO CARCINOMA.

That cirrhosis of the liver is a precancerous condition is now generally accepted. Most of the statistical evidence in support of this belief comes from figures showing a high incidence of cirrhosis in cases of primary cancer. Statistics showing the comparative frequency of primary carcinoma in cirrhotic and non-cirrhotic livers respectively are remarkably few. My own figures have been worked out on this basis.

Multilobular or portal cirrhosis is a disease of middle and later life. After excluding from my series all cases of Banti type, and all cases of post-necrotic (post-atrophic) fibrosis, whether accompanied by multiple nodular hyperplasia or no, there remain 269 patients with cirrhosis of whom five only were under the age of 30. All the cases of primary carcinoma but one were also over 30, and I have therefore made a correction for age by including only those who were 30 years of age or over.

TABLE IV.

Incidence of primary cancer of the liver in 7913 patients 30 years of age and over (from a consecutive series of 12,800 autopsies at all ages at the Leeds General Infirmary).

		Per cent.
Cases without cirrhosis	7619	—
Cases of primary cancer therein ..	4	0·052
(With 7 doubtful cancer cases included)	11	0·144
Cases with cirrhosis	264	—
Cases of primary cancer therein ..	9	3·41

Table IV. shows, therefore, an enormous preponderance in favour of the cirrhotic group.

Two incidence-rates for the non-cirrhotic cases are given, one including only those primary carcinomas which satisfy the most stringent requirements, the other with the doubtful cases added. With the former the cancer incidence in cirrhosis is 66 times, with the latter 24 times greater than in the non-cirrhotic group. Even for the latter the difference is statistically significant (3·27 ± 1·12 per cent.).

Similar findings were obtained by Ophüls (1926). In 128 cases of cirrhosis of the liver over the age of 30 there were 8 with primary carcinoma (6·2 per cent.), while in the corresponding group without cirrhosis there were 3 cases of cancer in 2111 (0·14 per cent.), a ratio of 44 : 1.

Blumenau (1920–21), in 12,761 autopsies, encountered 198 cases of cirrhosis of all grades, of which 7 were associated with primary carcinoma (3·5 per cent.).

These three series include all grades of cirrhosis recognisable by the naked eye, whereas carcinoma, when it occurs in a cirrhotic liver, does so as a rule late in the disease. In my series, if the slighter cases of cirrhosis are excluded, there remain, over the age of 30, 124 cases of cirrhosis with 9 cases of cancer, an incidence of 7·3 per cent.

Approaching this problem from the other direction, we find in the literature abundant evidence in support of the contention that a large majority of carcinomas of the liver, especially those of liver-cell type, arise in cirrhotic organs (Table V.).

TABLE V.—*Frequency of Cirrhosis in Cases of Primary Carcinoma of the Liver.**

—	Cases.	With cirrhosis.
Liver-cell carcinoma ..	246	219 (89·0 per cent.)
Bile-duct ,, ..	49	25 (51·0 ,,)

* Collected from the series of Eggel, Goldzieher and v. Bokay, Karsner, Yamagiwa, Winternitz, Harvey Pirie, Snijders and Straub, Fried, v. Glahn and Lamb, Counseller and McIndoe, Strong and Pitts, and Stewart.

The incidence of cirrhosis is thus significantly higher in liver-cell than in bile-duct cancer (difference 38·00 ± 7·41 per cent.).

Carcinoma occurring in a cirrhotic liver is the end-stage of a well-recognised series of pathological changes. Both portal cirrhosis and acute cytolytic necrosis are due to the action of toxic substances, some of which are either definitely known or strongly suspected—e.g., trinitrotoluene in the one case, and alcohol or some associated substance in the other. But there is a vast difference in the mode of action of the causative agents in the two diseases. Cytolytic necrosis occurs rapidly, and the final result depends partly on the severity of the intoxication, partly on the extent of the destructive lesion. If necrosis is very extensive death ensues within a few days, and the condition is known as acute yellow atrophy. If a certain, perhaps even a small, amount of liver tissue withstands the toxic onslaught, the patient may survive for some weeks or months, and at autopsy the destroyed liver tissue is found to have become replaced by cellular fibroblastic tissue, the surviving islets of parenchyma being in a state of more or less active proliferation. This is the stage of subacute atrophy or necrosis. Finally there are the cases which survive for many months or years, and in whom the regenerated liver tissue compensates more or less adequately for what has been destroyed. Such livers often present the appearance known as multiple nodular hyperplasia, with numerous rounded nodules of regenerated functioning liver tissue separated by broad tracts of post-necrotic fibrosis. In cytolytic necrosis all the damage to the liver is done at one blow. Once the destroyed tissue has become fibrosed and a certain degree of regenerative hyperplasia attained the lesion becomes static.

In cirrhosis, on the other hand, the toxic action is long continued, and the destructive effect, with its associated demand for compensatory hypertrophy, probably lasts many years. The lesion, in short, is a progressive one. I believe it is for this reason that the process does not always stop short at the stage of multiple nodular hyperplasia. From time to time cases are encountered in which actual liver-cell adenomata are formed, and this in turn may be followed by malignancy. Sabourin (1881, 1884) was the first to suggest that multiple nodular hyperplasia might be an intermediate stage between cirrhosis and cancer, a view since strongly supported by Orth (1887), Schmieden (1900), Muir (1908), Turnbull and Worthington (1908*a*), and others. I believe, however, that this applies only to the nodular hyperplasia of cirrhosis. I am unaware of any reported case of primary cancer arising in a liver the seat of post-necrotic fibrosis with multiple nodular hyperplasia. In none of 13 cases of post-necrotic fibrosis encountered in the post-mortem room at Leeds was there any evidence of new growth. In the patients who recover from cytolytic necrosis and in whom the regenerated liver is sufficient to maintain life, no further destruction of cells takes place (unless they go through a fresh attack, which is rare), and no further demand for compensatory hypertrophy. In cirrhosis there is "a progressive destruction of liver-cells, followed by a progressive compensatory hypertrophy and hyperplasia" (Muir, 1908), which in a not inconsiderable number of advanced cases "oversteps the normal, and takes on the autonomous character of a new growth."

An interesting controversy has ranged around the question of the unicentric or multicentric origin of primary liver-cell cancer. The chief supporters of the latter (and earlier) view are van Heukelom (1894), Löhlein (1907), Muir (1908), Goldzieher and v. Bokay (1911), and Yamagiwa (1911); of the former, Ribbert (1909, 1911), Karsner (1911), Winternitz (1916), and Counseller and McIndoe (1926). That adenomata of the liver are frequently multiple, especially in the cirrhotic organ, everyone will admit. So far as primary liver-cell cancer is concerned, I am strongly of the opinion that most, if not all, of the cases of apparently multicentric origin can be explained in other ways. Primary cancer, especially of the liver-cell type, readily invades the portal vein, which becomes occupied by a solid yellowish mass, partly thrombus, partly tumour tissue. The growth extends along the lumen in both directions from the point of entry, ultimately forming a tree-like cast of the affected portion of the portal system. It is these growth-distended vessels seen on section which give the appearance of a tumour of multicentric origin. Furthermore, when once the portal system has been invaded dissemination to other parts of the liver readily occurs (Willis, 1930). Invasion of the hepatic vein is less common, and in rare instances the inferior vena cava is permeated and obstructed by growth (Fabyan, 1907; von Glahn and Lamb, 1924; Rowen and Mallory, 1925; Counseller and McIndoe, 1926).

Bile-duct carcinoma, although it grossly invades both portal and hepatic veins less frequently than liver-cell cancer, is more liable to give rise to extrahepatic metastases. Table VI. is compiled from my own cases, and from those of Muir (1908), Turnbull and Worthington (1908*b*), Karsner (1911), Winternitz (1916), von Glahn and Lamb (1924), and Counseller and McIndoe (1926).

TABLE VI.—*Frequency of Vascular Permeation and Extrahepatic Metastasis in 44 Cases of Primary Carcinoma of the Liver.*

—	Cases.	Invasion of		Regional gland secondaries.	Pulmonary secondaries.	Bronch. gland secondaries.	Deposits elsewhere.
		Portal vein.	Hepatic vein.				
1. Hepatoma ..	33	28	4	4	6	0	0
2. Cholangioma	11	5	0	4	3	3	6

In all, there were 16 cases (9 out of 33 hepatomas and 7 out of 11 cholangiomas) with extrahepatic metastases (36·4 per cent.). In Eggel's series of 163 cases there were 66 with extrahepatic metastases (40·5 per cent.), including 23 cases of lung involvement —14 per cent., as compared with 20 per cent. in the above series.

It is scarcely necessary after this to discuss the various other hypotheses as to the relation of the cirrhosis and the cancer; that the two are independent, that they occur simultaneously in response to some common stimulus (Hanot and Gilbert, 1888), that the cancer is the cause of the cirrhosis. For the first and second no case has been made out. With regard to the third, it is true that liver-cell carcinoma in particular may stimulate the formation of a wall of fibrous tissue around it, but this is a strictly local development, and does not extend into the normal parenchyma of the rest of the organ.

CIRRHOSIS AND SARCOMA.

Sarcoma of the liver is an extremely rare disease. As in carcinoma there is a certain association with cirrhosis. Jaffé (1924) has collected and analysed the available data. He finds that of 48 cases of sarcoma 15, or 29·2 per cent., were accompanied by cirrhosis.

Hæmochromatosis.

Hæmochromatosis is a disease in which enormous quantities of the iron-containing pigment hæmosiderin are deposited in various organs of the body, but especially in the liver, which, whether as a result or as a cause of the siderosis, or independently, becomes the seat of multilobular (portal) cirrhosis of the usual type. The deposition of pigment is unassociated with other evidences of excessive hæmolysis, and belongs therefore to an entirely different category from the siderosis of Addisonian anæmia or hæmolytic jaundice. The free iron content of the liver may be as much as 6 or 7 per cent. of the dry weight, and the total iron content anything up to 30 g. or more instead of the normal 0·3 g. or less (Muir and Dunn, 1914–15).

There occurs also an enormous accumulation of hæmosiderin in the upper abdominal lymph glands, especially those of the cœliac group, where the iron content may be 14·69 per cent. of the dry weight (Anschütz, 1899). It is clear that the bulk of this pigment is transported thence from the liver, to some extent also from the pancreas. No such transportation to or accumulation of pigment in the cœliac glands occurs in the hæmolytic anæmias, probably because of the need for and the availability of the iron-containing fraction for further erythropoiesis.

After the liver, in pernicious anæmia the kidneys show the largest amount of pigment, and may even be the organs chiefly or solely affected. In hæmochromatosis renal siderosis is usually very slight. In Muir and Dunn's case the iron content was only 0·406 per cent., as compared with 6·43 per cent. in the liver and 2·49 per cent. in the pancreas. Apart from the liver and kidneys no appreciable degree of siderosis occurs in pernicious anæmia. In hæmochromatosis the pancreas ranks next to the liver and lymph glands as the chief site of iron deposition. It is unusual for the spleen to be much affected, but the heart-muscle, suprarenals, skin, thyroid, prostate, salivary glands, stomach, and choroid plexuses may all show considerable or even great pigmentation.

INCIDENCE.

In the collected series of 38,095 autopsies in five British hospitals shown in Table VII. there are 52 cases of hæmochromatosis (0·136 per cent.). Strachan (1929) found a much higher incidence both in South African natives (3·0 per cent.) and in the white inhabitants of that country (1·38 per cent.), but failed to discover any satisfactory explanation. In my series there were 264 cases of cirrhosis of the liver 30 years of age or over, and as all my 13 cases of hæmochromatosis showed cirrhosis and were over 30, the incidence of hæmochromatosis in this group is 4·9 per cent. Hæmochromatosis, however, is mainly a disease of males—there were no women in my series—and here the incidence rises to 7 per cent.

ÆTIOLOGY.

The ætiology of hæmochromatosis is very fully and adequately discussed by Rolleston and McNee (1929), and I shall only refer here to one or two salient points. It is a very obscure problem, and no definite conclusions can as yet be stated.

(1) There is general agreement that the siderosis is not dependent on increased hæmolysis. As already shown, the amount and distribution of the pigment differs widely in the two cases, and there is no evidence of excessive hæmolysis.

(2) There is a preponderance of opinion in favour of the view that in the liver the cirrhosis is antecedent to the siderosis, and in support of this the fact that chronic alcoholism is a frequent precursor of both diseases has been cited. This ætiological conception, however, fails to explain the widely generalised siderosis of hæmochromatosis, nor does it throw any light on the fibrosis of the pancreas which occurs in some cases.

(3) Mallory and others (Mallory, Parker, and Nye, 1920–21; Mallory, 1925, 1926) have advanced the view that the cause of the disease is chronic copper poisoning, and have adduced much clinical evidence in support of their contention. It is indeed a remarkable fact that Mallory should have had such an extraordinary run of cases since long-suffering Americans have taken to distilling their own "hooch" in copper-tubed stills, but there remains the difficulty of accounting for the vast quantities of iron present. Clearly in many of the cases the process of siderosis must have been in existence much longer than the supposed period of exposure to copper, dating from days when good corn and rye whisky was the favourite tipple of American inebriates. If, on the other hand, the source of the copper is the lining of pans used for jam-making and other culinary purposes, or the colour-preservatives added to canned vegetables, why is the disease limited to such an extraordinarily small fraction of the population, and in particular, why is there such an extreme preponderance in the male sex? Mallory's experimental results in support of the copper theory fail to carry conviction (Flinn and von Glahn, 1929; Polson, 1929). It may be mentioned that in Korea, where bronze and copper vessels are habitually used, R. G. Mills (1925) found no evidence either of hæmochromatosis or of an increased incidence of diabetes.

(4) There remains the hypothesis, which unfortunately does not carry us much further, that the essential factor is "a special affinity of the tissues and organs for iron" (Muir, 1921). The *cause* of this accumulation is unknown, although the *source* of the iron must obviously be the food. The total iron content of the body in advanced cases is so enormous that at the normal rate of intake (10 milligrammes of iron per day on an ordinary diet (Stockman, 1895, 1897)), it would require many years to accumulate, even if all the iron ingested were retained. It is even possible that the condition is lifelong, but as against that must be set the fact that the disease, even in its early stages, is hardly ever encountered before the age of 30. That there is a failure of elimination of iron may be assumed.

It is an equally attractive hypothesis that damage to parenchyma cells by surcharge with iron pigment is the cause of both hepatic and pancreatic sclerosis, perhaps also of a cortical adrenal lesion leading to genuine Addisonian pigmentation. Contrary to Rolleston and McNee, I find that siderosis of the cœliac lymph glands sets up a definite fibrosis of these structures, nor do I agree that the absence of hepatic fibrosis in the hæmolytic anæmias, where siderosis is relatively slight and probably intermittent, is an argument against this hypothesis. Siderosis of liver-cells in varying degree is present in many cases of ordinary multilobular cirrhosis, but there is no evidence of any close relation between this condition and hæmochromatosis.

RELATION TO CARCINOMA.

Hæmochromatosis, when recognisable as such in the post-mortem room, is invariably accompanied by some degree of hepatic cirrhosis, and might therefore be expected to have an association with primary carcinoma of the liver. My interest in this side of the problem has been stimulated by the fact that in the past 16 years I have encountered no fewer than three instances of this association in a series of 13 cases of hæmochromatosis seen in the post-mortem room at Leeds. In such a small series one naturally assumed that this was a mere error of random sampling, and in order to get a more truthful figure I have collected a number of series, published and unpublished. Through the kindness of Profs. Muir, Turnbull, and Kettle, and Dr. Newcomb, I have been supplied with the lists of cases of hæmochromatosis occurring at the Western Infirmary of Glasgow, the London Hospital, and St. Bartholomew's and St. Mary's Hospitals respectively during the last 15 or 20 years. In making a collection from the literature only *series* of cases have been included, not isolated examples, since it seemed probable that the latter would include an undue proportion of rarities such as the one under discussion. Table VII. gives the results of the inquiry.

TABLE VII.—*Incidence of Primary Carcinoma of the Liver in Hæmochromatosis.*

Grand total ..	—	151	15	9·93

*Those of Althausen and Kerr, Blanton and Healy, Bork, Letulle, Mills (E. S.), Ophüls, and Strachan.

The total figure (9·93 per cent.) is a somewhat higher incidence than is met with in cirrhosis generally —viz., 3·41 per cent. A fairer comparison, however, would be with cases of established cirrhosis after excluding the slighter grades. In my series there were 124 such cases, with 9 cases of cancer, an incidence of 7·3 per cent. As the difference between these rates (2·67 per cent.) is less than its standard error (3·37), it is not possible to attach any significance to the apparently higher rate in hæmochromatosis. The causative factor in both groups is the cirrhosis, the siderosis probably playing no direct part. In passing it may be mentioned that cases of primary carcinoma of the pancreas with hæmochromatosis have been reported by Critchlow (1929) and Strachan. It is unlikely that this association is other than accidental.

Primary carcinoma of the liver in hæmochromatosis is similar to the disease as it occurs in ordinary portal cirrhosis. For purposes of comparison I have collected in Table VIII. all the 14 reported cases which I have been able to find in the literature, adding thereto my own three. I know of seven other unreported cases, four in Great Britain (Muir, Turnbull, Dunn, and Polson), and three in South Africa (Strachan).

incapable of carrying on with his work without periods of rest. He had lost weight. In 1927 his condition was believed to be due to myocardial failure, but this opinion was negatived by the report of the cardiac specialist. Rest and tonics were prescribed. In October, 1928, he had some lower abdominal discomfort, and complained of constipation and of feeling the whole of the cæcum against the abdominal wall.

The cæcum and descending colon were thickened and easily palpable, but there was no tenderness. A barium X ray meal on March 21st, 1929, showed the following abnormalities:—(1) Hyper-activity of the duodenum. 6½ hours after ingestion: (2) cæcal pole very movable. Appendix partly but only slightly filled. 8½ hours after ingestion: (3) freely movable appendix not obvious either on film or on screen. 48 hours after ingestion: (4) cæcum contains some barium mixed with food. The radiologist further reports: (5) "Appendix did not fill like 99 per cent. of normal ones, but that is the only point against it."

The condition was believed to be due to visceroptosis and overwork. One month's rest in a nursing home with abdominal massage was prescribed, preceded by two weeks' holiday. The constipation was entirely relieved, but the "fatigue" continued unrelieved.

Six months later, the fatigue condition having become unutterably intolerable, and the patient totally unable to carry on with his work, appendicectomy was decided upon. At operation on Nov. 22nd, 1929, the cæcum was found adherent to the abdominal wall. There was a mass of adhesions round the appendix, which was twisted on itself, the two loops being adherent. The appendix was opaque and thickened, with congested vessels. Twelve months later the toxæmic symptoms had entirely disappeared, and the patient was very well.

GROUP IV.—MALAISE, LASSITUDE, AND ABDOMINAL SYMPTOMS.

CASE 16, a boy aged 16½ years, stated that from Christmas, 1929, to February, 1930, he had had discomfort in the epigastrium a quarter of an hour after meals, but no vomiting. On one occasion he had had acute pain round the umbilicus, lasting for five minutes. This had doubled him up, but had not been accompanied by vomiting. He had had constipation for 12 months.

Increased resistance was found in the upper two segments of the right rectus. A barium meal on Feb. 26th, 1930, showed the following abnormalities:—Excessive peristalsis, to-and-fro movement in the duodenum. 7 hours after ingestion: (1) appendix partly filled; ? kinked; no tenderness. 8½ hours after ingestion: (4) appendix slightly movable; no tenderness. The radiologist further reports: (3) "*Previous to giving the meal, a film of the abdomen* shows a large calcareous mesenteric gland."

Although in this case the diagnosis of "poisoning appendix" was made, the surgeon did not agree, and

Case	Age.	Shown by X rays: alterations from normal.		—	Main features at operation.	Age.	Case
		In upper abdominal tract.	In cæcal area.				
			Symptomless Pyrexia (Two Cases).				
1	38	—	Appendix not seen. Cæcum not movable. Tenderness.	C. gs.	Free fluid. Appendix injected, œdematous. Cæcum bound down by adhesions.	38	1
15	11	Excessive peristalsis.	Appendix not filling properly.	C. gs.	Multiple adhesions.	11	15
			Pyrexia and Vomiting (Three Cases).				
2	51	Gastric rate of emptying unduly rapid.	Fixed appendix. Cæcum tender. Concretions.	C. gs.	Appendix bound down by adhesions middle two-thirds. Fibrotic	51	2
11	6	No observations made.	Appendix never properly filled. Cæcum not movable. Tender.	C. gs.	Appendix bound down by adhesions. Constricted at proximal end. Fibrotic.	6	11
14	25	—	No evidence of appendix.	C. g.	Appendix under liver and gall-bladder. Very long, œdematous, injected; concretion in tip.	25	14
			Lassitude and General Malaise (Five Cases).				
5	25	No observations made.	Repeated marked tenderness at lower cæcal pole.	—	Long, kinked appendix. Considerable fibrosis.	25	5
12	18	Hyper-activity of duodenum.	Appendix not filling properly. Cæcum tender.	C. gs.	Adhesions. Abnormally long, very injected appendix containing purulent material. General œdematous mucosa. Submucous hæmorrhages.	18	12
3	25	Ptosis. Delay at pylorus. Gastric hypotony.	Appendix not empty four days after meal.	—	Appendix very long, fibrotic. Coiled on itself. Multiple adhesions.	25	3
9	12	Duodenum ? kinked second stage.	Appendix not empty 30 hours after meal. Irregular outline. Tenderness of cæcum.	C. gs.	Large, swollen, very injected appendix. Multiple submucous hæmorrhages.	12	9
13	37	Hyper-activity of duodenum.	Appendix only slightly filled.	—	Multiple adhesions. Appendix opaque and thickened with congested vessels.	37	13
			Lassitude and General Malaise and Upper Abdominal Discomfort (Eight Cases).				
10	27	Stomach hypotonic, dilated.	Appendix not seen.	—	Multiple adhesions around appendix.	27	10
6	20	Some dilatation of stomach, and gastric hypotonia.	Appendix filled, broken up. Cæcum tender.	C. g.	Appendix very œdematous. Multiple petechial hæmorrhages in mucosa. Distal one-third fibrotic.	20	6
4	27	Some ptosis. Moderate pause at pylorus.	Appendix not empty 3½ days after meal.	C. gs.	Long appendix, middle one-third filled with muco-pus. Terminal one-third fibrotic.	27	4
8	22	Duodenum fills at once. Second stage big and somewhat dilated. A little delay at duodenal-jejunal flexure.	Appendix kinked, irregular outline.	—	Appendix kinked at cæcum. Concretion in tip. Fibrosis of terminal one-third.	22	8
7	21	Rapid emptying of stomach.	Very little evidence of appendix.	C. gs.	Adhesions. Long fibrotic appendix filled with thick, almost solid fæces.	21	7
17	35	—	,, ,, ,,	C. gs.	Thickening and fibrosis of distal half of appendix.	35	17
16	16½	To and fro movement in duodenum.	Appendix partly filled. Only slightly movable.	C. gs.	Large, fat appendix, constricted in its centre.	16½	16
18	17	Fair amount of delay at pylorus. Some antiperistalsis is present in second stage of duodenum. Duodenum in second and third stages shows a little dilatation.	Fixed cæcum. Tenderness. Some barium in appendix 30 hours after meal.	C. gs.	Free fluid. Multiple adhesions. Appendix long, injected, œdematous proximal two-thirds, barium in distal one-third from meal given five days earlier.	17	18

C. gs. = calcareous glands.

deferred the operation for three months' medicinal treatment. During this period the patient had four weeks' holiday and continuous nervine and general tonics, particular attention being paid to the alleviation of his constipation. On May 3rd he reported continuous headaches. He slept like a log and awakened heavy-headed with a dry mouth. He had some flatulency. A fortnight later he reported awakening extremely heavy-eyed, with a nasty tangy taste in his mouth, so that he had to drink quantities of water first thing. On June 7th he developed a spread of small angry boils at the nape of the neck. On July 10th he had a further consultation with the surgeon, who agreed to perform appendicectomy.

The appendix was removed on July 31st. It was large, fat, and constricted in its centre. Four months later the patient had no evening fatigue, no headaches, and very slight flatulency. He was full of energy and had no disagreeable taste in his mouth. His general health had improved and he was less constipated.

CASE 18, a lad aged 17 years, felt "sickish" during the afternoon of Nov. 17th, 1930, and went to bed early. He had fitful sleep and awakened about 3 A.M. "feeling like death," and was violently sick. Physical examination showed marked increased resistance over the whole of the right rectus, particularly the upper segment, and increased resistance also in the left rectus. There was no pyrexia. After he had been in bed on milk diet and medicinal treatment for one week the upper two segments of the right rectus were still resistant. He had had occasional twinges of abdominal discomfort, and nausea for a short period on two occasions.

A barium meal on Nov. 26th showed the following abnormalities:—(1) A fair amount of delay at the pylorus. (2) some antiperistalsis in the second stage of the duodenum; (3) the duodenum at the second and third stages shows a little dilatation. 7½ hours after ingestion: (4) the cæcum lies an inch or two below the brim of the true pelvis; appendix not filled. 30 hours after ingestion: (5) some meal still in the appendix; (6) close to the appendix, calcareous glands are visible; (7) tenderness on palpation; (8) appendix is filled, but appears partly hidden by the cæcum and is not freely separated from it. The radiologist further reports: (9) "Cæcum fixed by adhesions caused either by calcareous glands or by the adherent appendix."

Appendicectomy was performed on Dec. 1st. Free fluid was found in the peritoneal cavity, and adhesions bound the cæcum to the posterior abdominal wall. The cæcum and ileum were very injected, and the appendix very œdematous in its proximal two-thirds; its distal one-third contained some barium from the meal given five days previously. There was an area of about 2 in. by ½ in. of inflammatory lymph on the terminal portion of the ileum and parietal peritoneum.

Conclusions.

Perhaps the two cases of outstanding importance to substantiate my claim for the recognition of the "poisoning appendix," and for appreciating the sequelæ suggested earlier, are Cases 13 and 18. Case 13 shows that a non-functioning appendix, as shown by X rays on March 21st, 1929, which had given toxæmic symptoms for two and a half years, had the pathological condition of the cæcal area altered, over a period of eight months, from one of a normal freely movable cæcum to one wherein the cæcum was bound down by adhesions, during which time the only clinical evidence was an intensification of the symptoms. In Case 18 we have definite evidence of physiological reaction in the upper abdominal tract with pathological changes around the appendix—viz., adhesions and calcareous glands—which must have been extant prior to nine days after a subacute attack; as well as operative evidence of the genuineness of the actual subacute attack.

Cases 1, 2, 11, 14, and 15, with histories of pyrexia and vomiting, but without any abnormal physical sign other than that described here for the first time, would be entitled to the convenient diagnosis of "gastric influenza." They suggest that this diagnosis has been made too freely, and that many cases so labelled have been really none other than a subacute exacerbation of the "poisoning appendix." One would be justified in stating that Cases 4, 6, 7, 9, 12, and 18 must inevitably have terminated in acute appendicitis with abscesses.

Cases 4, 6, 12, and 18 have the additional interest of all being in one family. In 1912 a baby belonging to this family died after an operation for appendix abscess and general peritonitis. Three months later another child had an attack of appendicitis. This attack was treated, and subsided, but kept recurring in subacute attacks until recently a chronically diseased appendix was removed. Furthermore, a son in this family had chronic appendicitis and duodenal ulcer; appendicectomy was performed during the period covered by this series. Yet again, the mother of the family and one other daughter also had appendicectomy, making a total of eight operations for appendicectomy within 22 months, four being for definitely chronic appendices, three for poisoning appendices, and one for poisoning appendix with subacute exacerbation.

One cannot overlook the importance of changes in the upper abdominal tract accompanying the non-functioning appendix. Twelve cases furnished this evidence.

Recognition of the "poisoning appendix" should considerably lower the surgical mortality in cases of appendicectomy, for a large percentage of cases would be operated upon before the predominance of peritoneal symptoms. It should also negative the disrespect with which physicians view operations for chronically diseased appendices; a disrespect begotten of the indisputable fact that in a large percentage of cases the patients appear to have derived no benefit at all from the operations. The probable explanation of this absence of beneficial results is that the patients' systems have become so impregnated with the by-products of poisoning from the appendix as to render removal of the cause incapable of obliterating the effects.

Investigations into the histories of patients with acute appendicitis have invariably shown that the patients complained of some phase of general malaise—which on close analysis would evidence toxæmic origin—over a period, either long or short, before the onset of acute symptoms. Acute appendicitis must, therefore, be regarded as a preventable calamity, not as a "bolt from the blue." Transition from physiological utility to pathological decay is slow but sinister, and leaves in its wake:—

(*a*) Symptoms of an absence of well-being, frequently indefinable but here classified as general malaise, and usually ineffectually treated by general tonics.

(*b*) The same general symptoms with upper intestinal tract symptoms superimposed.

(*c*) A physical sign described here for the first time; increased resistance of the upper segment only of the right rectus.

(*d*) Conclusive X ray evidence of the appendix not functioning properly.

Confirmation of the tentative diagnosis depends entirely upon the competence of the radiologist. It is unfortunate that the investigation is not within the reach of all. Were expense not a material factor, many more cases would have been investigated.

With one exception, all the X rays have been taken and reported upon by one radiologist, and with one exception all the operations have been performed by one surgeon, to both of whom I am very gratefully indebted.

STOURBRIDGE CORBETT HOSPITAL.—The Mayor of Stourbridge, Alderman H. E. Palfrey, last week cut the first sod of an extension, and was paid a wage of 1s. 1½d. for his spade work. The addition will provide 28 extra beds and the corresponding additional accommodation for nurses.

incapable of carrying on with his work without periods of rest. He had lost weight. In 1927 his condition was believed to be due to myocardial failure, but this opinion was negatived by the report of the cardiac specialist. Rest and tonics were prescribed. In October, 1928, he had some lower abdominal discomfort, and complained of constipation and of feeling the whole of the cæcum against the abdominal wall.

The cæcum and descending colon were thickened and easily palpable, but there was no tenderness. A barium X ray meal on March 21st, 1929, showed the following abnormalities:—(1) Hyper-activity of the duodenum. 6½ hours after ingestion: (2) cæcal pole very movable. Appendix partly but only slightly filled. 8½ hours after ingestion: (3) freely movable appendix not obvious either on film or on screen. 48 hours after ingestion: (4) cæcum contains some barium mixed with food. The radiologist further reports: (5) "Appendix did not fill like 90 per cent. of normal ones, but that is the only point against it."

The condition was believed to be due to visceroptosis and overwork. One month's rest in a nursing home with abdominal massage was prescribed, preceded by two weeks' holiday. The constipation was entirely relieved, but the "fatigue" continued unrelieved.

Six months later, the fatigue condition having become unutterably intolerable, and the patient totally unable to carry on with his work, appendicectomy was decided upon. At operation on Nov. 22nd, 1929, the cæcum was found adherent to the abdominal wall. There was a mass of adhesions round the appendix, which was twisted on itself, the two loops being adherent. The appendix was opaque and thickened, with congested vessels. Twelve months later the toxæmic symptoms had entirely disappeared, and the patient was very well.

GROUP IV.—MALAISE, LASSITUDE, AND ABDOMINAL SYMPTOMS.

CASE 16, a boy aged 16½ years, stated that from Christmas, 1929, to February, 1930, he had had discomfort in the epigastrium a quarter of an hour after meals, but no vomiting. On one occasion he had had acute pain round the umbilicus, lasting for five minutes. This had doubled him up, but had not been accompanied by vomiting. He had had constipation for 12 months.

Increased resistance was found in the upper two segments of the right rectus. A barium meal on Feb. 26th, 1930, showed the following abnormalities:—Excessive peristalsis, to-and-fro movement in the duodenum. 7 hours after ingestion: (1) appendix partly filled; ? kinked; no tenderness. 8½ hours after ingestion: (4) appendix slightly movable; no tenderness. The radiologist further reports: (3) "Previous to giving the meal, a film of the abdomen shows a large calcareous mesenteric gland."

Although in this case the diagnosis of "poisoning appendix" was made, the surgeon did not agree, and

Case	Age.	Shown by X rays: alterations from normal.		—	Main features at operation.	Age.	Case
		In upper abdominal tract.	In cæcal area.				
			Symptomless Pyrexia (Two Cases).				
1	38	—	Appendix not seen. Cæcum not movable. Tenderness.	C. gs.	Free fluid. Appendix injected, œdematous. Cæcum bound down by adhesions.	38	1
15	11	Excessive peristalsis.	Appendix not filling properly.	C. gs.	Multiple adhesions.	11	15
			Pyrexia and Vomiting (Three Cases).				
2	51	Gastric rate of emptying unduly rapid.	Fixed appendix. Cæcum tender. Concretions.	C. gs.	Appendix bound down by adhesions middle two-thirds. Fibrotic	51	2
11	6	No observations made.	Appendix never properly filled. Cæcum not movable. Tender.	C. gs.	Appendix bound down by adhesions. Constricted at proximal end. Fibrotic.	6	11
14	25	—	No evidence of appendix.	C. g.	Appendix under liver and gall-bladder. Very long, œdematous, injected; concretion in tip.	25	14
			Lassitude and General Malaise (Five Cases).				
5	25	No observations made.	Repeated marked tenderness at lower cæcal pole.	—	Long, kinked appendix. Considerable fibrosis.	25	5
12	18	Hyper-activity of duodenum.	Appendix not filling properly. Cæcum tender.	C. gs.	Adhesions. Abnormally long, very injected appendix containing purulent material. General œdematous mucosa. Submucous hæmorrhages.	18	12
3	25	Ptosis. Delay at pylorus. Gastric hypotony.	Appendix not empty four days after meal.	—	Appendix very long, fibrotic. Coiled on itself. Multiple adhesions.	25	3
9	12	Duodenum ? kinked second stage.	Appendix not empty 30 hours after meal. Irregular outline. Tenderness of cæcum.	C. gs.	Large, swollen, very injected appendix. Multiple submucous hæmorrhages.	12	9
13	37	Hyper-activity of duodenum.	Appendix only slightly filled.	—	Multiple adhesions. Appendix opaque and thickened with congested vessels.	37	13
			Lassitude and General Malaise and Upper Abdominal Discomfort (Eight Cases).				
10	27	Stomach hypotonic, dilated.	Appendix not seen.	—	Multiple adhesions around appendix.	27	10
6	20	Some dilatation of stomach, and gastric hypotonia.	Appendix filled, broken up. Cæcum tender.	C. g.	Appendix very œdematous. Multiple petechial hæmorrhages in mucosa. Distal one-third fibrotic.	20	6
4	27	Some ptosis. Moderate pause at pylorus.	Appendix not empty 3½ days after meal.	C. gs.	Long appendix, middle one-third filled with muco-pus. Terminal one-third fibrotic.	27	4
8	22	Duodenum fills at once. Second stage big and somewhat dilated. A little delay at duodenal-jejunal flexure.	Appendix kinked, irregular outline.	—	Appendix kinked at cæcum. Concretion in tip. Fibrosis of terminal one-third.	22	8
7	21	Rapid emptying of stomach.	Very little evidence of appendix.	C. gs.	Adhesions. Long fibrotic appendix filled with thick, almost solid fæces.	21	7
17	35	—	,, ,, ,,	C. gs.	Thickening and fibrosis of distal half of appendix.	35	17
16	16½	To and fro movement in duodenum.	Appendix partly filled. Only slightly movable.	C. gs.	Large, fat appendix, constricted in its centre.	16½	16
18	17	Fair amount of delay at pylorus. Some antiperistalsis is present in second stage of duodenum. Duodenum in second and third stages shows a little dilatation.	Fixed cæcum. Tenderness. Some barium in appendix 30 hours after meal.	C. gs.	Free fluid. Multiple adhesions. Appendix long, injected, œdematous proximal two-thirds, barium in distal one-third from meal given five days earlier.	17	18

C. gs. = calcareous glands.

did the albuminuria disappear before delivery, in spite of active treatment.

It is difficult to understand how the widespread belief that albuminuria under treatment commonly clears up before the birth of the child has arisen, and I can only think that it is based upon careless observations, in which the albuminuria accompanying a transitory pyuria has been mistaken for an essential albuminuria. No case of albuminuria should be accepted unless a microscopical examination of the urine has been made for pus cells. It is sometimes difficult to decide how much albumin we may attribute to the presence of pus but this difficulty is uncommon, since a consideration of all the accompanying signs and symptoms will usually point to the correct diagnosis of either albuminuria of pregnancy or pyelitis or both. So long as the possible source of error is constantly borne in mind, error is unlikely; but immediately it is ignored mistakes in diagnosis and fantastic beliefs in "simple albuminuria" and "frequent cures" before delivery of the patient will inevitably result.

It is clear, therefore, that the majority of patients suffering from albuminuria must stay in bed from the very first time that albumin is discovered until after delivery. If we examine our treatment critically we cannot but be ashamed of our carelessness of end-results. That this carelessness is universal is shown by the fact that it is demonstrated in the annual reports of many of the big midwifery institutions of Great Britain. Under the section of albuminuria some of these reports have a heading showing the result of the urine test at the time the patient leaves hospital. In many cases the space is left blank (which possibly means that the urine was not tested), but where a record is made we can draw definite conclusions. Table V. is made up from the latest available annual reports of five of the hospitals where the necessary information is published.

TABLE V.

Total cases of albuminuria.	Result of urine test at time of discharge.		
	No record.	Alb. present.	No alb. present.
236	59	118	59

These hospitals have been chosen at random as representing the best type of treatment at present practised in Great Britain. It is seen, therefore, that in cases where a record is available nearly 70 per cent. of the patients are discharged from hospital before the albuminuria has cleared up. Some of these, no doubt, are suffering from chronic nephritis, but this can account only for relatively few cases. If the late results of albuminuria were satisfactory there might be some justification for allowing a patient with an acute renal disease to get up before all signs of disease had disappeared; but as in fact the present-day results are not satisfactory, surely there is reason to make an extra effort to improve them.

It is impossible to give any comparative figures showing the late results in patients who have, and have not, been allowed to leave bed before the albuminuria has disappeared, since it is too soon to have collected a large enough series of the latter. In the light of our present knowledge, the least we can do is to treat albuminuria of pregnancy with the care that we should bestow upon a case of acute nephritis. Except where there is good reason to believe that a chronic nephritis antedated the pregnancy, no lying-in mother who has suffered from albuminuria should be allowed to leave her bed until her albuminuria has entirely cleared up. This may be a counsel of perfection, and economic pressure amongst hospital patients may be a serious difficulty, but if we allow a patient to get up before this time, at least we must not delude ourselves that she is having the best treatment. The value of this rest is probably mainly that it reduces the patient's endogenous protein metabolism to a minimum, and therefore reduces the work that the damaged kidney has to do in excreting nitrogenous waste products.

Diet.

The importance of diet in the treatment of albuminuria has been stressed frequently enough, but unfortunately there is no uniformity of opinion as to the best diet to adopt, mainly because its value is differently interpreted by various observers. Admitting, as we must, our ignorance of the ætiology of "toxæmia of pregnancy," it seems unwise to adopt this or that diet because of some supposed influence in the production of an unknown toxin. The importance of renal disease, even though it be secondary in these cases, is undoubted, and since protection of renal function is an aim that can be furthered by dietetic measures it seems rational to adopt a diet which entails the least amount of work on the part of the kidneys.

This consideration has led me to adopt a diet that is as nearly as possible protein-free, and although I do not suggest that there is anything new in this type of diet, yet I would stress again that its adoption is based solely upon a recognition of the most important result of toxæmia of pregnancy—i.e., kidney damage. The diet is in no way dependent upon the possible cause of the toxæmia, and its "rationale" is uninfluenced by mere speculations into the ætiology of the disease.

A full mixed diet entails extra work for the kidneys for two reasons: first, on account of its specific dynamic action, it causes an increase in basal metabolism (especially marked where proteins figure largely in the diet) and this entails an increased excretion of nitrogen and salts; furthermore, in the case of nitrogenous foods, excess over and above the minimum necessary to replace the results of endogenous protein katabolism must be excreted quantitatively by the kidney. By diminishing the diet we can therefore diminish the work thrown upon the kidney, but this principle cannot be carried to the extreme of complete starvation, since in this condition the patient is forced to live on her own tissues to supply the needs for her basal metabolism, and thus immediately becomes carnivorous. It is therefore wrong in severe cases of albuminuria to enforce complete starvation. It should be our aim to supply as nearly as possible the basal caloric requirements of the body in a form of food which does not lead to any increase in work by the kidney. Such a food is sugar. A further advantage in adopting a sugar diet, as opposed to complete starvation, is that it avoids completely the onset of ketosis, a condition which is probably dangerous and certainly most distressing to a patient already severely ill with albuminuria of pregnancy.

Glucose is the sugar of choice, since it is less sweet than cane sugar, and for administration by mouth commercial "liquid glucose" (containing about 60 per cent. of carbohydrate) is perfectly satisfactory. A solution of 4 oz. of liquid glucose in a pint of water flavoured with lemon juice makes a lemonade which if not a pleasant drink, is at least tolerable; and it has the advantage that if four or five pints a day are consumed the patient receives about 1000 calories without imposing any extra work on her kidneys. Much less than this is, of course, sufficient to prevent a ketosis, but with this amount of glucose a tolerant patient can be starved of all other food for several days continuously. In practice it is found that alimentary glycosuria does not arise if the "lemonade" is distributed fairly evenly throughout the day. This is the minimum diet for the treatment of albuminuria, and it can be augmented by adding solid carbohydrates, then fats, and—in order to make the diet less uninteresting—a small amount of protein may be allowed as a concession, but the aim is to restrict diet as nearly as possible to carbohydrates.

The following standard diets are in use at Guy's Hospital, and they are given in detail to illustrate that a fairly attractive low protein diet can be achieved in hospital practice.

STAGE 1.—About 1000 calories. Lemonade and glucose four to five pints (glucose 4 oz. to the pint); oranges, 4.

STAGE 2.—About 1500 calories. Fluids not less than five pints (including glucose lemonade); oranges or apples, 4.

Breakfast.—Toast, 2 oz.; butter, ½ oz.; marmalade, 1 oz.; tea.

Lunch.—Cocoa or coffee.

Dinner.—Sandwiches (marmite, cress or lettuce, &c., 2 oz.); pudding, 4 oz.; jam, 1 oz.

Tea.—Bread, 2 oz.; butter, ½ oz.; jam, ½ oz.; tea.

Supper.—Biscuits, 1 oz.; cocoa.

STAGE 3.—About 1800 calories. Fluids and fruit as Stage 2.

Breakfast.—Toast, 2 oz.; marmalade, 1 oz.; butter, ½ oz.; tea.

Lunch.—Cocoa or coffee.

Dinner.—Sandwiches, 4 oz.; vegetables, ad. lib.; pudding, 4 oz.; jam, 1 oz.

Tea.—Bread, 2 oz.; sandwiches, 1 oz.; tea.

Supper.—Biscuits or sandwiches, 1 oz.; cocoa.

STAGE 4.—About 2200 calories. As Stage 3, with daily addition of half pint of milk; fish, 4 oz.; egg, 1.

In Stage 2 and Stage 3 milk is restricted to that necessary for beverages, since the protein content of milk is high, and it is allowed in these small amounts only in order to make the diet less dull for a patient who may have to confine herself to it for several weeks on end. Every patient, when first admitted to hospital, is put on Stage 1 diet for the first 24 hours in order to obtain an estimate of the blood pressure and albumin content of the urine under standard conditions. The subsequent diet depends upon a number of considerations but, generally, speaking, she remains on Stage 1 diet as long as her blood pressure remains high (above 150 mm.) or the amount of albumin in the urine is great (above 2 parts per 1000). Improvement beyond this stage is generally looked upon as cause for promotion to Stage 2 diet, and the patient then continues with this until she is delivered, except in the rare instances where the albuminuria clears up entirely before delivery, when she may proceed to Stage 3 diet.

Stage 3 diet is, as a rule, reserved for patients immediately after delivery, in whom it is still necessary to curtail the protein but in whom a fairly liberal diet is required to encourage lactation. Stage 4 diet is intended for patients who have recovered completely after delivery. When the last trace of albumin has disappeared from the urine the patient is allowed to get up and to enjoy this augmented diet. She is advised to keep to this as a rule for a further four to eight weeks, after which she is free from all restriction.

Elimination of Toxin.

While attempts to relieve the kidney of any excess of work are undoubtedly rational, we are on less certain ground when we attempt to "eliminate toxins" in cases of albuminuria. The very existence of a toxin is still unproven, and there is no direct evidence of how it is excreted. In spite of the absence of experimental proof, however, the clinical value of purgatives is well established, and in all cases it is important to secure one or two loose evacuations of the bowels daily. This is best achieved by saline purgatives, and magnesium sulphate in doses of 2 drachms should be given as required; usually once daily is sufficient. The one disadvantage of this régime is that after some time (four to eight days) the patient may become uncomfortable from abdominal distension due to the prolonged continual administration of magnesium sulphate. This can be overcome by giving 48 hours' rest from the saline aperient and substituting for it small doses of cascara sagrada, after which the saline can be continued for a further period.

The advisability of inducing diaphoresis has been questioned, since it is held by some that the loss of fluid in this way merely concentrates the toxins in the body. As there is no experimental evidence to help us we are compelled to rely on clinical impressions for guidance, and it has been repeatedly observed that in cases of severe toxæmia profuse sweating is usually a good sign. For this reason, in severe cases of albuminuria where there is threatened suppression of urine, it is advisable to induce sweating by means of hot blankets, or, if available, by an "electric cradle," but it is not necessary to make use of diaphoresis in less severe cases.

The possible excretion of toxins by way of the kidneys calls for the administration of large amounts of fluid, and in any case, even if the intake of fluid is not followed by a commensurate diuresis, it must result in a dilution of toxins in the body. Clinically, the result of ingestion of large amounts of fluid are certainly good. For this reason the patient should be encouraged to drink at least five pints a day. On Stage 1 diet this will necessitate her taking a pint of water in addition to her four pints of "glucose lemonade." On the other diets she may choose her fluid from water, barley-water, lemonade, and other similar beverages.

Drugs.

With the possible exception of alkalis, there are no drugs of any particular value in the treatment of albuminuria, apart from those necessary for the production of catharsis. Osman and Close,[2] in their general study of renal disease, have drawn attention to the value of large doses of alkalis in the treatment and prevention of nephritis, and have suggested the use, inter alia, of alkalis in the treatment and prevention of albuminuria of pregnancy. As is now well known, Osman's "alkali treatment" is a very different thing from giving a fixed dose of potassium citrate to a patient three times a day, and its application involves careful and constant observation on the pH of the urine, with occasional control estimations of the bicarbonate reserve of the blood. In his view, the employment of inadequate doses of alkali is useless. While the results of Osman's investigations into the value of alkalis in albuminuria of pregnancy are as yet incomplete, it is too soon to attempt to form an opinion on this line of treatment. We must wait until sufficient evidence has been obtained to warrant either its adoption or its omission from the methods at our disposal. Irresponsible dabbling with alkalis can lead to no good.

Induction of Labour.

When conservative methods have failed in the treatment of albuminuria associated with pregnancy, there is general uniformity of opinion that induction of premature labour should be adopted as a radical measure. Much difference of opinion exists as to when conservative treatment is to be considered a failure. In the light of our knowledge of the remote effects of this disease on the kidneys, we must look upon the conservative treatment as a failure if eclampsia supervenes, if chronic nephritis results, and also if the patient develops an albuminuria with a subsequent pregnancy in spite of being apparently healthy in the interval. Furthermore, if the fœtus dies in utero, conservative treatment has obviously failed in its object.

Unfortunately, induction of labour does not offer a solution to the difficulties in every case, but it is a measure which deserves a wider application than it has been given in the past. It was formerly considered valuable only in so far as it might prevent the onset of eclampsia, but now that the other sequelæ of albuminuria are recognised, there is good reason to expect that improvement in the late results of pregnancy toxæmia will follow the wider use of induction of premature labour in certain cases.

Attention has been drawn already to the fact that the incidence of recurrent albuminuria can to some extent be controlled by early induction of labour in the first toxæmic pregnancy, and also that the incidence of chronic nephritis amongst previously healthy women can be appreciably diminished by the same means. So far as the welfare of the child is concerned it has been shown that maceration owing to delay in induction is in fact a greater danger than the risk of death from prematurity resulting from induction.

Armed with these facts, we can proceed to consider general principles as to the indications for induction of premature labour in cases of albuminuria. These indications can never become hard-and-fast rules, since the relative importance placed upon the value of the infant and the risk to the mother must vary with each individual patient, but they are to be taken as a working basis, to be modified in special circumstances. They can be set out as follows.

Labour should be induced:

1. In any severe toxæmia (blood pressure greater than 170 mm.) which does not respond within 2 or 3 days to full treatment—i.e., rest in bed on Stage 1 diet.

2. In any toxæmia of moderate severity (blood pressure 150 mm.) when progressive improvement ceases to take place. It is not sufficient that the blood pressure and albumin content of the urine should remain constant from day to day to justify the withholding of induction.

3. In any toxæmia, no matter how mild, that has lasted (as proved by the persistence of albuminuria) more than two weeks.

4. In patients known to have a chronic nephritis, as soon as the patient is first seen.

5. In any case where a previous pregnancy has resulted in a macerated fœtus, as soon as the fœtus seems big enough (32 to 34 weeks) to stand a reasonable chance of survival.

It must be emphasised again that these indications are to be modified in special cases, but they are set out dogmatically as a standard that we should try to attain for the sake of the mother. It may, in special circumstances, be justified to allow her to take risks of permanent renal damage for the sake of a viable fœtus, but let us not delude ourselves about the issue. Delay in induction may be necessary for the sake of the fœtus in some cases, but it is the mother who pays for this advantage. That she may pay willingly is no reason for belittling the cost.

Summary.

In view of the unsatisfactory results that are liable to follow upon albuminuria complicating pregnancy, the necessity for more whole-hearted treatment has been stressed. The futility of basing a treatment upon mere speculations as to the ætiology of the disease has been discussed, and a treatment the rationale of which depends upon what we know of the late results has been outlined. This treatment aims primarily at protecting the kidneys against the "toxæmia," and it has as its basis, rest, protein-free diet, and early induction of labour. These three measures are discussed at length, and although each is a well-recognised method of treatment, a plea is made for their more conscientious application, in an attempt to improve the late results which are at present so unsatisfactory.

THE ANTIRACHITIC VALUE OF IRRADIATED YEAST.

By Stanislaw K. Kon, Ph.D.

(From the Biochemical Department, State School of Hygiene, Warsaw.)

The results of the administration of irradiated yeast to rachitic children have been reported in a previous communication.[1] The present paper deals with the evaluation of the antirachitic potency of irradiated yeast by means of the rat test.

It is well known that, owing to the easy storage of vitamin D, unknown variable amounts of this factor are present in the body of young rats when placed on a rachitogenic diet, and that the time necessary for the production of rickets is a function of the maternal diet. Similar difficulties are encountered in the case of vitamin A. To obviate them Nelson[2] has recently suggested a simple and ingenious procedure. He found that, when mother and young were transferred to a vitamin-A-free diet when the young were 16 to 18 days old, the onset of symptoms of vitamin A deficiency in the young seemed to be independent of the amount of vitamin A given to the mother during the entire period of lactation. Some difficulties having been encountered in our laboratory in the production of rickets in young rats when transferred directly from the stock diet* to the rachitogenic ration, the method of Nelson was resorted to with excellent results. On the 16th day of lactation mother and young were changed from the stock diet to a similar diet from which the butter had been omitted; the young were weaned when weighing from 55 to 65 g. and placed on the 2965 rachitogenic diet of Steenbock. In every case line test rickets were produced with great constancy in the course of three weeks.†

The irradiated yeast was prepared under exactly the same conditions as previously described.‡ For testing, graded amounts of the yeast were weighed out, intimately mixed with 50 g. of diet 2965 and fed to rachitic rats which were kept in separate cages. When completely consumed, the mixture was followed by the untreated 2965 ration, and after ten days the rats were killed, and the radii and ulnæ examined by the line test technique.§ Amounts from 1 to 20 mg. of irradiated yeast were tested and the results are shown in Figs. 1 and 2. As appears from the drawings, a total dose of 1 mg. (or 0·1 mg. daily) is sufficient to produce a narrow line of calcification, and is therefore equivalent to one rat unit as defined by Steenbock. This is in perfect agreement with the results of Steenbock,[5] a result certainly striking, especially as the yeast used in Madison and Warsaw respectively was obtained from quite different sources, and the conditions of irradiation were not exactly the same in the two places.

---

* The diet was a modification of Steenbock's stock diet[3] and had the following composition: whole ground rye 70, linseed cake 15, butter 5, dried ox liver 3, calcium carbonate 0·5, sodium chloride 0·5. The diet was supplemented with 10 per cent. by weight of dried whole milk and fresh carrots.

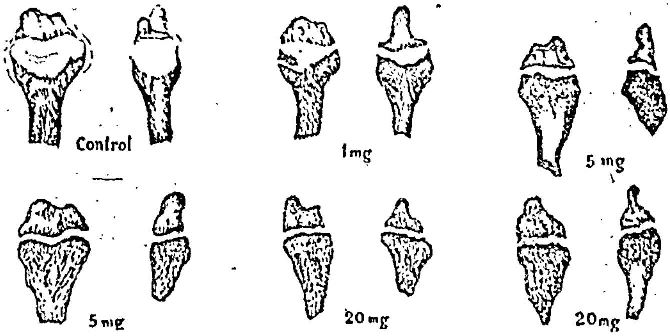
† According to the "tests" of the Pharm. Soc. of Gt. Brit.[4] butter should be omitted from the diet of mothers whose young are to be used for vitamin D tests.

‡ By inadvertance the distance from the source of light was not given in the first paper. The distance was 50 cm.

Stability of Vitamin D in Irradiated Yeast.

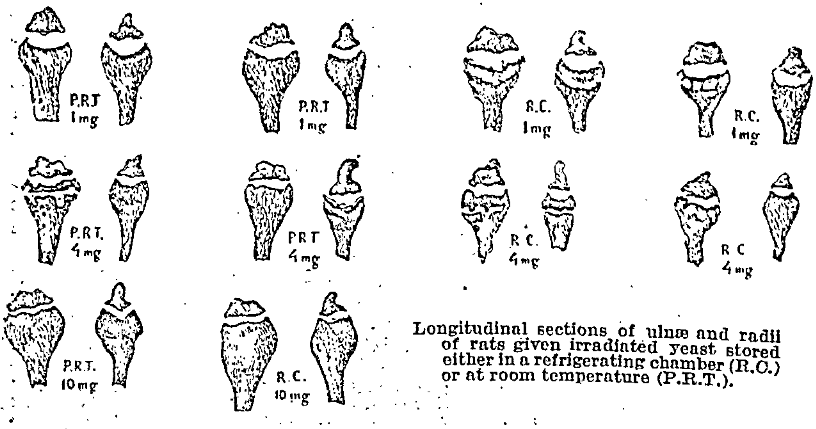
A batch of yeast irradiated under standard conditions on Nov. 19th, 1929, was divided into two parts: one was placed in a glass-stoppered bottle in a cold store at a temperature of −2° C., the other, wrapped in paper, was kept at room temperature in the laboratory. After six months (on May 21st, 1930) the two preparations were tested for their vitamin D content. The results are given in Fig. 3. It is evident that no difference can be noticed between the activity of the two batches. There is no separate line of calcification in the case of rats given 1 mg. of P.R.T. yeast—but the width of the metaphysis approximately corresponds with a "narrow line" test. A comparison with Figs. 1 and 2 shows that hardly any loss of activity took place in the course of six months, 1 mg. of irradiated yeast still giving after this time a narrow line of calcification or a medium metaphysis.

FIG. 2.



Longitudinal sections of ulnæ and radii of rats given irradiated yeast.

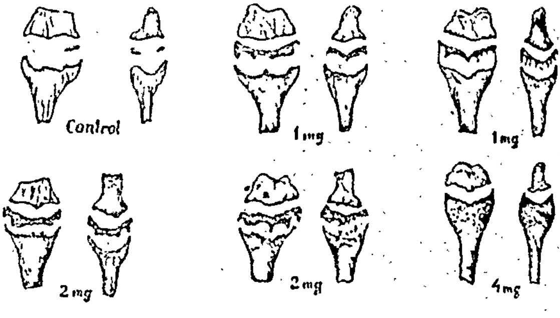
FIG. 3.



Longitudinal sections of ulnæ and radii of rats given irradiated yeast stored either in a refrigerating chamber (R.C.) or at room temperature (P.R.T.).

The batch kept at room temperature was retested after another four months had elapsed (ten months after irradiation) on Sept. 23rd, 1930, and no noticeable deterioration was observed, 1 mg. of the preparation still giving a narrow line. These drawings are omitted in order to save space.

FIG. 1.



Drawings of longitudinal sections of ulnæ and radii (treated with silver nitrate and exposed to light) of rats given irradiated yeast.

The results indicate that irradiated yeast retains for a long time its antirachitic properties and that it can be kept at ordinary temperature and exposure to air. This is in contradiction to the results of Kirsch,[6] who found that irradiated yeast rapidly deteriorated. He must have been working, however, with an inadequate preparation, for he had to administer very high doses (0·5 to 1 g. daily) in order to obtain positive results.

Problem of Overdosage.

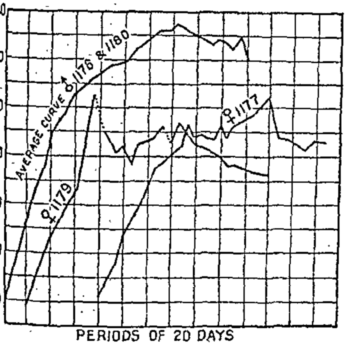
The question whether untoward symptoms observed in infants and in experimental animals receiving an overdosage of irradiated substances is due to hypervitaminosis or is caused by a toxic factor distinct from the vitamin has not yet been answered with certainty.[7 8 9] It is obvious that the irradiation of such a complex substance as yeast, in the presence of oxygen and with polychromatic ultra-violet light, leads to the formation of a variety of products other than vitamin D. On the other hand, some observers have voiced the opinion that non-irradiated ergosterol is per se harmful.[10] Should this be true, it might have an important bearing on the use of yeast in general and of irradiated yeast in particular, for there is no doubt that a large percentage of unchanged ergosterol is present in irradiated yeast. It was thought highly necessary to determine experimentally whether and what overdosage of irradiated yeast would be harmful to the rat.

---

§ The author had the privilege of spending six months in the laboratory of Prof. Steenbock and of acquiring the technique of the line test, as carried out there.

Twelve rats from two litters were therefore distributed into three batches, each batch consisting of two males and two females, with the exception of batch 1, containing three males and one female. The first batch was placed on our usual stock diet (diet 33), the second was given the stock diet plus an addition of 10 per cent. of non-irradiated yeast (diet 57), while the third batch was given the stock diet with an addition of 10 per cent. of irradiated yeast (diet 58). In each batch the males and females were kept together; pregnant does were isolated; in each litter the young after birth were reduced to six, weaned in the customary way when three weeks old and transferred, males and females together, to separate cages, where they were offered the parental diet. The experiment lasted 6½ months (200 days). During this time one female on diet 57 (non-irradiated yeast) had two litters but did not suckle them‖; the other female had four litters (35 young) of which three were suckled after reduction of the litters to a maximum of six, and seventeen young were weaned. On diet 58 (irradiated yeast) one female had two litters, one of nine young and one of two; after reduction of the former all eight were weaned. The other female had no litter, but normal fœtuses were found in utero at autopsy at the close of the experiment.

FIG. 4.



Growth curves of first generation rats on diet containing irradiated yeast.

FIG. 5.

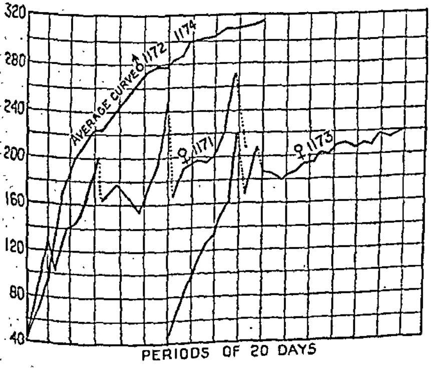


FIG. 6.

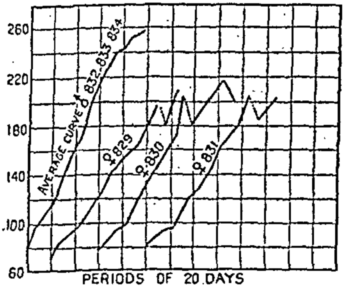
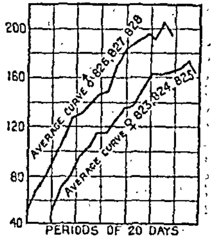


Growth curves of first generation rats (Fig. 5) and second generation rats (Fig. 6) on diet containing non-irradiated yeast.

The growth curves are given in Figs. 4 and 5 and it can be seen that while the animals on diet 57 grow steadily, those on diet 58 reached a plateau in the later part of the experiment, and then declined slowly. The differences are, if anything, more marked in the second generation, as shown by the growth curves of the first litters of does 1171 (diet 57) and 1179 (diet 58), Figs. 6 and 7. The better growth of the rats receiving non-irradiated yeast is clearly evident.¶

FIG. 7.



Growth curves of second generation rats on diet containing irradiated yeast.

On inspection at the close of the experiment they were found to be strong and lively animals, with silky fur and excellent muscular tonus, while the rats receiving irradiated yeast looked rather old for their age, felt flabby, the coats were not good, and the nose, front paws and the fur were to a greater or lesser degree soiled with blood. All three second generation females on the non-irradiated yeast (first litter of doe 1171) produced litters, and two weaned them successfully, while none of the second generation females on the irradiated yeast bore young. The reason for this failure is not clear, as motile sperm was found at autopsy in all the males and, by means of vaginal smears, ovulation was shown to occur in the females.

In an elaborate research Bills and Wirick[13] have reported definite injury in long-time experiments in rats receiving 4000 times the minimum antirachitic level of irradiated ergosterol, and they state that "All the females failed to reproduce following the third mating." A similar reproductive failure of rats receiving 50,000 times the normal daily dose of irradiated ergosterol, in addition to the Bills' modification of the Steenbock stock diet, was reported by Light, Miller and Frey.[13]

‖ Failures in lactation occurred also in stock colony females. This phenomenon has been discussed in a separate communication.[14]

¶ Curves for other second-generation rats are not given for economy of space. A second litter of five of doe 1171, born 2½ months before the termination of the experiment, grew at a perfectly normal rate, and the rats were apparently quite healthy and strong when disposed of. A third litter of six was weaned on the day the experiment was discontinued and averaged 46½ g. at that time. The second litter of doe 1179, consisting of two females, was unfortunately used for another experiment immediately after weaning.

Third generation young from the non-irradiated yeast group were apparently perfectly normal at weaning, when they were killed, it being necessary to discontinue the experiment. As mentioned, third generation young were not produced in the irradiated yeast group. The average daily food intake being estimated at 15 g. every rat must have consumed about 1·5 g. of yeast daily, corresponding, for the irradiated yeast animals, to an intake about 15,000 times larger than the minimal daily dose necessary for the production of a positive line test in a rachitic rat. The toxic effects of such an overdose are quite definite, but they are slight when compared with the dramatic course of massive overdosage with irradiated ergosterol. It seems that it may safely be concluded that irradiated yeast is not more toxic for rats, unit for unit, than irradiated ergosterol.

The results obtained do not seem to indicate that non-irradiated ergosterol, at least in the concentrations used in the present work, has any toxic properties. In fact rats receiving the addition of 10 per cent. of non-irradiated yeast did just as well as their mates on the stock ration alone. This observation is at variance with the findings of Jundell,[10] but certainly more work will have to be done on this important question before it is definitely settled.

Summary.

Yeast irradiated under specified conditions was found to contain one rat unit (Steenbock) in 1 mg. The preparation is stable and retains its potency for at least ten months at room temperature. A toxic effect could be elicited in rats by the prolonged administration of a modified Steenbock stock diet containing 10 per cent. by weight of irradiated yeast.

HIGHER PAYMENTS TO CONTRIBUTORY SCHEMES.—The board of delegates of the Birmingham Hospital Saturday Fund has unanimously agreed to raise the weekly contribution from 2*d.* to 3*d.*, after a proposal to graduate the payment according to income had been narrowly defeated.—The Sheffield and District Association of Hospital Contributors has also decided "to make an extra voluntary contribution at a flat rate of 1*d.* per week for an agreed period."

CORBRIDGE MATERNITY HOSPITAL.—Last week Lady Victoria Percy opened a maternity hospital at Corbridge, provided by the Northumberland County Nursing Association. The hospital consists of a considerably enlarged private house which has been used as a nurses' home by the Tynedale district nurses. In addition to a public ward there is a private ward and accommodation for private nurses. One of the wards is a memorial to the late Dr. Daniel Jackson, of Corbridge.

INSULIN AND PRESERVATIVE.

NOTE ON THE EFFECT OF INSULIN SOLUTIONS OF VARYING REACTION ON THE VIABILITY OF STAPHYLOCOCCI.

By PERCIVAL HARTLEY, M.C., D.Sc.

(From the National Institute for Medical Research.)

THE question of the addition of preservatives to insulin preparations dispensed in certain types of containers has been discussed recently in the correspondence columns of THE LANCET.[1,2,3,4] It is not proposed to enter into all the points raised in this correspondence; some of the writers assert definitely that the frequent daily injections of small amounts of phenolic preservative is harmful, while others are less positive, and urge, rather, that certain aspects of the question should receive further consideration and investigation. In view of recent experiences with antiseptic-free preparations of other therapeutic substances, it appeared to be of some importance to ascertain whether insulin solutions without such preservative can serve as a culture medium for micro-organisms accidentally introduced, and the importance of the question is increased by the fact that a great deal of the insulin used is administered by the patient himself. Is it possible for the diabetic patient, by any accident likely to occur in practice, to infect his phial of insulin at one withdrawal of a dose and, if he does so, will there be a danger of his injecting living micro-organisms in a later dose from the same bottle? It seemed desirable to investigate, firstly, whether micro-organisms can survive or multiply in the solutions of insulin as supplied; and, secondly, if these solutions are themselves germicidal, whether it is possible by accidental introduction of a small quantity of alkaline fluid to make the solution a culture medium for micro-organisms.

EFFECT OF REACTION ON BACTERIAL GROWTH.

It is claimed that the acidity of insulin solutions is a sufficient protection against infection, and this claim, together with the experience gained in this Institute, especially in the period immediately following the introduction of insulin, suggested that this particular point merited further investigation. During recent years samples of insulin have been returned to this Institute with a complaint that the product has become opalescent or that a precipitate has appeared in the fluid. Examination showed that the opalescence or precipitation was due, not to infection with micro-organisms, but to the fact that the reaction of the fluid had been changed so as to approach the isoelectric point of the insulin. Manufacturers of insulin have had a similar experience, and it is very probable that the cause of the opalescence or precipitation was the use of syringes which had been sterilised in alkaline solutions. Leyton and Poulton,[1] having in mind this possibility, suggest that an additional precaution might take the form of an instruction to the patient to the effect that, if the insulin does not look like clear water, it should not be used. The adoption of this proposal would exclude from further use some of the solutions which have been shown in these experiments to be capable of supporting the growth of staphylococci; but it has been found also that solutions of insulin which have been made sufficiently alkaline to overshoot the isoelectric point, so that they remain water-clear, certainly permit the survival, and possibly support the growth, of staphylococci.

Through the courtesy of three of the British manufacturers, samples of insulin have been supplied which are similar in all respects to their ordinary batches, with the single exception that the usual phenolic preservative had not been added. These samples are referred to below as B1 (32 units per c.cm.), B2 (20 units per c.cm.), and B3 (20 units per c.cm.). A preparation of preservative-free insulin made by a foreign manufacturer has also been available, and this is referred to as L (40 units per c.cm.); and one further sample for study, kindly supplied by this foreign manufacturer, was a preparation of the same insulin, L, containing 0·3 per cent. of tricresol.

As test organism a strain of *Staphylococcus albus* has been used. This has been subcultured daily into 10 c.cm. quantities of nutrient broth, and 24-hour old cultures have been used throughout the work. The dilutions of the culture have been made in nutrient broth, and in all the experiments the cocci inoculated into each insulin sample (5 c.cm. quantities of insulin solution being used throughout) were contained in 25 c.mm. of the appropriate dilution. In each experiment the number of cocci inoculated was determined.

For the purpose of varying the reaction of the 5 c.cm. quantities of insulin solution under test, a sodium carbonate solution was prepared by dissolving 0·84 g. of sodium bicarbonate in 100 c.cm. of distilled water, the *solution being distributed, in* 5 c.cm. quantities, into test-tubes, which were then autoclaved. It was found that the addition of 0·2 c.cm. of this solution to 5 c.cm. of the insulin preparations used brought the reaction of the fluid to about pH 8.

RESULTS OF THREE EXPERIMENTS.

EXPT. 1.—From each of three of the insulin solutions, B1, B2, and L, duplicate 5 c.cm. quantities of insulin were measured out, and to one of each pair of tubes 0·2 c.cm. of the alkaline solution were added. The precipitate which first formed redissolved. To each of the six tubes 920 staphylococci were added, and the mixtures allowed to stand at room temperature for 48 hours. At the end of 24 hours, and again at the end of 48 hours, the number of viable cocci present in each tube, and the pH, were determined. The reaction of insulin solutions as prepared for use is between pH 3–4. The addition of 25 c.mm. of broth used for the inoculum *has a slight effect on the reaction,* the pH of all the solutions tested being about 4, or slightly more alkaline (Table I.).

TABLE I.

Preservative-free insulin.	Alkali solution added c.cm.	pH.	Number of cocci present after—	
			24 hours.	48 hours.
B1	Nil.		0	0
	0·2	8	0	0
B2	Nil.		0	0
	0·2	7·8	800	1200
L	Nil.		0	0
	0·2	7·8	14,000	Unc.

Unc. = uncountable.

EXPT. 2.—This was carried out in the same way as the previous experiment, except that: (1) The insulin-cocci mixtures were incubated at 37° C. for 24 hours and then allowed to stand at room temperature for a second 24 hours. (2) Gradually increasing quantities of the alkali solution were added to the 5 c.cm. samples of preservative-free insulins, B1 and L. The amount of material of preservative-free insulins B2 and B3 available was only sufficient for the single test quoted. (3) The number of cocci inoculated into each sample was 200 (Table II.).

EXPT. 3.—In this experiment the preservative-free insulin L and insulin L containing 0·3 per cent. tricresol were compared. Each tube was inoculated with 2200 cocci, and the mixtures were kept at room temperature throughout the 48 hours of the experiment (Table III.).

TABLE II.

Preservative-free insulin.	Volume of alkali solution added c.cm.	Appearance of solution.	pH.	Number of cocci present after—	
				24 hours at 37° C.	Second 24 hours at room temp.

I. = Preservative-free. II. = Containing 0·3 per cent. tricresol.

COMMENT.

Leyton and Poulton[1] raise the question as to whether an ordinary solution of insulin is a suitable *culture medium, and these experiments show that,* with the number of cocci used, such solutions are germicidal. In this respect the results are in complete agreement with those of Payne and Signy,[3] who showed that *B. coli* and *Staphylococcus aureus* failed to survive in insulin solutions of the usual acidity. The result is in accordance with expectation and with clinical experience; it is clear that, provided the normal acidity of insulin solutions is maintained, the danger of infection from casually introduced micro-organisms is not serious. It is shown in Experiment 3 that, even if the insulin solution becomes inadvertently neutralised, the presence of the usual proportion of phenolic preservative suffices to kill cocci which may be accidentally introduced.

If the normal acidity of an insulin solution containing no preservative is even slightly reduced, however, staphylococci are not killed by it, and under certain conditions considerable growth may occur. The range of reactions to the alkaline side of pH 6, in which multiplication was observed, differed in the case of different insulins, presumably on account of slight differences in their content of substances, other than insulin itself, which are capable of supporting bacterial growth. The widest range, as it happened, was observed in the case of the insulin which is usually issued without preservative. At a definitely higher reaction, higher with some samples than others, the solutions again became not merely incapable of supporting growth, but apparently coccicidal. For this action of the more alkaline insulins no explanation is offered at present, but it is hardly of practical interest for the present purpose. The important conclusion from these experiments is that an insulin solution may be made into a culture medium by a slight addition of alkali, if no preservative is present.

CONCLUSIONS.

(1) Insulin solutions, with the acidity commonly given to them (pH 3–4), have a germicidal action even when no added preservative is present. (2) A slight change in the reaction towards the alkaline side not only destroys this germicidal action, but converts the solution into a culture medium if no preservative is present. The usual proportion of phenolic preservative is still effectively germicidal under such conditions. (3) Opalescence or turbidity of the solution is not an adequate indication of such change of reaction. Solutions can be made sufficiently alkaline as to remain clear and still support the growth of cocci.

I record my indebtedness to my colleague, Capt. S. R. Douglas, F.R.S., for his help and advice during these experiments.

OBSERVATIONS ON THE PRODUCTION OF ANTIPOLIOMYELITIS SERUM IN HORSES

AND THE DISTRIBUTION OF THE ANTIBODY AMONG THE SERUM FRACTIONS.

BY R. W. FAIRBROTHER, M.D. MANCH.,

AND

W. T. J. MORGAN, M.SC., PH.D. LOND., F.I.C.

(From the Milbank Research Fund, the Bacteriological Department, Lister Institute, London; and the Serum Department of the Lister Institute, Elstree.)

WE have elsewhere recorded [1] the development of antiviral properties in the serum of one or two horses hyperimmunised by the intramuscular route with living potent poliomyelitis virus of monkey origin. The neutralisation tests with the serum revealed an activity comparable with that of human or monkey convalescent serum. The complete failure with the second horse raised again the question whether natural insusceptibility to infection with a particular virus necessarily precluded the production of antiviral bodies in response to hyperimmunisation, and it appeared desirable to attempt the immunisation of other horses.

Two additional horses were therefore given a course of intramuscular inoculations similar to that described in our earlier communications. In the hope of obtaining a potent antiviral serum in a shorter time an unfiltered emulsion of the virus-containing nervous tissue was used for the preliminary inoculations. The occurrence of severe anaphylactic-like reactions in the horses, however, forced us to continue the immunisation with the original filtered virus preparation. After both horses had received a total of 250 c.cm. of the filtered 10 per cent. virus emulsion a sample bleeding was taken, and tests were made with the serum samples to determine whether the serum had acquired any specific antiviral properties. The neutralisation tests were performed in the following manner: a mixture of the potent virus and the serum was allowed to stand in vitro at 37° for 1½ to 2 hours and left overnight at 4° C., after which time 0·5 c.cm. was injected intracerebrally under ether anæsthesia into *Macacus rhesus* monkeys.

RESULTS OF EXPERIMENTS.

The results indicated a marked difference in the protective power of the serum samples from the two horses; in one case, horse H3, this was very poor, whereas in the other horse, H4, the serum possessed marked antiviral properties.

	M497	† (4 „)

0 = animal remained quite well.
* Died T.B. nineteenth day.
† =paralysis and death, with the length of the incubation period in parentheses.

The serum of each of the horses collected before the inoculations commenced had not the slightest neutralising effect on the activity of the virus. After a rest period of six weeks further inoculations, amounting to 1100 c.cm. of the filtered 10 per cent. virus emulsion, were given to the horse H4. A large bleeding was then taken, and the separated serum tested for antiviral activity. The results of the neutralisation tests are shown in Table I. It is seen that the serum was extremely active, for 0·005 c.cm. completely neutralised the test dose of virus, which was estimated to contain at least 100 minimal infective doses.

In a previous communication [2] on the concentration of the protective substance in antipoliomyelitis serum it was shown that the protein which was precipitated at a relatively low concentration of ammonium sulphate was uniformly much more potent in antiviral action per unit weight of protein than that precipitated with higher concentrations of this salt. These experiments on the potency of the various protein fractions have been repeated by fractionating the potent immune serum from horse H4. The methods of preparing and testing the antiviral activity of the various fractions have already been described, and need not be repeated. The results are shown in Table II. Each animal received 0·2 c.cm. of a 5 per cent. virus emulsion, together with the amount of the protein fraction shown in the third column; in all cases the amount inoculated was 0·5 c.cm.

It will be seen that the protein which was thrown out of solution on dialysis possessed potent antiviral properties, since 0·017 mg. completely neutralised the test dose of virus. Both the pseudoglobulin and albumin fractions possessed some power to neutralise the virus; 0·23 and 0·49 mg., respectively, of these latter fractions completely neutralise the test dose.

TABLE II.—*Serum Fractions.*

Method of preparation.	Mg. protein.		Monkey.	Result.
	Per c.cm.	Per dose.		
Dialysis (euglobulin fraction) ..	3·5	0·087	M520	0
	3·5	0·043	M521	0
	3·5	0·017	M531	0
	3·5	0·0086	M537	† (6 days)
	3·5	0·0034	M538	† (9 „)

	46·5	0·58	M523	0
	46·5	0·23	M532	0
	46·5	0·115	M539	† (12 days)
	46·5	0·046	M540	† (7 „)
Ditto, 50 per cent.—saturation (albumin fraction) ..	35·5	0·89	M524	0
	35·5	0·49	M525	0
	35·5	0·18	M533	† (12 days)
Virus controls	Mixture inoculated. 0·2 c.cm. 5 per cent. virus emulsion, together with 0·3 c.cm. saline.		M515	† (5 days)
			M516	† (6 „)
			M541	† (4 „)

These results support the conclusions reached in our previous communication, that an antiviral preparation of high concentration can be obtained by collecting the so-called "euglobulin" fraction and dissolving it in saline. The results recorded in our previous paper indicated a general distribution of the antibody throughout the proteins of the particular serum examined, and the data yielded by the examination of the serum fractions of horse H4 show a similar general distribution of antibody (Table II.).

The statement made by Weyer, Park, and Banzhaf,[3] that there was a loss of antibody amounting to about 50 per cent. in their process of concentrating antipoliomyelitis serum, may be explained by the circumstance that the protective substance does not appear to be concentrated entirely in any one of the serum proteins.

COMMENT.

An antiviral serum of marked activity against the poliomyelitis virus has been produced by the intramuscular inoculation of the living virus in two horses. Two other animals completely failed to respond.

Weyer, Park, and Banzhaf,[3] and Schultz and Gebhardt,[4] in America, have also recently reported the successful immunisation of horses by the active virus, and it would therefore appear that the horse is a suitable animal for the production of an antipoliomyelitis serum for therapeutic use, though at present we have no means of ascertaining without trial whether any one horse is likely to respond.

This serum has been used in a few cases of poliomyelitis in this country, but it has not proved possible, so far, to draw any conclusion with regard to its efficacy. It is well known that the variable nature of the disease makes it difficult to assess the value of specific forms of treatment in the prevention of paralysis, and it is generally believed that specific treatment with convalescent serum is likely to be of small value when given after paralysis has appeared. It may be expected, however, that the renewed interest aroused by the production of antiviral serum in large animals may lead to much-needed information on these debated points.

CLINICAL AND LABORATORY NOTES

THE CREASES ON THE MINIMAL DIGIT IN MONGOLISM.

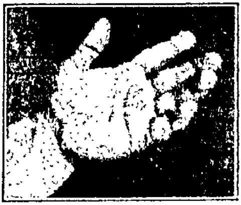
By L. S. PENROSE, M.D. CAMB.,

RESEARCH MEDICAL OFFICER, ROYAL EASTERN COUNTIES INSTITUTION FOR MENTAL DEFECTIVES.

SOME of the dispute concerning the ætiology of mongolism arises from doubt concerning the precise physical signs which are, or are not, characteristic of the condition. Clear-cut signs which are easily recognised are therefore of importance, and the morphological peculiarities of the hand are physical signs which have these qualities. The transverse simian crease on the palm of the hand is, however, frequently seen in normal persons. The incurving minimal digit is a sign with many degrees of intensity and is present in a variety of different conditions, while a short minimal digit is characteristic of all so-called degenerate types of hand.

A simple and very definite abnormality found almost exclusively among aments of the mongolian type, which seems not to have been hitherto described, is the replacing of the usual three creases on the minimal digit of the hand by two creases only, so that the markings on this finger resemble those on the thumb, although the correct number of phalanges is present.

The little finger has normally a distal single crease nearly opposite the distal interphalangeal joint, a medial double crease just below the proximal interphalangeal joint, and a basal digital line which is complex.[1] In the anomaly described here a new crease, usually double in character, takes the place of the distal and medial creases, and it lies between the distal and proximal interphalangeal joints.



The accompanying photograph is of the left hand of a female mongolian defective, aged 40. The unusual line on the minimal digit is clearly marked. An elderly patient was chosen purposely, in order to show that age does not obscure the clearness of this sign. The minimal digit of the patient's right hand has the usual creases, although it does not differ from its fellow in length or in the configuration of the complex basal line. The transverse simian crease is not present on either hand in this case.

---

[1] Jones, F. Wood: The Principles of Anatomy as seen in the Hand. London, 1920, pp. 67–68.

It is interesting to compare the incidence of this latter peculiarity with that of the anomalous creasing of the minimal digit. In a series of 60 mongolian defectives, 44 of whom are under the care of the Royal Eastern Counties Institution, the absence of one of the creases of the little finger was observed in 16 cases. In 8 of these the abnormality was present on one hand only. The transverse palmar line occurred in 27 cases, and was present on one hand only in 10 of these. The latter anomaly seems therefore to be about twice as frequent as the former.

These two peculiarities are often met with in association. They are to be seen together in the photograph by Dr. T. Brushfield, reproduced in Tredgold's text-book.[2] In the series of patients referred to above, both anomalies were present on both hands in three cases, and in five others they were simultaneously present unilaterally. The number of associations of these two uncommon peculiarities here is greater than that which would be expected if their occurrence together were merely a chance affair. This fact suggests that the causes of the two peculiarities are related to one another.

I am indebted to Dr. F. D. Turner for permission to publish these notes, and to the Medical Research Council and the Darwin Trust for financial assistance.

WAX BATH TREATMENT.

BY H. W. HALES, M.D. CAMB.

THE full-length wax bath was first employed in France about 20 years ago, but it is only during recent years that it has attained the recognition which it deserves. The employment of paraffin for burns and as a method of administering heat locally to joints has, of course, been widely known for a much longer period.

The technique of full-length baths consists in applying a large quantity of wax in a liquid state to the whole of the body at a temperature of 120–130° F., depending on the skin sensitiveness of the patient. The wax rapidly solidifies when it touches the skin, and at the same time contracts. Heat-loss is reduced to a minimum by applying further layers of wax on the top of the first. The whole wax coat is then still further insulated by folding over and approximating the edges of the paper on which the patient lies, and one or two layers of waterproof sheeting are also folded over the patient. In cold weather a blanket can be added. The first treatment usually only comprises the legs and thighs; the second goes as high up as the umbilicus; and the third or fourth embraces the whole body up to the neck except one arm. The total skin surfaces finally covered depends on the reaction observed during the first two or three treatments. Profuse sweating occurs in from 2 to 10 minutes both on the free skin surfaces and under the wax. After a period varying from 15 to 30 minutes the wax is removed and the patient massaged with eau-de-Cologne as a grease solvent. He then rests for 15 to 30 minutes in a cool room, and can either have a cold or tepid spray or bath, or else dress. The oral and rectal temperatures and pulse are taken before treatment, and the oral temperature and pulse at frequent intervals during the treatment. At first the pulse rises to 90–96, a little out of proportion to the temperature (if a normal ratio of 90 pulse to 99 temperature and 100 pulse to 100 temperature, and so on, is assumed), but as soon as free perspiration has been established the temperature rises and the pulse falls and they attain their normal ratio. The blood pressure falls slightly. The temperature rises from 1 to 4 degrees, depending on the personal idiosyncrasy of the patient and the amount and temperature of the wax used.

The hydrogen-ion concentration of the sweat varies with its dilution, and the parts of the body. The baths are given daily or alternate days until the sweat pH is alkaline on its first appearing, and the interval between the baths is only increased when the blood pressure is low, or when the activities or peculiarities of the patient prevent daily treatment.

It has been claimed that one of the most marked features of this treatment is the absence of skin erythema indicating that the wax has a constricting effect which prevents cutaneous vasodilatation, but I have not observed this.

Contrary to expectation, after the first few minutes there is no sense of constriction from the solidified wax, probably because its elasticity allows for stretching as the pores exude sweat. For this reason it does not seem possible to subscribe to the theory that there is less removal of blood from vital internal organs to the periphery in this than in any other form of pyretic treatment.

The physics of this treatment are open to speculation both as regards the possible effect of the initial contraction of wax, and the curious fact that owing to its super-cooling wax becomes hotter on solidifying only to cool very slowly; but here one has to consider how the temperature of the wax immediately against the body is modified by that of the skin and sweat. In this treatment one has a very perfect form of increased heat administration to the skin and elimination of heat loss to a minimum. The weight of wax is also interesting, being lighter than water and heavier than foam when compared with the somewhat similar idea embodied in Transkutan and foam-bath therapy. All these pyretic treatments can be conveniently classified according to the weight of the agent used, beginning with Pistany mud and descending through Droitwich brine, Transkutan, wax, foam, Percy Wilde pyretic couch, to radiant heat, infra-red baths, and four-pole pyretic diathermy which have no weight at all.

It is not proposed in this short communication to discuss the relationships and differences of these various treatments, but there can be no doubt that in wax we possess a valuable therapeutic agent which in certain cases works better than any other, and in a few is the only method which will give results. It must be emphasised, however, that it produces marked reactions and that indiscriminate administration by unqualified persons who are not under medical supervision may do more harm than good.

ENLARGEMENT OF CHELMSFORD HOSPITAL.—Extensions of this institution, costing £32,000, were opened last week without formality. They include a ward each for men, children, and casualties, and the total accommodation has been brought up to 114 beds. Other additions are a new out-patients' department, dispensary, eye clinic, minor theatre, consulting rooms, private ward block, and an administrative block; the adjoining nurses' home has also been enlarged. A sum of £12,000 remains to be raised.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

The second session of this section was devoted to the causation and treatment of

Menorrhagias not due to Uterine Disease.

Mr. A. S. Parkes, speaking on the physiological aspects of menstruation, said that in lower mammals the ovarian cycle consisted of two phases, the follicular or œstral phase, in which the Graafian follicle matured and ruptured, and the luteal phase, in which the corpus luteum developed. In the first, only minor changes occurred in the uterus, but in the luteal phase the uterus was prepared by an increase of its physiological sensitiveness, with or without proliferation of the endometrium, for reception of the fertilised ovum. If pregnancy did not take place the prepared endometrium retrogressed, the severity of the process of destruction varying in different species and the resulting hæmorrhage also varying in amount. In certain animals, however—e.g., the dog—hæmorrhage into the uterine lumen was found in the immediate pre-ovulation phase, the hæmorrhage then indeed being more pronounced than that at the end of the luteal (pseudo-pregnant) period, while it might continue then for as much as ten days. In attempting to interpret the human menstrual cycle in the light of the facts pertaining to lower animals two theories had to be considered: (1) that menstruation is a pre-ovulation phenomenon; (2) that it is an exaggerated homologue of the pseudo-pregnant breakdown found in many of the lower mammals. The weight of evidence was in favour of the second view. On this view alone, however, menstruation depended on the preliminary development of the corpus luteum, and it was now known that menstruation could occur in absence of ovulation. Since it was known that the œstral changes of the accessory organs of lower animals might take place without a morphological cycle in the ovary, this fact of course favoured the view that the breakdown was pro-œstral in nature.

Much assistance could, however, be obtained from the lower primates. In the baboon the follicular phase, during which the follicle developed, was characterised by the appearance of an enormous swelling of the vulva, which subsided after ovulation. About ten days later menstruation of the usual type appeared. The start of the cycle at puberty was marked by the appearance of the external swelling, and so there could be no doubt that in this mammal the follicular phase began and passed away some time before the onset of menstruation. It was thus possible to say that menstruation was not a straightforward pro-œstral phenomenon. On the other hand, when the monkey failed to ovulate, the same external signs of the follicular phase appeared, followed by menstruation as usual but with no premenstrual development of the endometrium; this occurred only in presence of a corpus luteum. The menstruation there and the necrosis leading to it were independent of atrophy of the corpus luteum. From the point of view of treatment of menstrual irregularities it was of the first importance to discover what the factor was that led to necrosis of the endometrium, and some fresh evidence had lately become available. Some years ago Allen showed that injection of œstrin into ovariectomised monkeys led to menstruation, and recently Hartman had shown that this effect was entirely lacking if the animal were hypophysectomised. It was thus necessary to assume that Allen's results were due to activation of the pituitary by œstrin, and that the substance causing necrosis of the endometrium was hypophyseal in origin.

CAUSATION, CLINICAL FEATURES, AND TREATMENT.

Dr. James Young said that the group of uterine hæmorrhages under discussion included the majority of cases of bleeding uteri, and the bulk of those cases which in the past had been described by such terms as chronic endometritis and metritis, fibrosis uteri, and subinvolution. He described the pathological and clinical features of metropathia hæmorrhagica (Schroeder's disease), the main symptom of which was metrorrhagia or irregular continued bleeding, and which characteristically occurred between 40 and 50. The endometrium showed a diffuse hyperplasia, often polypoidal, with cystic dilatation of glands and extensive areas of necrosis, while the ovaries exhibited characteristic changes—namely, cystic degeneration of follicles, and failure of formation of corpora lutea. Polymenorrhœa or too frequent menstruation was another common type of dysfunctional bleeding often accompanied by prolongation and quantitative increase in the flow. The shortened menstrual rhythm was associated with a corresponding shortening of the follicular cycle in the ovary, without any very constant changes in the endometrium.

Dysfunctional menorrhagia—excessive or prolonged flow at normal intervals—might also be due to ovarian aberration, and accompanying endometrial changes though not constant were often present. Schroeder, however, believed the chief cause to be hyperæmic states in the pelvis and inadequate contractility of the uterine muscle. Post-menopausal bleeding was not infrequently found in the absence of any gross uterine disease, and it might be that a temporary rejuvenescence of the ovary was responsible, or where the bleeding was excessive a structural degeneration in dormant follicles. In 72 cases of post-menopausal hæmorrhage Dr. Young had found 11 in which all factors other than ovarian had been excluded. Of 86 consecutive hospital cases in which the well-known causes of uterine bleeding—such as tumours and malignancy—had been excluded, 13 were cases of menorrhagia, 28 of polymenorrhœa, 39 of arrhythmic and continuous bleeding, and 6 of post-menopausal bleeding. Dr. Young pointed out the frequent association between cervicitis and menstrual irregularity and excess. In a consecutive series of 177 cases in which chronic cervicitis was the sole recognisable pelvic lesion, either menorrhagia or polymenorrhœa was present in 63 per cent. Such cases were often cured by treatment directed solely to the cervix. These findings were in keeping with the view that the cervical disease provoked the bleeding through the medium of an ovarian hormone. Another important factor was general organic disease which was present in at least 29 out of the 86 cases, while the important part played by infection was indicated by the fact that 33 of the 86 cases dated from childbirth or abortion.

As regards diagnosis, Dr. Young stressed the importance of eliminating by complete investigation such causes of bleeding as cancer and fibroids. When physical examination failed to provide an adequate explanation of the bleeding a curettage should be carried out. Bleeding in the 'teens was the only exception to this rule, and in such cases treatment might usually be begun forthwith on a clinical diagnosis.

In treatment ovarian extracts had been disappointing in his hands, though with Sistomensin cure was reported in 5 out of 23 cases, while 5 others were much improved. Relief, immediate and permanent, might follow curettage. Of his 86 cases, in all of which curettage was done, cure followed in 11, but in 4 of these a chronically inflamed cervix was cauterised at the same time. If curettage failed the choice lay between hysterectomy, and radium or X ray sterilisation.

GENERAL DISORDERS.

Dr. H. **Gardiner-Hill** discussed the problems of menorrhagia in relation to general medicine. While menorrhagia might be a symptom in a number of different diseases, in some it played such a subsidiary part in the clinical picture that it was unlikely to come under the notice of the gynæcologist—e.g., the menorrhagias sometimes found in chronic cardiac failure. In other general diseases, however, menorrhagia might be one of the primary symptoms. He divided the cases into three main groups: (1) circulatory disorders; (2) the hæmorrhagic diathesis; (3) ductless gland dystrophies. Under the first heading he included active and passive congestion. Menorrhagias due to passive congestion rarely came first to the gynæcologist. Usually the general symptoms were pronounced. Active congestion, especially that due to hypertension, was an occasional cause of obscure menorrhagia. The general symptoms were often slight. The menorrhagia usually improved as a result of measures which lowered the blood pressure. He thought some of the menorrhagias of the climacteric where cardiovascular disease was present and the blood pressure high might also be accounted for on this basis. The second group, the hæmorrhagic diathesis, was somewhat ill-defined. These cases were not common, though he had seen two or three examples of a tendency to thrombocytopenia. A history was usually obtained of a tendency to bleed easily. There were often recurrent attacks from childhood of epistaxis, gastric or intestinal hæmorrhage, or prolonged bleeding after slight operations. In these cases the menorrhagia usually dated back to puberty and there was a deficiency of blood platelets. In the third group he would include disturbances in the internal secretion of the ovaries, the thyroid, and possibly the pituitary. Puberty menorrhagia was often associated with precocious development of the secondary sex characters and a peculiar type of skeleton, the lower extremities being abnormally short in proportion to the trunk, owing to early closure of the epiphyses. This was due to hyperovarianism. In primary ovarian deficiency the opposite condition occurred (eunuchoidism) and there was primary amenorrhœa. He thought that skeletal measurements and radiography should form a routine part of the examination in such cases. Thyroid deficiency was a common cause of menorrhagia, especially at puberty or the climacteric. Puberty cases were often associated with simple goitre, those at the climacteric with myxœdema. Myxœdema was particularly liable to develop after the climacteric. When, however, it developed before that time menstruation, if affected at all, usually showed a tendency to menorrhagia. In the last ten years he had seen over 100 cases of myxœdema, 17 of whom had a history of severe pelvic operations for menorrhagia when there had been no apparent pelvic cause. The patients subsequently developed typical myxœdema, and it seemed most likely to him that the original menorrhagia had been one of the first symptoms. Treatment with thyroid was often successful. He had not found hyperthyroidism at all a common cause of menorrhagia. In Graves's disease menstruation was often unaffected; in many cases amenorrhœa was present during the active stages of the disease. The rôle of the pituitary in relation to menorrhagia was as yet undecided, though recent work had shown that the anterior lobe was intimately connected with ovarian development.

CAUSES AND CURES.

Dr. S. **Zuckerman** said that theories of the cause of menstruation were of two kinds—those which attributed it to the removal and those which regarded it as due to the addition of some influence. To the first group belongs the view that it is due to the removal of the effect either of the corpus luteum or of the follicular hormone. The corpus luteum hypothesis had been discredited, since menstruation took place in cycles in which ovulation had not occurred. The œstrin hypothesis rested on indirect evidence. To the second group belonged Hartman's theory that menstruation was due directly to the activity of a substance elaborated by the anterior lobe of the pituitary. This hypothesis was the most hopeful, for one thing since it suggested such ready experimental methods for its verification.

Mr. St. **George Wilson** reviewed 92 cases treated in the last nine years. Curettage was, he thought, essential in patients of 40 years and over, but was not likely to cure. Hysterectomy was rarely necessary, but if it was done the vaginal route was preferable. Radium was ideal in doses of 200–2500 mg.-hours, and the younger the patient the smaller should be the dose. X rays were less valuable in hospital patients who wished to be cured soon, and who were apt to be discouraged if immediate results were not obtained.

Dr. W. **Langmuir Watt** said that for temporary sterilisation by X rays 27 per cent. (4 radiations of 15 minutes each) and for permanent sterilisation 35 per cent. (4 of 18 to 20 minutes each) of a skin erythema dose was required. For the former slightly larger doses were required in patients under 30 than over. With the same dosage patients under 30 would have amenorrhœa for about a year, but over 30 for about 18 months. There was usually one period after sterilisation which might be profuse. Polymenorrhagia might be associated with hypofunction of the thyroid, and a small radiation to this gland might restore normal periodicity, and this in young women might be combined with a small radiation to the spleen. If it failed, then a temporary sterilisation of only one ovary should be carried out, and cured in 50 per cent. of cases. If this failed the other ovary could be temporarily sterilised. Sterilisation by modern apparatus was simple, safe, and avoided all exposure.

Prof. J. B. **Dawson** said that conditions of the corpus uteri that caused menorrhagia were commonly associated with cervical lesions. These might lead to hormonal disturbances consequent upon inflammatory thickening of the ovarian cortex following the cervical infection. In the specimen shown by Dr. Young (as an example of metropathia hæmorrhagica) the cervix was cystic and hypertrophied—a post-infective lesion.

Mr. ERIC STACEY quoted the well-known experiment in which during laparotomy a ripe follicle was punctured and menstruation followed in 30–36 hours. This showed that some process was initiated by which the necrosis of the endometrium was brought about—possibly the liberation of a hormone which produced activity of the anterior pituitary lobe. So far nobody had suggested what stimulated production of this anterior lobe hormone. Collip, of Toronto, had recently isolated a hormone from the ovary which had a similar effect to the injection of the anterior lobe hormone called emmenine. This hormone was present in the ovary in addition to the œstrin and corpus luteum hormones. It was not improbable that many of these cases of menorrhagia and epimenorrhœa were brought about by over-production of a pro-œstrus hormone. He had often noticed that a condition in the ovaries of sclerosis with over-production of follicles was present in conditions associated with pelvic congestion from whatever cause and productive of symptoms such as these under discussion.

The PRESIDENT (Mr. EARDLEY HOLLAND) said that every case of menorrhagia should have a full medical investigation, including a platelet count. He doubted if high blood pressure could by itself cause menorrhagia. X rays appeared to have this advantage over radium, that by it one could cause temporary sterilisation, while with radium this was difficult.

SECTION OF ORTHOPÆDICS.

AT the first session of this section Mr. A. S. BLUNDELL BANKART, the President, took the chair, and a discussion on the diagnosis and treatment of

Common Injuries of the Knee-joint

was opened by Mr. NAUGHTON DUNN. With increasing experience of injuries of the knee-joint, he said, he became more and more convinced that exact diagnosis of the injury was often impossible before operation. Describing the normal anatomy, he pointed out that as the joint connected the two longest bones in the body, it was subject to enormous leverage, and had therefore been provided with powerful muscles and with very strong ligaments which limited movements in all directions except flexion. Rotation at this joint was only possible in the flexed position, which doubtless accounted for the fact that in his experience strain of the flexed knee was responsible for the great majority of injuries to the intra-articular cartilages. Although anatomists described 12 bursæ in connexion with the knee, surgeons only took note of four as a source of symptoms, though possibly affections of some more deeply seated might be the cause of some lesions whose diagnosis was obscure. Articular cartilage was avascular, and this meant that it had little power of repair. The synovia not only oiled the joint, but was also richly supplied with sensory nerves, which made it a great source of pain. In connexion with swellings of the joint, it should not be forgotten that œdema of the infra-patellar pad of fat might closely simulate effusion into the joint itself.

Mr. Dunn showed a table analysing the lesions found in 522 consecutive cases of injury to the knee-joint, of which 179 were diagnosed as lesions of the internal semilunar cartilages (139 being confirmed by operation) and 71 of the external cartilages (46 confirmed by operation). Practically all subsequent speakers commented on this proportion of external cartilage injuries as most abnormally high, and Mr. Dunn in his reply was unable to account for it, but said he was sure it was not due to any clerical error, for even in the records kept personally by himself it still appeared. In the series lesions of the internal lateral ligament accounted for 34 cases and loose bodies for another 34, while each remaining group, such as crucial ligament injuries, articular fractures, Osgood-Schlatter disease, and direct infections, each only accounted for a small number. Many indefinite cases responded to manipulative treatment, which suggested that they were due to adhesions, and probably another considerable group were due to subacute, infective arthritis.

Mr. Dunn thought that one might safely make a diagnosis of damage to an intra-articular cartilage if there was a history of recurrent locking with pain and tenderness limited to the attachments of the cartilage, and provided that the joint regained normal function between the attacks. The types of cartilage injury found at operation were: tears of the anterior end; tears of the posterior part; and bucket-handle tears. Several cases were described in which the cartilage appeared normal at operation, but its removal cured the symptoms. In other cases, tenderness and pain referred to the inner side of the joint were found associated with a lesion of the external cartilage only, while simultaneous lesions of both cartilages did occur; accordingly when a typical history had led to exploration of the inner side of the joint and a normal cartilage was found, it was advisable to explore the outer side of the joint also. Mr. Dunn also referred to the difficulty presented by a slipping patella, whose history might simulate cartilage injury, while the actual dislocation was seldom witnessed by the medical attendant. Such cases were best tested in the gymnasium. Under the anæsthetic one should note whether the patella on the affected side had more lateral mobility than on the other side. Loose bodies also presented difficulties in diagnosis, but the locking in such cases was apt to be very temporary. Radiograms were shown of a case in which a piece of metal had travelled in the course of months from the inter-condylar region, where it caused intermittent symptoms, to the lower part of the popliteal space. A specimen was shown of a loose body detached from the back of the patella by a direct blow on the front; in such cases early operation was advised, as the fragment was likely to cause increasing damage to the articular cartilage. Mr. Dunn found that damage to the internal lateral ligament was caused by force applied to the extended knee, the opposite to that affecting the internal cartilage; tears were seldom complete, and many recovered entirely without operation. Where damage to both ligament and cartilage was suspected, he advised waiting till the ligament had healed before opening the joint for removal of the cartilage. For fractures of the tibial spine he recommended gradual extension of the joint and splintage before operation; for crucial ligament injuries, also, he advised conservative treatment as far as possible, seeing that he found that operative repair had not been able to restore the joint to normal. This was the reverse of the results of operation on cartilages, for in a series of 65 professional footballers a very high percentage had been able to return to this most strenuous of games, even after removal of both cartilages. Regarding the technique of operation for internal cartilages, he advised a small internal incision, nearly vertical, so as to avoid the patellar branch of the internal saphenous nerve, which in his series of cases had seven times resulted in a painful neuroma, demanding subsequent operation.

In connexion with injuries of the extensor apparatus, he suggested that the greater was the flexion of the knee at the time of the accident, the higher would the damage occur—e.g., tears of the ligamentum patellæ occurred with an almost extended knee. He showed among others radiograms of a bipartite patella, which might easily be misdiagnosed as a fracture.

DISCUSSION.

Sir ROBERT JONES agreed with Mr. Dunn that in many internal derangements of the knee diagnosis of the exact lesion was impossible, while cases of classical cartilage symptoms might prove at operation to be something quite different. He thought it was usually possible to differentiate between injury to an internal and to an external cartilage, though locking was common to both; usually in the *first attack* the pain was correctly localised, though in the later attacks of recurrent cases it might be felt on the wrong side of the joint, so that he considered a careful history of great importance. It was rather the sudden, complete *unlocking* from flexion that was so diagnostic, and if flexion only yielded gradually, he would not consider it a case of cartilage injury at all. Clicking was more common with external than internal cartilage damage. Pain on abduction and adduction suggested injury to a ligament. In view of the fact that many injured cartilages only gave one attack of symptoms, Sir Robert advised reduction by manipulation in the first instance and reminded his hearers that reduction was never complete unless it gave full extension of the joint and immediate relief of discomfort; it was no good trying to persuade oneself or the patient that the cartilage had been reduced unless these conditions were fulfilled. He treated cases by two or three weeks of full extension during walking and after this crooked the inner side of heel of the boot, also prescribing inward rotation of the limb during running and walking. The actual technique of reduction of a cartilage was simple—i.e., the knee should be acutely flexed, rotated in and out and extended. In an unreduced case of many weeks' standing, the knee should in addition be moved in all directions to break adhesions. For this purpose the knee should first be fully flexed, then fully extended, and finally flexed with the thigh hyper-extended, since this tightened all the structures on the front of the thigh; from the flexed position the knee should be extended, during which act the tibia should be rotated 10 or 15 times. Finally, the knee should be flexed while the surgeon's forearm was placed in the popliteal space and used as a lever.

In considering the treatment of ruptured crucials, one should not forget that excellent recoveries occurred with conservative treatment after complete dislocation of the knee, where every ligament must have been torn. A tibial spine displaced forward so as to prevent complete extension of the knee should be removed. Operation for torn cartilage was desirable in every recurrent case, and essential if effusion kept occurring in a patient who wanted to take part in athletics. Sir Robert agreed with Mr. Dunn that even if a cartilage appeared normal at operation it should be removed completely, for certain posterior lesions could only be discovered in the process of removing the cartilage. For loose bodies he advised either syringing, or else anchoring the body by a needle before opening the joint.

Mr. H. A. T. FAIRBANK pointed out that the extreme wasting of the quadriceps in cases of knee injury could not be due to fatigue in those cases where there was no spasm, but it must be of the nature of a reflex inhibition. He suggested as sources of obscure pain lesions of the popliteus tendon, the ilio-tibial band, and the insertion of the semi-membranosus. To bring the posterior end of a cartilage into view at operation he advised a blunt hook. He recommended that all complete ligament tears, not mere strains, should be treated by early suture. He thought that lesions of articular cartilage were less uncommon than is generally supposed, and also that fractures of the tibial spine were of two types: (1) a shearing by the internal condyle of the femur, which gave only slight displacement and did not need operation; (2) tear of an anterior strip by hyper-extension, which required suture or pegging.

Dr. W. H. W. ATTLEE gave an account of the lesions found in schoolboys, the commonest being effusion, associated with rapid atrophy of the thigh muscles, while epiphysial injuries came next in frequency, and meniscus injuries third. The effusion soon cleared up if a few days' rest in bed were immediately followed by regular exercise on a bicycle or at rowing. He thought prolonged rest was far too often prescribed, while direct massage to the joint delayed recovery. The common lesion associated with pain in the tibial tubercle occurred chiefly in the football season and cleared up when football was stopped—e.g., in the running season. Painful heels then took its place. Radiographic diagnosis of lesions of the tibial tubercle was fallacious, as demonstrated by various prints, some showing peculiarities in the absence of symptoms, others the reverse. In any case it was essential to radiograph both sides for comparison. Dr. Attlee pleaded for greater confidence in the reparative power of Nature.

Mr. ROWLEY BRISTOW emphasised the importance of early exercise after operation for the removal of a cartilage. His practice was to make the patient lift the limb off the bed a few days later; he began faradism on the sixth day and got the patient up on the tenth, but continued treatment till the full range of joint and muscle power had returned.

Mr. T. P. MCMURRAY asked that the term "locking" should be abandoned as misleading, for it was the sudden unlocking that was characteristic. He disapproved of a pessimistic attitude in regard to diagnosis, and demanded more accuracy, which he said could be attained by his method of examination—i.e., flexing the knee completely, then, as it is extended, rotating it at each angle, which gives a localising pain and usually a click also.

Mr. ROBERT OLLERENSHAW showed interesting radiograms of a complete knee dislocation with excellent function after reduction. He pleaded for rest and fixation in plaster for about six weeks in the early stages of Osgood-Schlatter disease. In regard to the level of injuries to the extensor apparatus, he thought age determined it, tears of the quadriceps tendon occurring in the elderly.

Mr. R. C. ELMSLIE did not approve of resting a knee after reduction of a displaced cartilage, and quoted a case of the Oxford boat captain who rowed a trial course 24 hours after it. He advised a compression bandage, to be kept on during faradism to the quadriceps. He diagnosed patellar dislocations by noting that in the last stage of active extension the patella moved outward more on that side.

Mr. LAMING EVANS laid stress on complete removal of a cartilage, which could be done through the usual incision by rotating the tibia outward in flexion.

Mr. McCrae Aitken highly approved of cycling and rowing in after-treatment, as they provided a physiological push, without grinding of the joint surfaces.

Mr. Rocyn Jones thought that the results of cartilage operations depended on the age of the patient and on the condition of the quadriceps. He held that the relative frequency of external cartilage lesions in the young, even at 4 years old, was due to congenital abnormalities; he had removed one which was disc-shaped.

SECTION OF PUBLIC HEALTH.

At the meeting of this section, held on July 23rd, the chair was taken by Sir George Buchanan, the President, and a paper on public health problems attendant on

Air Travel

was read by Dr. A. Massey. The contingencies introduced by aerial navigation were, he said: (1) that journeys could be accomplished within the incubation periods of the major infectious diseases; (2) illicit or forced landings might result in importation of infection at places other than authorised air-ports equipped to deal with it; (3) infected mosquitoes could be brought from fever zones alive; and (4) aircraft might let fall refuse matter capable of conveying infection. Plague, cholera, yellow fever, small-pox, and typhus all had incubation periods longer than the corresponding period of air travel from infected countries. Apparently healthy passengers from these places must be kept under surveillance until the incubation periods had expired, unless they were known to be immune. It was essential that passengers should be free from manifest infection on embarkation and that aircraft should be cleaned, deratised, and de-insectised before departure. It was possible to import mosquitoes infected with yellow fever, but they would probably perish with the first cold weather. Special precautions, however, would need to be taken at air-ports of departure to ensure freedom of aircraft from mosquitoes. Rat harbourage in aeroplanes was limited, but by no means unknown. Vermin were unlikely to be carried by passengers who could afford air transport. Aircraft, unlike ships, were not limited to natural ports, and thus the importation of infection was more likely to occur. Illicit landings should be suppressed, and forced landings made notifiable to the nearest customs and sanitary air-port. Stringent international rules would be necessary to prohibit the voidance of refuse from aircraft over land. A conservancy system was essential for long-distance aeroplanes. The heating and ventilation of long-distance passenger aircraft presented peculiar difficulties. Selected aerodromes should be recognised as customs and sanitary air-ports for international travel, and to these would be attached medical and sanitary personnel.

The President said that presumably necessary sanitary precautions would be made available at ordinary customs aerodromes, but that special aerodromes would be set apart for more complex procedures, such as deratisation. Many unnecessary limitations in the past had been placed on shipping—for instance, the "bill of health" and "observation." It was important that these should not be imposed on aircraft. The requirements needed careful thinking out in advance. Air travel introduced new risks, especially from diseases of short incubation period.

Sir Malcolm Watson said that the biggest sanitary problem in the world at the moment was the probability of yellow fever getting from the West Coast of Africa to the East Coast, where it would certainly not be diagnosed, and whence it would certainly spread to Asia. He recalled the elaborate efforts necessary to eradicate the fever from Panama. Shipping would take it to Bombay and Colombo, where anti-mosquito work was in an extremely bad condition. The results—with a death-rate of 75 per cent.—would be appalling, and trade with the East would be paralysed. Civilisation would be shaken to the ground. The first step was to prevent aeroplanes from carrying the disease across Africa.

The President said that the international agreement against the transmission of yellow fever would be based on precautions against embarkation in the endemic areas.

Dr. Massey, replying to questions, said that he had no authentic evidence that rabies had been brought into the country by smuggled dogs, but it was certainly a disease that might be spread by aircraft.

Isolation Hospitals.

Dr. E. H. R. Harries read a paper on the Function of the Isolation Hospital in Modern Practice. He said that the isolation of the infectious sick involved also treatment, and should include teaching and research. Isolation of early cases was of great value in epidemic disease, but of very little in endemic disease, which could only be rationally controlled by active immunisation of susceptibles. Nevertheless, the isolation hospital played an important part in the care of patients under special circumstances, and its existence was justified. Its available accommodation was not, however, always used to the best possible advantage. It was unique in having no casualty or out-patient department or convalescent home. Cases were admitted direct from the general practitioner, and the inevitable result was the unnecessary isolation of large numbers of adults and children, especially in diphtheria epidemics, with resulting pressure on the accommodation. The value of the swab in diagnosis was as much over-estimated in diphtheria as the value of a timely dose of antitoxin on suspicion was under-estimated. Patients were also kept through convalescence, partly from a quite disproportionate fear of infectiousness in that period. Some infections could not be adequately treated outside an institution, but rubella, chicken-pox, and many cases of scarlet fever could be treated at home. The public needed, however, to be more impressed with the gravity of whooping-cough and measles. Treatment of fevers had become more complex, and demanded team-work and as complete a technique and equipment as the treatment of any other disease.

The fever hospitals had a monopoly of the material necessary for the clinical teaching of fevers and, with one exception, these institutions were controlled by public health authorities. The ex-resident medical officers formed but an infinitesimal part of the whole profession, yet these were the only doctors who had adequate clinical experience of fevers. By some means the material in these hospitals should be made available for undergraduate and post-graduate study. The student might clerk for a period in a fever hospital and the young pediatrist be attached for a term to the staff. The contributions of the fever hospitals to original research had been very small indeed; there was no stimulus, no official recognition, and usually no equipment for research. The continental and American output, on the other hand, was high. The fever hospital could make a valuable contribution to the study of early rheumatism. Suitable medical officers should be set free from routine duties and encouraged to research, and applicants for research fellowships should consider the rich field offered by the fever hospital.

The PRESIDENT said that he thought there had never been a time of greater need for stock-taking in public health.

Dr. J. D. ROLLESTON agreed that large numbers of cases were sent to fever hospitals wrongly diagnosed and entirely free from disease, and that hospitalisation of scarlet fever was largely unnecessary and only carried out for the convenience of householders and private practitioners. Certain groups of cases, however, required hospital treatment—severe cases, and cases occurring in public places of business. The isolation of measles and whooping-cough had been undertaken to save life, not with the hope of eradicating the disease. Attendance at a fever hospital ought to take place at an early stage of the student's career; he would learn there matter which would stand him in good stead in any branch of practice, and would bring him into touch with at least half a dozen branches of medicine. More research was being undertaken than Dr. Harries had suggested. A further stimulus might be applied by insisting that officers intending to remain in the service should take their M.D. and M.R.C.P.

Dr. R. A. O'BRIEN suggested an unofficial inquiry into the responsibility for diphtheria deaths due to failure to receive early antitoxin. The percentage of misdiagnosed cases was striking, and might well be related to the present method of teaching. Fevers might well be treated in annexes to general teaching hospitals. He was less optimistic about research than Dr. Rolleston. In London there was a real attempt to produce an urgent spirit of clinical and pathological inquiry, but this was not found in the provinces. A review of the literature would not show a large contribution from this country. Every general hospital had its pathologist, but there were 30,000 fever beds outside London without a single pathologist. He suggested that new fever hospitals might be built in close touch with general teaching hospitals.

Dr. W. E. PORTER pleaded the difficulties of the general practitioner called on to treat scarlet fever in the home. If one child were treated at home the whole family had to stay away from work or school.

Dr. D. S. SUTHERLAND said he had been impressed by the different amount of teaching given to medical students on this subject; in many cases it was very inadequate, even for the D.P.H. course. Classes were often much too large. Possibly some of the old poor-law institutions could take over fever work, concentrating the work of a number of small institutions where both treatment and training for nurses were inadequate. Concentration near a general teaching hospital would aid both education and research.

Dr. ARTHUR HAWLEY declared that the teaching of medical students was quite inadequate. Dr. L. P. LOCKHART suggested that the system of clinical assistantships should be extended to fever hospitals. Dr. H. KELSON cordially supported the idea of centralisation, with pathological assistance on the spot. It was the duty of the practitioner to notify cases that were at all doubtful, and accurate diagnosis was the duty of the public health service. He thought that early discharge had gone too far; marked secondary results might follow mild cases of scarlet fever, and the period of rest was of value. He urged the importance of research. Dr. J. MORGAN REES emphasised the inconvenience caused by nursing infectious cases at home. Dr. JOHN HUTSON advocated the *notification* of *suspected* cases, as distinct from developed cases.

Poliomyelitis.

Dr. G. MURRAY LEVICK read a paper on the Organisation of Treatment for Infantile Paralysis. He said that unfortunately the acute attack was *often undiagnosed, the signs of paralysis following* a supposed attack of influenza. Prompt treatment depended on the alertness and coöperation of general practitioners and was very important, since it affected the ultimate issue. An important diagnostic point was muscular tenderness in acute pyrexia without obvious cause. The new anterior poliomyelitis antitoxin should be administered in the first few hours, partly intrathecally and partly intravenously, but was worth giving at any time during the fever. It was of the utmost importance to posture the parts correctly at the very outset, without pressure from bandages. When the antitoxin was given, cerebro-spinal fluid could be withdrawn, if desired, to relieve pressure. Measures must be taken to preserve the contractility of all affected muscles for at least a year before hope was abandoned, and the patient must be in the hands of specially qualified people. A common mistake in electrical treatment was excessive faradic stimulation; faradic current should never be given in the early stages and deep effleurage might do great harm. The acute attack was a great shock to the nervous system, and general rest and heliotherapy should be given for months or years. The best lamp was the carbon filament, with a mercury-vapour tube for ultraviolet rays. The paretic muscles should be irradiated with intense red light. Postural treatment might demand prolonged recumbency to prevent spinal and costal deformities. Such cases should be nursed in the open air all the year round. Organised institutional treatment alone could meet economically the many needs of these patients over long periods. There was a serious lack of organised treatment for paying patients of moderate means. These children needed a different environment and different education from those catered for by the public schemes that were now spreading throughout Great Britain. Dr. Levick showed slides illustrating the work at Chailey. Affected limbs should be slung from an overhead bar and not laid flat on splints. Slinging was a most important factor in re-education and recovery of tone. It allowed free movement within the child's limits without permitting stretching of the paretic muscles. It was no more unreasonable to demand daily treatment for years for these children than to demand daily education for healthy children.

Dr. HARRIES raised the problem of whether schools should be broken up on the appearance of a case of poliomyelitis, and commented on the remarkable benefits of modern treatment.

In reply to questions, Dr. LEVICK emphasised the importance of keeping paretic limbs warm and the advantage of a light windproof material over a single layer of wool for outdoor nursing in winter.

REVIEWS AND NOTICES OF BOOKS

Recent Advances in Medicine.

Sixth edition. By G. E. BEAUMONT, M.D., and E. C DODDS, M.D. London: J. and A. Churchill. Pp. 442. 12*s.* 6*d.*

THE success of this volume has been so great that new editions have been called for almost yearly since it was first published in 1924. The present edition differs very little from its predecessors, and its scope remains unchanged. Room has been found for some account of the Aschheim-Zondek test for the detection of pregnancy in the early stages, and a few pages are given to the discussion of uræmia. The account of treatment of pernicious anæmia by stomach extracts is also new, and a few minor additions and alterations have been made in other parts of the book.

On the whole the authors have well maintained their practical attitude to the subjects discussed, and their selection of material has been wisely made. Any temptation to include much recent work which is still only of theoretical interest or has not been fully confirmed has been resisted, and apparent omissions may indicate only that certain "advances" do not yet fulfil the rigid conditions which the authors have laid down for themselves. The recent use of the higher carbohydrate diets in diabetes is not mentioned in the chapter on this disease, where the indication is that the "veg. A," or 5 per cent. carbohydrate group, must be accurately weighed out to the exact ounce. The reputed value of salyrgan in cardiac as distinct from renal œdema is also ignored. The instructions given are so clear that the laboratory methods described can be easily carried out without expert assistance. Those who wish to keep up to date in medicine, as well as students for the higher examinations, will find here a most excellent review of modern additions to medical technique.

Medical Administration of Teaching Hospitals.

By EMMET B. BAY, M.D. Chicago: University of Chicago Press. 1931. Pp. 136. 9*s.*

THE investigation reported in this volume is one of a group of studies which Dr. Michael Davis has been enabled to subsidise through a grant generously made by the Rockefeller Foundation. Dr. Bay has selected 19 hospitals and clinics, nearly all of which are associated with medical schools in the United States. The aim of the investigation is not to propose a universally acceptable plan of organisation, but to present a comparison of many organisations, in order that those interested in the problems may draw some useful conclusions for themselves.

The fundamental differences between the hospital systems of the United States and of England make actual comparison between the problems of the two countries rather difficult. In regard to teaching, for example, Dr. Bay says that in the United States "in hospitals connected with medical schools most of the patients used by the staff for teaching purposes are those who occupy free beds. Pay-patients, whether in wards or private rooms, are used only occasionally. For this reason the number of free beds in any teaching hospital is always important." In England, where practically all the beds in the teaching hospitals are at least nominally free, this problem of pay versus free beds does not arise. Again, there seems to be in the United States a conflict of policy between the lay admission office and the teaching staff, similar to that which may occur between the advertising side and the editorial side of a newspaper. The admission office is primarily interested in what the patient can pay; the professional staff are interested in the medical needs of the patients and their value for teaching purposes. In England the admission of patients is almost without exception determined by the medical staff, and the office has only to register the admission. Financial considerations do not arise, though the hospital almoner is becoming more and more active in ascertaining how much of his maintenance expenses the patient can fairly be asked to pay, and in persuading him to contribute according to his means.

Other problems investigated by Dr. Bay, such as the Open or the Closed Staff, Tenure of Appointments, Governing Bodies, the Executive Committee of the Medical Staff, Hospital Superintendents, the Functions of the Dean, and many others, give ample material for consideration by the hospital administrator in England, and the information afforded and the conclusions drawn from this information by Dr. Bay are of interest.

The general conclusion reached by most of his readers will be that in a teaching hospital all administration should be determined by two main principles: (1) the business organisation of the institution should be in the hands of the lay governors, and (2) the admission of patients, the nominations for appointments on the hospital and school staff, and the general professional conduct of the work should be in the hands of those best qualified to undertake it—viz., the teachers themselves.

Dr. Bay has written a closely analytical study, which is fresh and stimulating, and should be read by all who are interested in the complex association and interrelation of the lay governing body and of the professional staff of a teaching hospital.

Crippled Children:

Their Treatment and Orthopedic Nursing. By EARL D. MCBRIDE, B.S., M.D., F.A.C.S., Instructor in Orthopedic Surgery, University of Oklahoma School of Medicine. London: Henry Kimpton. 1931. Pp. 280. 15*s.*

THE intention of the author is to supply information which will be of interest to those who have the care of crippled children, assisting them in the recognition and treatment of the more common orthopædic conditions, particularly in the early stages when so much can be accomplished. Chapters on the technique of orthopædic nursing and post-operative duties are followed by others giving a brief, but comprehensive, description of the various forms of paralysis improvable by orthopædic measures, of spinal and joint tuberculosis, of rickety and postural deformities, and of congenital abnormalities. Each section contains a clear statement of the nurse's duties, and the volume closes with a useful glossary of orthopædic terms. Illustrated by 150 photographs and diagrams, lucidly written and well printed, this book presents in simple terms that which every nurse and social worker who is brought into contact with the cripple should know.

Allen's Commercial Organic Analysis.

Fifth edition. Vol. VIII. By Eight Contributors, under the Editorship of C. A. MITCHELL, M.A., D.Sc., F.I.C. London: J. and A. Churchill. Pp. x.+761. 30s.

WITH each succeeding edition of this well-known treatise the original title still used becomes less completely descriptive of the subject matter, for not only are the industrial applications of organic analysis provided, but the sources, isolation, properties, reactions, and methods of estimation of many substances, familiar in scientific circles but not yet employed commercially, are included. The present volume contains contributions by four British and four American authors, and deals with glucosides, the bitter principles of plants, enzymes, putrefaction bases, animal bases and acids, cyanogen compounds, and the proteins and their digestion products. The subject matter includes much material of interest to the physician, pharmacist, and biochemist, notably the sections on digitalis, jalap, aloes, and other drugs; the enzymes from both animal and vegetable sources; the examination of urine and the estimation of its numerous normal and pathological constituents; urinary and biliary calculi; and the digestion products of the proteins. Nothing, perhaps, illustrates the rapid progress of science more than a comparison of such a work with the corresponding sections in the previous edition of 15 years ago, an interval during which much progress has been made both in the investigation and analysis of new and little known substances. Thus whilst numerous obsolete methods have been omitted newer, more rapid, and, in many cases, more accurate methods have replaced them, and the present volume contains some 50 pages more than its predecessor. The compilation of such a mass of information is a task of no mean magnitude, even for the combined efforts of eight authors, and the high degree of accuracy shown renders the volume one of outstanding merit. Frequent references throughout the chapters and a concise bibliography at the end of each enable the reader to trace original sources and to supplement, where necessary, the information given.

The subject matter of this volume does not lend itself to much diagrammatic or pictorial representation; the few illustrations consist chiefly of enlarged drawings or photomicrographs of crystalline organic compounds. There is a good index and the book will prove of value to a large group of workers, especially when faced with a problem off the beaten track.

Les diagnostics anatomo-cliniques de Paul Lecène.

Recueillis par ses élèves. I. *Généralités.* By P. PAVIE. *Lésions du sein.* By P. MOULONGUET, Professeur agrégé à la Faculté de Médecine de Paris, Chirurgien des Hôpitaux. Paris: Masson et Cie. Pp. 192. Fr.45.

THIS volume is the first of a series of similar manuals projected by the late Paul Lecène, who only lived to write the general preface. The books themselves have been undertaken by his pupils, who, with exemplary piety, reproduce the whole of the original manuscript of the preface at the beginning of each volume. The present contribution consists of 52 pages of a general account by Dr. Pavie, of the value of pathological investigations in surgery, and 140 pages by Dr. Moulonguet, describing the diseases of the breast from a clinical and pathological standpoint. The work makes no great claim to originality, but describes briefly the ordinary lesions of the breast, with their pathological interpretations along the generally accepted lines. The book is thus designed rather for the student than the specialist, and is made especially valuable to him by the large number of excellent illustrations, for the most part from photographs. The only illustrations in colour, two in number, have been lavished upon the rare condition of "fat-necrosis" of the breast. In the interest of the reproductions the whole book has been printed upon thickly coated paper, making it disproportionately bulky and heavy.

Recollections of an Old and Observant Practitioner.

By JOSEPH DANIEL MCFEELY, F.R.C.S.I. London: Edward O. Beck and Co. 1931. Pp. 246.

IN this little book Dr. J. D. McFeely, who has retired from practice after long services as general practitioner, hospital surgeon, and sanitarian in Dublin and Liverpool, sets out his experiences. The author has a low opinion of most of the modern developments of professional life, pours contempt upon the panel system, and regrets the old days of apprenticeship. He mixes sound therapeutical notes with political diatribes and Irish stories insufficiently new; and he writes with a sense of grievance. But the impression is made upon the reader of great sincerity.

British Journal of Children's Diseases.

To the July-September number of this journal (vol. xxviii.) Dr. I. M. Allen contributes a paper on Neurosis in Childhood, based on 160 cases personally investigated in the out-patient department of the National Hospital, Queen-square. He divides the factors which give rise to a neurosis into two groups—viz., those which make the child less able to face his environment and difficulties, and those which appear to excite the symptoms of a neurosis in the child at various stages of development. The former include physical and mental disabilities, biochemical disturbances, a special physical habitus, the position of the child in the family, father deprivation, lack of parental training, and maternal inexperience in association with a strong sense of responsibility. The exciting causes include the birth of the next child, illness of the patient or an older member of the family, rearrangement of family relationships, failure of social adaptation, school discipline, surgical operations, accidents, puberty, and economic maladaptation. Twenty-two illustrative cases are described, and the diagnosis and treatment of neurosis in childhood is discussed.—Dr. Francis Bach contributes a paper on the Incidence of Rheumatic Fever, based on observations in Great Britain, North America, Holland, Germany, and Scandinavia. He comes to the conclusion that the disease is widespread, its incidence being related to certain sociological and geographical factors. It is common in those parts of the world where the resistance of the individual is lowered by overcrowding, poverty, and inadequate diet and where the *Streptococcus hæmolyticus* is a not uncommon inhabitant of the human nasopharynx, while it is rare in those countries where poverty and overcrowding are absent and the *S. hæmolyticus* is not an inhabitant of the human nasopharynx.—Dr. J. B. Ellison describes two cases of thrombophlebitis complicating scarlet fever in boys aged 6 and 10½ years respectively. They presented the characteristic features of the condition described by Moorhead and Abrahamson under the title of phlebitis migrans—viz., dissemination of lesions in time and space, phlebitis of the lungs and abdominal viscera, and a favourable prognosis.—The abstracts from current literature are devoted to nervous and mental diseases.

of obscure origin. Aluminium has been found in certain plants—e.g., *Orites excelsa*, an Australian tree, and in various kinds of *Symplocus*, which as long ago as 1690 were called by Rumphius *arbor aluminosus*; but whilst Zbinden and Dutoit found it in human blood, and Wiechowski[1] estimated the quantity as over 0·004 per cent., Fox and Ramage failed to detect it there. Its presence in the feathers of birds, notably the jay, is to be regarded with some suspicion as feathers are apt mechanically to retain fine dusts, such as dried clay, which contain alumina. A considerable amount of work has been done on the effect of feeding various kinds of animals with food containing aluminium; in some cases the doses given were grotesquely large if the object of the experiment was to elucidate the question of the effect of aluminium cooking vessels and food containers on those consuming the food so prepared.

In a recent annotation[2] reference was made to controlled work at the Rowett Institute on the addition of aluminium to the diet of freshly weaned pigs. Since then the subject has been dealt with in another paper by this author. K. Mackenzie has reported[3] further work done there on young rats, and D. Tourtellotte and O. S. Rask similar work[4] in America. Mackenzie introduced the aluminium in the form of a baking powder containing acid calcium phosphate and sodium aluminium sulphate, whilst Rask and his colleague used aluminium chloride, the percentages of the metal in the foods, which were alike in other respects, being respectively 0·1 and 0·06. The controls used by Mackenzie received similar rations but containing only about 0·0001 per cent. of aluminium naturally present. He found that both groups throve well, the weights increasing from about 40 to 200 grammes in the course of 12 to 16 weeks. Analyses of the food, urine, and fæces were made for periods of 7 to 12 days. In the rats receiving only the aluminium naturally present in the diet the urine contained from 1 to 2 per cent. of the total input, in those receiving added aluminium only about 0·01 per cent. of the input was found in the urine, demonstrating that either the metal reached the circulation in mere traces, or was held up in the tissues. The large proportion—from 84 to 95 per cent.—recovered in the fæces showed that absorption was at any rate small. The difficulty of collecting the excreta completely may well account for the remainder, since analyses of liver, lungs, heart, stomach, and small intestine in groups of 8 to 10 rats showed aluminium contents of the same order in both those receiving this element and the controls. Tourtellotte and Rask's previous work led them to conclude that aluminium compounds are not toxic or detrimental to any biological function when present in diets in concentrations up to 600 parts per million (of the same order as they and Mackenzie had given to rats), that they were not appreciably absorbed out of the intestinal tract, and that animal tissues contained less than 2·0 parts per million of aluminium. Their conclusions having been challenged by other workers these authors have confirmed their work by showing that in some cases the challenge was based on erroneous interpretation of spectrograms. In the experiment referred to, which was directed solely to investigating directly the absorption of aluminium, the combined liver, spleen, kidneys, and testes or ovaries of individual rats, and the combined thyroids of six rats showed only 1 part or less per million of aluminium, amounts similar to those previously found by them and others in animals fed on aluminium-free diets. The rats appeared to be healthy and normally fertile.

In face of these facts and of a statement by the German Board of Health that no injury to health or indication of absorption could be found in dogs fed with aluminium hydroxide for over 12 months, it is difficult to attribute groups of symptoms, such as are described by Dr. LeHunte Cooper in a recent pamphlet,[5] to the use of aluminium cooking vessels, especially as the authors whose feeding experiments are quoted in support of his deductions from clinical observations are those whose work Tourtellotte and Rask have shown to be in error.

LATENT JUVENILE TUBERCLE.

Clinicians have often contrasted the relatively acute forms of pulmonary tuberculosis met with in adolescents and young adults with the chronic fibroid phthisis of middle life. Such a rough classification may serve a useful purpose if it emphasises the fact that the young are specially susceptible to the acuter manifestations and the more rapidly progressive forms of the disease. In these cases the patient's life may depend upon early diagnosis and immediate treatment. The adolescent suffering from early infiltration limited to a few lobules of one lung, and whose admission to sanatorium is delayed for a few weeks, will probably spend the waiting period wandering about the streets in a pathetic attempt to obtain the advantages of "fresh air," and may arrive at the institution with both lungs severely affected; but the life of a middle-aged working man whose lungs have been the seat of a smouldering infection for years will not be endangered on account of the length of a waiting list. It would, however, be a mistake to imagine that there are any age limits to the various types of pulmonary tuberculosis, for even among the young latent and sluggish forms of the disease are common. A girl in adolescence may acquire chronic fibroid phthisis of a type so indolent that no inkling of the true cause of a chronic malaise may arise until some increase in a cough, previously slight and intermittent, draws the practitioner's attention to the chest, a few sticky adventitious sounds or some slight irregularity in the breath sounds rouse his suspicions, and a skiagram shows extensive fibrosis of the lungs.

In the latent or sluggish type of tuberculosis in young people the problems of diagnosis, prognosis, and treatment are not easy to solve. Three French observers have discussed these problems anew.[1] Symptoms may be so slight that even the patient's mother may overlook them, there may be no loss in weight at a time when the disease is already firmly established in both lungs; even a progressive gain in weight is not unknown. The cough which is so marked a feature of the common forms of phthisis may be entirely absent for prolonged periods. A little "phlegm from the throat" in the morning does not suggest that anything is wrong with the chest. Should persistent lassitude drive the patient to her doctor's surgery a careful examination may reveal no physical signs of disease. The temperature is found to be normal, and a morning and evening record kept for a period of a week or more by the district nurse shows no evidence of fever. Finally, a sample of sputum, obtained with difficulty, is sent to the public health laboratory, and, to use the patient's formula, "no trace whatever of the disease is found." Yet if a skiagram is obtainable at this stage it may show unequivocal evidence of pulmonary fibrosis, calcifications, and even fibrous-walled cavities in one or both lungs. The difficulties of prognosis may be almost as great as those of diagnosis, for neither symptoms nor physical signs, nor even a single radiogram, may supply definite evidence whether the disease is still active and progressive. X ray examination may prove that calcification or dense fibrosis has taken the place of caseous matter in many areas, but as a rule shadows less intense than those cast by the above will leave interpretation in doubt. Obviously, if the disease has already been soundly healed by natural processes no treatment beyond the observation of the rules of hygiene is indicated, but if there is any evidence that complete arrest has not been secured the question of sanatorium treatment will call for consideration, and it may not be easy to decide if this should be recommended.

[5] The Danger of Food Contamination by Aluminium. London: John Bale, Sons and Danielsson.

The Insurance Act provided for the sanatorium treatment of industrial workers. We have thus been able to observe the results of treating chronic fibroid phthisis in the form of the disease typically seen in middle-aged working men on a large scale. The results have been profoundly disappointing, though the sanatorium-colony where the patient is able to undertake carefully selected work despite his disease has met with a measure of success. Ordinary sanatorium treatment may cause temporary amelioration of symptoms in patients of this type, but it does not restore damaged lungs or working capacity. The young patient suffering from the form of disease we are considering resembles the middle-aged patient. The disease is not amenable to collapse therapy, the only form of active treatment which can be described as curative, and prolonged periods of sanatorium treatment are costly to the community and wearisome to the patient. A disease which has persisted for months or years, which has already resulted in permanent damage to the lungs, is unlikely to yield to a simple change in the manner of life of its victim. If, however, the opposing forces of the patient's resistance and the disease are almost balanced, a period in a sanatorium may suffice just to tip the scale and check the further spread of disease. Further, an appreciation of the true position can best be obtained by a period of observation in a sanatorium. During this period an investigation can be made which will include a search for constitutional evidence of active disease, particularly with regard to the patient's temperature at rest and after activity; serial skiagrams, to determine whether there is any change in the character and extent of the shadows; and a more complete search for tubercle bacilli in sputum and fæces. Microscopical examination of the sputum may not be sufficient to determine if tubercle bacilli are still at work. In the more active forms of tuberculosis the bacilli swarm in the diseased areas, and can be found in almost every sample of sputum examined. In the latent and sluggish forms the bacilli are often absent or difficult to find. Inoculation experiments with guinea-pigs may be necessary to determine their presence. If at the conclusion of these investigations no evidence of active disease is found, the patient may be discharged with the assurance that a normal if sheltered life may be resumed. If any evidence of active disease is forthcoming residence in the sanatorium may be prolonged for a further period, or the patient may be discharged to continue treatment on sanatorium lines under the care of her own practitioner at home.

READING IN HOSPITALS.

THE Dean of St. Paul's gave fresh impetus to the movement for hospital libraries in a whimsical address at the annual conference of the Library Association held at Cheltenham last week. He assessed the reading public at some 17,000,000 persons, each of whom on an average devoured 12 novels a year and would appreciate a supply of books when invalided. Lieut.-Colonel J. M. Mitchell, secretary of the Carnegie United Kingdom Trust, who occupied the chair, expressed a doubt whether public libraries as a whole had taken the part they might in providing books for patients in hospitals. There was no reason, he said, why men and women who were confined to hospitals should be deprived privileges which sick persons were granted in their own homes, and he promised the support of the Library Association in helping hospital authorities to develop an experimental service of books. Sir Bruce Bruce-Porter, who followed Dean Inge, remarked how vital to the sick is the companionship of books. There was, he thought, urgent need for recasting the side of hospital life dealing with the mental life of its inmates. He would set aside in each hospital a large room for a library which could also be used as a dining and reading room. The supply of books must, he thought, be organised on a national plan. Voluntary effort was good, but the post of librarian in a big hospital was onerous enough for a whole-time job. The helpers must be able to sense the type of book which would interest their patients and the librarian must have knowledge of the books he recommends in the same way as the physician should be fully acquainted with the composition of a medicine he prescribes. For a tuberculous patient, for instance, a book on the Brontë family, in which six children are portrayed as dying of consumption, would not be as suitable as the lives of Voltaire, Emerson, and Ruskin, who all lived to advanced age in spite of this disease. Later, at the summer school of librarianship in Birmingham, Colonel Mitchell expressed his pleasure that the hospital library problem was being taken up seriously by the Library Association, for he believed that quiet leisurely reading was among the most important of therapeutic agencies. Mr. C. E. A. Bedwell, house governor of King's College Hospital, frankly stated the conflict between the aims and ideals of hospital and library, but did not despair of its solution. It seems that some 2000 hospitals and institutions are already provided with books through the hospital library organised by the British Red Cross Society and Order of St. John, and Sir Arthur Stanley is now asking hospitals with 100 beds (or fewer) to contribute on the basis of a guinea a year for the use of the library, and larger hospitals to contribute two guineas. Many voluntary hospitals have agreed to subscribe on this basis, and appropriate grants have been voted by committees of the London County Council. So far, the whole of the hospital work has been done by voluntary librarians, but whether this will continue to be possible is doubtful.

ANNOTATIONS

INCIDENCE OF DISEASE AMONG DAIRY COWS.

It has been realised for some time that the average milking life of a dairy cow is short, and estimates varying between 2 and 5 years have been given. In view of the fact that a cow does not attain her greatest productivity until about five years after her first calving (and subsequently only declines slowly for several years) it is clear that milk carries a heavy economic burden in the wastage occurring among the cows which produce it. During the last few years attention has been directed to the seriousness of this problem of cow wastage and, as a first step in its attack, several schemes have been started which aim to measure, and to determine the relative importance of the factors responsible for, the losses from our dairy herds. In Scotland a committee was appointed to collect data, and they commenced operations in January, 1930; their scheme covered 490 milk-recorded herds, and an interim report issued by the Hannah Dairy Research Institute, Ayrshire, briefly summarises the causes of the disposal or death of some 3600 cows. In England wide inquiries have been undertaken at Cambridge and Reading, the former starting in October, 1928, and the latter in October, 1929; these two centres have been working in close touch and on identical lines. Others have also collected data on the question—notably Mr. W. Lawson in East Sussex and Mr. G. H. Garrad in Kent—and the results so far obtained by all English workers have been very consistent. In the following paragraphs the Scottish and the Cambridge (as typical of the English) figures are discussed; the methods of classification in these two cases have differed somewhat, but with a few minor adjustments the results can be presented in comparable form. The percentages of the total disposals accounted for by the various causes were as follows:—

—	Scotland.	Cambridge.	
		1928–29.	1929–30.
Normal causes—			
Sold as surplus stock ..	19·4	17·4	20·9
Poor milk yield	16·6	19·6	19·2
Accident	1·5	1·2	1·4
Old age	4·9—42·4	5·3—43·5	4·0—45·5
Disease—			
Failure to breed	17·2	23·7	26·8
Abortion	2·1	3·6	3·8
Udder diseases	15·0	7·0	4·7
Advanced tuberculosis and Johne's disease ..	5·4	10·4	9·6
Failure in tuberculin test	2·8	2·4	1·8
Miscellaneous	15·1—57·6	9·4—56·5	7·8—54·5
	100·0	100·0	100·0

The first four causes have been grouped together as above in the Scottish report, the idea being to separate them off from the definite wastage due to disease; in passing it is of interest to note the very small proportion of cows that live long enough to enter the "old age" group at their disposal. Under the next heading it is seen that sterility is easily the largest single factor causing wastage. Abortion appears relatively unimportant, but it must be remembered that some cows returned as sterile may really have aborted in very early pregnancy, or be suffering from the after-effects of abortion. These reproductive diseases together account for roughly 20 per cent. of the total disposals in Scotland, and as much as 30 per cent. in England. Udder diseases, on the other hand, are more common in Scotland than in England. Tuberculosis and Johne's disease have been put together in the table because it is probable that the two are often confused; this group is responsible for 10 per cent. of the total disposals in England, but only 5 per cent. in Scotland. Failure to pass the tuberculin test appears as a low cause of wastage, but it must be remembered that only about 15 per cent. of the cows are exposed to this risk—i.e., belong to tested herds. In the Cambridge data it was found that approximately 3 per cent. of the cows actually tested failed during the year—i.e., 1·5 per cent. at each of the six-monthly tests. From the statistical point of view, "miscellaneous" is an unsatisfactory grouping: it comprises, chiefly, cows that die at or just after calving, cows that die from unknown causes, and cows returned as suffering from "bad feet."

The Cambridge data cover approximately 13,500 cows belonging to 540 herds situated in the counties of Bedford, Cambridge, Hertford, Lincoln, and Norfolk. In the two years the total number of disposals was 2849 and 3165 respectively; these give an average disposal of 22·30 per cent. of the cows in the herds per year, from which it can readily be calculated that the average length of life, in one herd, of a dairy cow is very close to four and a half years. The average total milking life must be rather longer, as a proportion are sold in milk or in calf, and so presumably survive for some time in other herds. As near as it is possible to estimate, it seems that the average total milking life lies somewhere between six and seven years. Though the data discussed above have all been derived from milk-recorded herds, other information that is available indicates that the non-recorded herds would yield very similar results, were it possible to obtain data from them.

One point arises from the table on which it may be well to insist—namely, that from the farmer's point of view tuberculosis is relatively unimportant as a cause of wastage. This makes his strenuous and expensive efforts at its eradication the more praiseworthy, and shows that he realises the necessity of making his milk safe for human beings. It will probably be agreed that he should be given sympathetic help in order that the progress of recent years may be maintained.

THE PATHOLOGY OF MEASLES ENCEPHALITIS.

CONTROVERSY still centres on the nature of the encephalomyelitis which occasionally follows measles, and two recent papers throw some fresh light on it. F. Wohlwill in 1928 gave a clear description of the pathology in two cases in which he found as the chief lesion perivascular zones of demyelination in the brain and spinal cord. This description was soon after confirmed by investigations on the Continent and in America, as well as in this country. At present there is little question that the lesion is histologically very similar to that of post-vaccinal encephalomyelitis, and is not, at least in the great majority of cases, a hæmorrhagic encephalitis, as was at one time supposed. Undoubtedly the latter condition may also occur after measles, but since the characteristic perivascular demyelination of this form of encephalitis has been recognised the hæmorrhagic nature of the condition has fallen somewhat into the background. The report of a case from Paris by P. Lechelle, I. Bertrand, and E. Fauvert[1] reopens this question. Their case was complicated by thrombosis of the superior longitudinal sinus, and though they found the perivascular zones of demyelination described by other authors, these contained so much effused blood that they were inclined to attribute the destruction of the nervous tissues to hæmorrhage rather than to a neurolytic process. They did not think, however, that the hæmorrhage resulted directly from the sinus thrombosis, but rather that both were due to an encephalitic process. On the other hand, A. Ferraro and I. H. Scheffer[2] have lately published reports of the pathological examination of six cases of measles encephalitis in New York, two of which occurred in May and June, 1928, and four in March, April, and May, 1930. The lesions were almost the same in all, and consisted mainly of a perivascular demyelination with some destruction of axis-cylinders and proliferation of microglia. They consider that the lesion which they observed is "comparable to and even identical with" those which have been described in post-vaccinal encephalitis, and in the "paralytic accidents" of rabies vaccination. Whether it is a true inflammatory process or a special form of encephalopathy they leave an open question, since inflammatory cells are scanty in or even absent from the lesions. They incline to the view that this form of acute disseminated encephalomyelitis is a toxic reaction of the central nervous system developing in a number of different virus infections, but they make no attempt to explain the undoubted fact that this form of encephalomyelitis has become much more common of recent years.

BIOLOGICAL DATA.

WITH the completion of the six volumes of Tabulæ Biologicæ in 1930, the original purpose of this work was accomplished, but in order to keep such a comprehensive reference book up to date, it has been found necessary to issue supplementary volumes in the form of a quarterly journal, under the title of Tabulæ Biologicæ Periodicæ. We have before us[3] three of the four parts which go to produce the first volume of the supplement which is to form volume 7 of the original publication; it is to contain approximately 420 pages when complete. Subscribers to the original work are to receive the present volume at the reduced sum of R.M. 48. and to them the acquisition of this volume will be essential, while the possession of the earlier volumes will be indispensable to those who think of purchasing this volume. Many of the subjects comprised in this supplement are of the nature of additions to or amplifications of data contained in the original work, but, with the rapidly extending knowledge of the subject of biology, new sections have been added. To attempt to give a summary of the contents would be like describing the subject matter of a dictionary; suffice it to say that the needs of every branch of biology are well provided for. Thus while medical readers will find ample data on the vitamin, iodine, or mercury content of food materials, on experimental phonetics, or on the physiological effects of work or athletics, the pure physiologist will value the tables of physico-chemical constants of blood and tissue fluids, or the alcohol content of various organs of fowls exposed to an atmosphere saturated with alcohol—to take a few examples at random. For the plant cytologist there is an exhaustive list of chromosome numbers extending over 35 pages. References to the original sources of the data supplied are given throughout, and the work will be invaluable as a means of tracing those pertaining to every branch of biological science.

THE TIME OF CONCEPTION.

CONCEPTION is usually reckoned to take place on the actual day of cohabitation. There are, however, several factors which may cause appreciable delay between coitus and impregnation. Prof. R. Kräuter[1] points out that in order to give satisfactory answers to the questions, often put, of whether impregnation can occur at any time, whether there is a sterile period and whether there is an optimum period, it is necessary to know certain factors. These are the time taken for the spermatozoon to enter the cervix and find the ovum; the viability of sperm; the time of ovulation and the viability of the ovum. According to most authorities, the semen usually enters the cervix at or shortly after ejaculation and is distributed by the rhythmical contractions of the uterus, but delay may be caused if it is voided into the anterior vault or near the orifice of the vagina. The time the spermatozoa take to reach the ovum in the ampulla is not definitely established, but Lott calculated from their rate of chemiotactic movement—about 3·6 mm. per minute—that it would be between three-quarters of an hour and an hour. This may be extended by any cause of obstruction, but Birch and Hirschfeld have, according to Prof. Kräuter, demonstrated seed in the tubes 14 to 16 hours after coitus. Views on the viability of semen in the female genitalia are very varied, some authors holding that it lives only for two days, and one—Nürnberger—that it keeps its motility for a fortnight. It is, however, doubtful, as Prof Kräuter points out, whether a motile seed is necessarily still fertile. The time at which ovulation takes place is equally dubious, but from a symposium of observations Prof. Kräuter deduces that in a normal cycle of 28 days it may occur at any time between the seventh and the nineteenth days from the beginning of the menstrual period—most probably between the fourteenth and sixteenth days. He could find no record of ovulation in the last four days before a period. In qualification of these data, he reminds readers that ovulation may be much modified by various stimuli, such as disorders of menstruation, drugs, operations, and even possibly by coitus. It is, he says, agreed that the ovum enters the tube immediately, but its viability is a matter of speculation and is given by some writers as a few hours and by some as several days. Döderlein thinks it remains fertile for fourteen days.

[1] Zeits. f. Arztl. Fortbildung, May 1st, p. 276.

So far as these observations go, it appears that coitus at any time between two periods may lead to conception. If it takes place immediately after menstruation, an early ovum may be fertilised or the seed may remain active until ovulation. If it occurs shortly before menstruation, however, it is not likely to lead to pregnancy, unless the ovum remains fertile for longer than is generally believed. Statistics quoted by Prof. Kräuter show that almost 50 per cent. of the conceptions in the group studied occurred in the interval, 41 per cent. in the postmenstruum, and 9 per cent in the premenstruum. But he does not define these terms exactly. Accurate figures are not easily obtained, and it may be noted that Knaus [2] insists that in the ordinary 26–30 day cycle conception is only possible between the eleventh and seventeenth days.

THE TREATMENT OF HÆMORRHAGE FOLLOWING PROSTATECTOMY.

THE respective merits of various methods of stopping hæmorrhage during and following operations for removal of the prostate were discussed last year at a meeting of the Section of Urology of the Royal Society of Medicine.[3] Mr. Kenneth Walker, who opened the discussion, had tried packing to stop oozing after the Freyer operation in earlier days but found it unsatisfactory owing to necrosis and the unpleasant state of the bladder when the packing was removed. Then he had tried hæmostatic bags, but these did not always control the hæmorrhage and often did not exert uniform pressure on the prostatic cavity. Mr. Walker said that he now preferred the open operation where possible, and did not spend long in trying to secure bleeding points deep in the prostatic cavity. If bleeding did not cease after placing the suture, he used light packing. In cases not suited for the open operation he used packing, leaving the pack in situ for six or seven days, and trusting to the frequent instillation of mercurochrome after its removal to clear up the sepsis. Mr. Swift Joly also praised the Thomson-Walker open operation, which gave more perfect hæmostasis than the earlier methods. In his experience the flavine pack gave pain and hæmorrhage was apt to follow its removal. Sir John Thomson-Walker explained that he himself did not prolong the operation by seeking bleeding points but packed round a catheter. He removed the packing in 48 hours, but replaced it if bleeding recurred. Mr. G. E. Neligan and Mr. Jocelyn Swan alone advocated the use of a Pilcher's bag to control hæmorrhage. These diverse opinions from British genito-urinary surgeons are of interest in view of a discussion held at the New York Academy of Medicine on post-operative treatment of urological cases, more especially cases of prostatectomy.

The opening paper of this discussion by Dr. H. G. Bugbee of New York is printed in the July number of the *American Journal of Surgery*. American specialists are apparently almost unanimous in their approval of hæmostatic bags. A few of those who took part in the discussion at the New York Academy of Medicine appeared to prefer the use of gauze packing but all agreed that the best method of dealing with oozing from the prostatic bed was by means of pressure rather than by an open operation that aimed at ligature of bleeding points. It must be borne in mind that the majority of those who took part in the American discussion were advocates of the two-stage operation in which a free exposure of the prostatic bed is difficult or impossible. A point on which American and British genito-urinary surgeons agree is the value of blood transfusion in diminishing the danger of post-operative hæmorrhage.

LIVER EXTRACTS FOR PARENTERAL USE.

THE satisfactory treatment of the pernicious anæmia syndrome is dependent upon adequate dosage of liver or its substitutes. In chronic cases Beebe and Lewis [1] have given as much as 3 lb. of liver a day and in certain instances even such large doses are without effect. There have therefore been repeated attempts to obtain some alternative and more effective method of administering the effective principle. Last year Cohn, McMeekin, and Minot described excellent results following the intravenous use of highly purified extracts, but the technical difficulties of preparation made such extracts impracticable for general use. Gänsslen then reported satisfactory results from treating a case of Addisonian anæmia, that had failed to respond to oral administration, with an intramuscular extract. French observers have also reported [2] a more rapid response to intramuscular injection than to liver by mouth, but unfortunately they gave no details of the method of preparation. In our own columns (1931, i., 857) Castle and Taylor showed that the original G fraction of Cohn, Minot, and their associates, which is the equivalent of certain commercial extracts for oral use, can with suitable care in preparation be satisfactorily administered by intravenous injection. The fraction contained a blood pressure reducing substance, but if given at a rate less than 4 c.cm. a minute, the effects were only slight and transitory. Strauss, Taylor, and Castle [3] have now also found that by a slight modification in preparation of the solution the same G fraction can be used as a basis for an intramuscular extract. The injection of the equivalent of 10 grammes of liver daily of such an extract gave a maximum reticulocyte response in typical cases of pernicious anæmia within five to seven days. They suggest that the extract necessary for a week's treatment when given by mouth may, if given by daily intramuscular injection, suffice for five to six months. Extracts for intravenous use were found to be 15 to 30 times as potent as the equivalent amount given by mouth. Further, certain patients responded to intravenous treatment after oral administration had failed. It is clear therefore that the active principle is more effective when given by parenteral injection than when given by mouth. The discrepancy adds support to Castle's original suggestion that failure of absorption of hæmatopoietic factors contained in the food or elaborated in the stomach is an important factor in the ætiology of the pernicious anæmia syndrome, especially those cases associated with chronic disturbances of the lower intestines and an apparently normal gastric function.

CONGENITAL PYLORIC STENOSIS.

THE treatment of this condition in this country is now predominantly surgical. In his analysis last week (p. 526) of 18 cases at the Middlesex Hospital from 1919–30 Mr. C. MacLeod stated that only the first five were treated medically, the remaining 13 (all the cases since 1924) by Rammstedt's operation. And in introducing the discussion at the Eastbourne meeting of the British Medical Association, Mr. Max Page pointed out (p. 533) that this operation was accepted in this country as the treatment giving the best results. Other views were laid before the section on diseases of children at the recent annual gathering of the American Medical Association at Philadelphia.[1] Dr. Orville Barbour, who opened the discussion, held that spasm plays a part in almost every case of pyloric stenosis, and that this spasm can be relieved by irradiation. He applies what he calls a roentgenotherapeutic test to any case which does not respond to medical treatment within 48 hours. X rays are applied for three to five minutes to the upper part of the chest, when, if the obstruction at the pylorus is due mainly to spasm, the symptoms abate within 24 hours. If the obstruction caused by the tumour is extreme, little or no abatement occurs, but the patient is in a better condition to withstand operation than after a prolonged period of expectant treatment. While some other speakers at the American meeting were in favour of the irradiation treatment, which appears to produce its effects by a non-specific protein reaction stimulating the sympathetic nervous system, others supported the view that in all cases of true hypertrophic stenosis a tumour can be felt, and in most of them early operation is advisable. If after several attempts by trained observers a tumour cannot be found when other criteria are present, the case is probably one of pyloric spasm. It was admitted both at Eastbourne and Philadelphia that radiography is disappointing in the help it gives towards diagnosing between spasm and true stenosis. In America it is an axiom, generally attributed to Sauer, that the skill of the physician is the outstanding feature in the prognosis of pyloric stenosis. From what was said at Eastbourne, it would appear that once the diagnosis is made the outstanding feature in the prognosis is rather the skill of the nurse. Dr. Donald Paterson produced striking evidence of the great difference in post-operative mortality between private and hospital cases, due presumably to the fact that in a nursing-home a baby has the individual attention of special nurses day and night. Reviewing the two discussions, it is evident that the old controversy between advocates of medical and of surgical treatment is no longer acute. It is now agreed that when a definite tumour exists operation is advisable, unless the child had already passed the third month before the symptoms became acute. Medical treatment must be in accord with recent biochemical work. As Dr. Noah Morris pointed out at Eastbourne, babies with pyloric stenosis pass easily into a state of alkalosis; washing out the stomach with sodium bicarbonate solution and the administration of citrated milk are therefore unsafe. We hardly know whether irradiation is to be advised when a well-marked pyloric tumour is present, but the delay of 24 hours involved in Barbour's test is not serious, and further investigation might be made along this novel line. Opportunity to do so is likely to arise, as the malady seems to be on the increase in this country.

A NEW DISEASE.

UNDER the name of "Rift Valley fever" Drs. R. Daubney, J. R. Hudson, and P. C. Garnham describe[1] a fresh human disease which they have identified in Kenya. Like many other profitable things which have lately come to the student of infection, this new information arose from the investigation of veterinary subjects when the authors were asked to look into an excessive mortality among new-born lambs. This, they found, was due to some agent which would pass through a fine Chamberland filter. The condition is not contagious and there are fairly good reasons for suspecting a mosquito as the insect vector, though this point is not yet settled. The characteristic lesion of the disease in lambs is a focal necrosis of the liver, not unlike the condition found in yellow fever, with nuclear fragmentation and cytoplasmic "bodies." In adult sheep the disease is much less severe. It causes abortion and a moderate mortality in ewes and much the same in cows; other domestic animals appear to be immune. During the course of the investigation of the sheep, all the four Europeans involved developed a dengue-like fever, with rigors and severe pains about the joints, the whole attack lasting about four days. It was then found that most of the natives who had been in close contact with the original epidemic in the sheep had had similar attacks. Finally, a man was deliberately inoculated with the filtered plasma from an infected lamb which caused typical reactions in two sheep injected at the same time. He took ill in the characteristic way on the third day, and his blood proved infective to sheep for six days after his temperature rose but for no longer. We understand too that several persons have been infected while working at the disease in animals in this country, and there can be little doubt that we have an addition to make to the list of infections to which man is subject. It is perhaps of relatively little practical moment, but trivial diseases of limited geographical distribution such as this which are followed by a substantial resistance would afford excellent material for the investigation of immunological problems in man.

THE BIOLOGICAL METHOD IN PSYCHIATRY.

ALTHOUGH psychological medicine lends itself to philosophic treatment, general biological method is not always adequately used by psychiatrists who, in their zeal for either purely mental or purely physical categories of explanation, slip into a one-sided point of view, which leaves essentials of organic life, philosophically viewed, out of account. As a healthy corrective to this weakness, Prof. W. A. White opens his work on Medical Psychology[2] with a discussion of the meaning of "organism," and approaches this topic from the angle made familiar to us by Prof. Child in his conception of physiological and dynamic gradients. Having established biological premisses for argument, the author illustrates from biology the value of the concepts of Ambivalence and Conflict in all vital phenomena, so that the familiar occurring at a much later date may be attributed to the too early resumption of work after an illness.

PREVENTION OF DISEASE.

Does not the fact that the increase in number of claimants has been mainly in claims of short duration and among younger insured persons, and the fact that the increase has been in the number of claimants per cent. of society members (§ 17 of the memorandum) tend to show that more advantage is now being taken, especially by the younger insured persons, of the facilities provided for them by the Act? They come earlier, more often, and for slighter complaints, thus perhaps preventing more serious illnesses, and incidentally longer claims. Is not the Act in this way fulfilling one of its objects, about which we hear too little—the prevention of disease? The benefits of the treatment of such conditions as septic foci, which may not render an insured person incapable of work, will be apparent in later years.

The tendency of persons incapable of work, who would not have claimed in earlier years, to claim under present conditions is regarded as a large factor in the increase. There is also a tendency on the part of insured persons to make full use of certificates obtained instead of adhering to their previous attitude of indifference to them, which often resulted in certificates being either refused, torn up, or allowed to lie about at home or in the pocket and thus rendered valueless.

RECOMMENDATIONS.

Study of the memorandum finally leads the Paddington section to make the following suggestions:—

1. To recast the actuarial basis and of sickness benefits according to the health categories and statistics of the various classes of insured persons.
2. To instruct the medical student in health insurance practice.
3. To deal with each case on its merits in the spirit of Article 3 of the N.H.I. (Medical Benefit) Amendment Regulations, 1930.
4. To promote a due sense of professional responsibility in certification, among those in whom it is at present lacking, by general discussions (§ 61 of the memorandum) within the profession.
5. To deal with cases involving negligent or false certification, for purposes of administrative inquiry, through the panel committee and the regional medical staff, and, for purposes of disciplinary action or penalty, through the General Medical Council.
6. To submit any document which reflects on the efficiency or good faith of insurance practitioners before issue to the representatives of the profession for their comments.

COST OF MEDICAL SERVICE IN 1930.

The twelfth annual report of the Ministry of Health which has just appeared (Cmd. 3937. 5*s.*) gives the extent and cost of the insurance medical service in 1930. In England 14,700 doctors were in insurance practice. Medicines and appliances were supplied as part of medical benefit at about 9000 chemists' shops. The number of insured persons entitled to medical benefit was nearly 14,500,000. Medical benefit cost over £8,862,000. Of this sum insurance doctors received over £6,447,000 in respect of their duties of attending and treating insured persons; and £1,927,700 of the balance was paid to insurance chemists for the supply of drugs and appliances. The remainder was expended in adjustments of the main finances of medical benefit to various special conditions arising under the Act, or in the circumstances of insurance practice.

About £200,000 was paid to country doctors on account of mileage, the payments being so calculated as to take account both of distances covered and of the difficulties of locomotion in certain areas which would make distances by themselves an inadequate measure of demands upon doctors' time and energy; nearly £10,000 was set aside to enable country doctors to attend courses of post-graduate study, and to provide them with facilities such as maintenance of telephones, motor-cars, and branch surgeries, or reasonable vacations; doctors received about £196,000 for medicines and appliances supplied by them personally, and for medicines dispensed by them in country districts where patients are out of reach of chemists; and, finally, sums of about £74,000 and £7500 were paid on account of the small numbers of insured persons who exercised their option to obtain treatment, including medicines, through approved institutions, or, with the consent of insurance committees, to make their own arrangements for medical treatment.

On April 1st last 926 insurance practitioners were under agreement with Welsh insurance committees. Of these 29, or 3 per cent., were medical women, representing about 20 per cent. of the registered medical women resident in Wales. The medical men participating in insurance practice were about 55 per cent. of the registered medical men in the country. The central practitioners' fund available for remuneration in Wales amounted in 1930 to £399,229, plus £38,300 allocated in respect of mileage, and £590 to meet certain difficulties in providing medical treatment in rural areas. Medical benefit and administrative expenses together amounted during 1930 to £579,924, as compared with £585,031 in 1929.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: O. D. Brownfield to *Egmont*, for R.N. Hospital, Malta; and C. M. R. Thatcher to *Victory*, for Haslar Hospital. Surg. Lt.-Comdr. J. M. Sloane to *Vivid*, for R.N. Hospital, Plymouth, and to *Keppel*. Surg. Lt.-Comdr. (D) E. R. Longhurst to *Maine*. Surg. Lts.: G. Rorison to *Pembroke*, for R.M. Infirmary, Deal; E. W. Graham to *Adamant*; H. G. Wells to *Godetia*; and D. C. Drake to *Enterprise*. Surg. Lts. (D): L. F. Fairey to *Devonshire*; H. V. Pell to *Victory*, for R.N. Barracks, Portsmouth, and to *St. Vincent*; and L. V. Donegan to *Pembroke*, for R.N. Barracks, Chatham.

Surg. Lt. R. W. Mussen to be Surg. Lt.-Comdr.

Surg. Capt. J. McCutcheon placed on Retd. List.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. H. M. Petty, Surg. Lts. A. P. Trimble, D. M. Dean, and Surg. Sub-Lt. R. W. Riddle to *Victory*, for Haslar Hospital. Surg. Lt. (D) R. Symmons to *Vivid*.

ROYAL ARMY MEDICAL CORPS.

Basil Blewitt to be Lt. (on prob.).

MILITIA.

Maj. R. MacKinnon retires on attaining the age limit, and retains the rank of Maj.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. D. C. Graham, from Active List, to be Capt.

INDIAN MEDICAL SERVICE.

The undermentioned officers retire: Col. J. Fuller-Good and Lt.-Col. E. C. Hepper.

Capt. A. S. Arora relinquishes his temp. commn.

ROYAL AIR FORCE.

Group Capt. H. W. Scott to No. 21 Group Headquarters, West Drayton, for duty as Senior Medical Officer.

SPECIAL ARTICLES

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

OPIUM AND ALBUMINURIA.

THE Calcutta School of Tropical Medicine is investigating the effect of opium on albuminuria, having regard to the general impression that patients suffering from kidney disease stand this drug badly. There appears to be no experimental basis for this belief, but it has been argued that the administration of opium or its alkaloids is inadvisable in nephritis, if only because they lessen intestinal movements, apart from any question of direct action on the kidney. Lieut.-Colonel R. N. Chopra, I.M.S., and Dr. J. P. Bose, however, approaching the question with an open mind, did not admit[1] that any adequate reasons were forthcoming for depriving patients suffering from chronic kidney disease of the relief from pain or distressing cough or pain afforded by opium. They proceeded to try the effect of small or medium doses on a series of hospital cases, some suffering from chronic nephritis of the parenchymatous type, some with ascites, and all with albumin in the urine indicative of damage to the kidneys. The patients were put on a diet of known food value, and the amount of fluid was kept as constant as possible. The daily output of urine and albumin was measured and charted. Opium was given in gradually increasing doses in the form of a mixture, the initial dose being gr. 1 daily, gradually increased to 4 or 5, or in some cases to grs. 8 or 9 daily. Contrary to expectation, in almost all cases there was an appreciable increase in the quantity of urine passed, and in none was the daily output diminished below the average normal. This was attributed, not to direct action on the kidney, but to diminished peristalsis increasing absorption from the gut. The quantity of albumin showed a decrease in most cases; in some it disappeared. There was no evidence, either in increase of albumin or casts, of further damage to the kidney. The blood-sugar in most cases remained constant as before. The general condition of most of the patients improved, but in two slight symptoms of uræmia developed. The number of cases dealt with was only 12, and renal function tests were for some reason considered impracticable The further investigations promised will be awaited with interest.

SELF HELP.

In a report issued jointly by the Dufferin Fund, the Victoria Memorial Scholarship Fund, and the Lady Chelmsford All-India League, is an account of the inquiry into maternal and infant mortality now being carried on by Dr. Margaret Balfour and her colleagues in various parts of India. This inquiry is complicated by social and religious customs, and by the geographical distribution of various diseases of pregnancy, such as eclampsia, anæmia, and osteomalacia. Certain broad facts indicate directions in which effort can be profitably put forth. A series of 200 cases of stillbirth and early infantile death have recently been examined in Bombay, Calcutta, and Madras. Of these, the complications of labour comprised the largest single group, accounting for 19·5 per cent. Antepartum hæmorrhage provided 13·5, and the toxæmias of pregnancy 15·5 per cent. Only 10·5 per cent. of the deaths were put down directly to tropical diseases, those figuring chiefly being malaria, anæmia of pregnancy, and dysentery. The incidence of syphilis was 14·5 per cent., or including probable and possible cases 18·5 per cent. It is noted that whereas women of the hospital classes in Glasgow gave 9 to 10 per cent. of positive Wassermann reactions, series of women examined in Bombay, Madras, and Calcutta gave 13·6, 12·5, and 13·4 respectively. Out of a total of 144 placentas examined, no fewer than 57 showed evidence of gross disease or abnormality, and 5·5 per cent. of the deaths were accounted for primarily by diseases of the placenta. Much of the report of the Scholarship Fund is devoted to the question whether or not it is desirable to utilise the services of *dais* (the illiterate midwives of the country) for maternity work. By general agreement these women, in their original state, are dirty and dangerous, and it is difficult to imbue them with even the most elementary ideas of cleanliness and efficiency. In some localities, however, an attempt at training has been made by enthusiastic workers, with a considerable measure of success. The work of educating them may be distasteful and unsatisfactory, but there is no practicable alternative. Properly trained midwives are not likely to be available for many years to come, apart from the difficulty of prevailing on them to reside in isolated situations. The cognate scheme for training schoolteachers to render elementary medical and surgical aid in the villages is advancing rapidly in many districts. It certainly seems wise to avoid utilising the *vaids* and *hakims* for this purpose when literate substitutes are readily obtainable. And it is evidently with reluctance that women doctors have at length decided to endorse comprehensive schemes for the training of indigenous *dais*.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

DIFFERENTIAL FERTILITY.

A STUDY of fertility according to geographic areas in this country has been made for the division of research of the Milbank Memorial Fund, and is published in their latest Quarterly Bulletin. Race, social class, and urbanisation, each known to affect fertility, were held constant for each area. In the East the fertility-rate of women on farms is found to be about 50 per cent. higher than that of women in cities. In the West the farm women are 75 per cent. more fertile. Women of the "white collar" class have a higher fertility in the West (except in California) than in the East. Among women of the labouring class this distinction is not found. In fact, the highest fertility among women of this latter social grouping is found in New Jersey and Pennsylvania. The labouring class is more fertile in all areas than is the "white collar" class. It is suggested that further research be made to determine what are the social factors responsible for the higher fertility in Western areas and for an observed tendency toward stabilisation of fertility in urban areas.

THE BROAD TAPEWORM.

As long ago as 1907 Stiles foretold that infestation with *Diphyllobothrium (Dibothriocephalus) latum* would become endemic in North America, as it already is in Japan and on the coast of the Baltic and the great

---

[1] Ind. Med. Gaz., June, 1931.

African lakes. Infested fish have been found in Northern Minnesota, the Portage Lake region of the State of Michigan, and in the vicinity of Winnipeg. This tapeworm undoubtedly has been introduced by immigrants from Northern Europe. During the last five years Thomas B. Magath and Hiram E. Essex, of the Mayo Foundation, have made a detailed investigation of the waters of Minnesota and the neighbouring territory of Canada, and have tabulated and plotted their findings in a contribution to the *Journal of Preventive Medicine* for July. More significant than their actual discoveries of plerocercoids are the observations they have made upon the life cycle of this helminth under natural conditions. Much emphasis has been laid in the past upon the importance of dogs and certain wild mammals as natural reservoirs of infestation. Magath and Essex give reasons for believing that human sewage is of far greater importance. Of eggs from human sources, 80 per cent. developed active coracidia. The percentage of active coracidia developed from eggs taken from the fæces of dogs was only 1·5. Moreover, drying is found to destroy the embryo, which would still further reduce the significance of canine fæcal matter. These conclusions are confirmed by observation; for heavy infestation is associated not with the presence of dogs upon the shore, but with the discharge of raw sewage from communities where the habit of eating raw fish has been shown to persist. It would appear probable that the control of infestation is reasonably attainable, and that a major part of the programme of rational control would consist in chlorination of raw sewage from infested communities.

SANITARY DRINKING.

The Women's Bureau of the Department of Labour has just published a study of the laws governing the installation of drinking facilities and the present standards in 21 States. They feel justified in making this piece of public health research by the instruction received from Congress that they are to formulate standards to improve working conditions for women. After supplying ample evidence that a drinking fountain should have an inclined and not a vertical jet, and that the orifices of the jets must not be accessible to the mouths of drinkers, the Bureau's publication [1] shows that many old-fashioned insanitary types of drinking fountain are not only in use, but are still being installed. Among 1500 places of employment studied, only 4 per cent. had sanitary fountains for all their workers. Less than 15 per cent. had any drinking fountains of a satisfactory type. Investigation of the State laws shows that only 17 States definitely recommend that angle jet fountains be used in preference to the vertical jet type.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

THE TREATMENT OF PUERPERAL FEVER.

Dr. Ziegler reports the result obtained in the treatment of puerperal fever in the gynæcological department of the Virchow Hospital with a new compound, euthagen, said to be a silver salt of thiozellobiose. The special feature of that compound is that the silver salt when it comes into contact with the blood plasma is very slowly dissociated, so that it can act on the blood over a considerable time. The preparation was used in 44 cases, of which 5 died within the first five days; in 11 cases the septicæmia was complicated by endocarditis and peritonitis, and euthagen could not be expected to give good results. Eighteen of the remainder recovered, whilst in 10 cases the drug proved useless. The women when conveyed to the hospital had all had several rigors with very high temperatures, and were in a very bad condition. Intravenous injections of 5 c.cm. of a 5 per cent. solution of euthagen were given every other day. In some cases which were eventually cured 100, 80, and 60 c.cm. of the compound had been administered The injections produced neither pain nor thrombosis. The remedy appears to be worth a trial, since the results recorded above were obtained in patients who seemed to be in a desperate condition when they reached hospital.

THE EFFICACY OF MEAT INSPECTION.

The efficacy of meat inspection has recently been discussed in the lay press in connexion with an alleged increase of trichinosis in this country. Prof. Bongert, of the Berlin Veterinary College, stated, in reply to the attacks on meat inspection, that from 1925 to 1929 only 129 cases of trichinosis were notified in Germany with 16 deaths. In 1930 alone there were 95 cases with 11 deaths, the increase being due to an epidemic in Stuttgart traced to the consumption of bear-ham, which is not subject to inspection. During recent years 7,000,000 pigs had been inspected in Berlin by the Government meat inspectors; 70 of these were found to be infested, and might have caused epidemics if not condemned. Between 1905 and 1911 one pig out of 14,000 showed trichinæ, but in 1930 only one out of 67,000, notwithstanding the importation of foreign pigs. In cases where trichinosis has occurred after the consumption of pork it must have been due to a deficient inspection. The importation of tinned meat from abroad being illegal, the risk of disease from meat consumption is very small in this country.

EXAMINATION OF ICE-CREAM.

In the city of Magdeburg, paratyphoid fever having become rather prevalent, the ice-cream sold on the streets has been subjected to examination by the municipal health authorities. The head of the department concerned, Dr. Schäde, reports that 31 samples were received and showed from 1000 to 280,000 bacteria per c.cm. No paratyphoid bacilli were found, but only lactic acid bacilli, *Bacillus proteus*, and innocuous streptococci; in some samples *B. coli* was also present. The ice-cream was found to consist of milk, sugar, fruit juice, and owing to the large quantity of bacteria present fermentation took place at a temperature as low as 6–8° Centigrade. Dr. Schäde points out that of all countries Holland alone insists on the routine inspection of ice-cream. There no ice-cream may be sold having more than 100,000 bacteria per c.cm. He suggests that a similar law should be enforced in Germany.

LYMPHOGRANULOMATOSIS.

Attention is again being drawn to the morbid condition known as lymphogranulomatosis, described by Dr. Frey, on which I commented last year.[1] In the department for skin diseases of the Virchow Hospital 51 cases have been under the observation of Dr. Lobe and Dr. Blummer; in 49 of them the Frey test was positive. In the course of the illness a swelling of the inguinal and iliac glands develops.

---

[1] Correll, Marie: Sanitary Drinking Facilities, Bull. of Women's Bureau, No. 87. Washington, 1931. 10 cents.

[1] See THE LANCET, 1930, i., 937.

Lymphocytosis is a constant symptom. In many cases an exanthem in the form of urticaria or of a maculo-papular rash. The authors observed good results following intracutaneous injections of tuberculin. Operative removal of the glands takes a long time, the wounds healing badly, while radiotherapy gives no result.

MALARIAL INFECTION OF SYPHILITIC INFANT.

Dr. Schadow, of Hamburg, has recently described a case where a woman suffering from general paralysis treated by induced malaria gave birth to an infant in the eighth month of her pregnancy. No clinical symptoms of syphilis were present in the infant, but since the Wassermann reaction was positive the infant was treated with inunctions of mercury iodide ointment. Three weeks later pyrexia developed in form of tertian ague, the infant became gravely ill, the spleen being greatly enlarged. Examination of the blood showed a severe anæmia and the presence of malaria plasmodia. After administration of quinine and two transfusions of blood the infant recovered, and when seen after a year was strong and healthy.

THE ROBERT KOCH ANNIVERSARY.

In 1932 fifty years will have elapsed since Robert Koch discovered the tubercle bacillus, and plans are being made to celebrate his memory. The Robert Koch Fund for scientific research which had dwindled almost to extinction through the inflation of our currency will be revived. President Hindenburg has declared his readiness to become patron of the celebrations, which will take the form of a meeting at which foreign as well as German scientific men will be invited to deliver addresses, and the Chancellor will be honorary president.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

THE REGIUS CHAIR OF FORENSIC MEDICINE, GLASGOW.

THE resignation of Prof. John Glaister, M.D., Regius Professor of Forensic Medicine in the University of Glasgow, takes place on Sept. 30th. He has held the chair since 1898, having previously held a chair of medical jurisprudence and public health at St. Mungo's College, Glasgow. His whole life has thus been spent in the furtherance of medico-legal knowledge, and his classical text-book on the subject has reached a fourth edition. As medical referee for industrial diseases in six counties in Scotland, and as medico-legal examiner in Crown cases, Prof. Glaister has exercised a profound influence on the development of his subject, which extends throughout the British Empire. It is appropriate that the vacancy caused by his resignation, at the age of 75, should have been filled by the appointment of his son who has specialised on the same lines. John Glaister, jun., M.D., D.Sc., has been professor of forensic medicine in the University of Egypt, Cairo, and medico-legal adviser to the Egyptian Government since 1927. He qualified in 1916, and from 1916–19 served with the Royal Army Medical Corps. After the war he was appointed assistant to the professor of forensic medicine at Glasgow University. He qualified as barrister-at-law of the Inner Temple, London, and was called to the Bar in 1925.

Dr. Glaister has made numerous contributions to medico-legal literature, of which the most recent is a substantial work, published in Egypt this summer, entitled "A Study of Hairs and Wools." This book, which is profusely illustrated, embodies the results of his researches, extending over many years, on the medico-legal aspects of its subject.

A NEW HOSPITAL AT RHYNIE.

The late Dr. P. Nicoll, of Stratford, E., bequeathed £5000 for the establishment of a hospital for his native place, Rhynie, in North-west Aberdeenshire. The bequest was supplemented by gifts in money and kind, and the building was recently opened by the Duchess of Richmond and Gordon. It consists of four double and two single wards.

SUNDAY TENNIS IN HOSPITALS.

The resident medical staff at Stobhill Hospital, Glasgow, have asked permission to play tennis at that institution on Sundays after 2 P.M. The Glasgow Corporation Subcommittee on Institutions, by four votes to three, refused to recommend that the permission be granted, and the Health Committee finally refused the request by eleven votes to nine.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 29TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 33; scarlet fever, 1452; diphtheria, 750; enteric fever, 63; pneumonia, 341; puerperal fever, 31; puerperal pyrexia, 97; cerebro-spinal fever, 24; acute poliomyelitis, 14; acute polio-encephalitis, 1; encephalitis lethargica, 12; dysentery, 9; ophthalmia neonatorum, 122. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 1st–2nd was as follows: Small-pox, 33 under treatment, 2 under observation (last week 27 and 0 respectively); scarlet fever, 1091; diphtheria, 1351; enteric fever, 15; measles, 132; whooping-cough, 377; puerperal fever, 22 (plus 15 babies); encephalitis lethargica, 214; poliomyelitis, 8; "other diseases," 89. At St. Margaret's Hospital there were 16 babies (plus 10 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 6 (0) from measles, 1 (0) from scarlet fever, 19 (3) from whooping-cough, 30 (6) from diphtheria, 39 (9) from diarrhœa and enteritis under two years, and 15 (2) from influenza. The figures in parentheses are those for London itself.

Two deaths from whooping-cough were reported from each of Liverpool, Bradford, and Hull. Liverpool reported 9 fatal cases of diphtheria, Hull 2. Diarrhœa was credited with 5 deaths at Liverpool, 4 each at Nottingham and Leeds, 3 at Hull.

The number of stillbirths notified during the week was 205 (corresponding to a rate of 38 per 1000 births), including 49 in London.

KING GEORGE HOSPITAL CONTRIBUTORY SCHEME.—This new Ilford hospital is about to establish a contributory scheme on the basis of a weekly payment of 2*d*., supplemented by an employers' quota. The limits of the qualifying weekly income will be: single men or women, £4; married, without children, or with children over 16, £5; married, with children under 16, £6.

A NOISE SILENCER FOR HOSPITALS.—Several New York hospitals are said to be installing a new device for excluding noise which has been invented by Mr. Hiram Maxim. The apparatus consists of a box a foot wide and 10 inches high. It is placed on a window-sill and the window closed down to the top of the box, and although a large volume of air is admitted outside sounds are so completely excluded that even the noise of a pneumatic drill is unheard. The apparatus itself makes a noise comparable to that of an electric fan.

the medical staff of the Council under the direction of the principal medical officer may be called upon to serve any committee. A principal sister has administrative responsibilities over all the outdoor nursing staff of the corporation, including health visitors, home nurses, and school nurses. Towards the end of 1929 several school clinics were made available for pre-school children, and nursing and expectant mothers were admitted to the dental clinics. In the future a joint clinic at the Municipal Hospital at Southmead will serve as a centre for inspection and treatment of minor ailments of school-children and infants under 5; infant welfare clinics and a school for mothers; and antenatal clinics as well as dental, ophthalmic, and ear, nose and throat clinics. New developments in school work include the extension of the scheme for immunisation against diphtheria. Children are now inoculated in the schools instead of at the clinics. In March a clinic was opened at Southey House, College Green, for the investigation of "difficult children," and a certain number of delinquents has also been investigated. The clinic is under the direction of Dr. A. Dalby, who has the assistance of a school nurse for the investigation of environmental conditions; economic conditions have hitherto prevented development of this clinic along definite "child guidance" lines. The opening of the new Winford Hospital with 60 beds for prolonged treatment of cripples and heart disease has extended the good work being carried on under the rheumatic and orthopædic schemes. In nine years the number of cases of ringworm of the scalp have been reduced from 183 to 8 by the use of X rays, under the direction of Dr. F. C. Bergin. Major C. P. Rea, superintendent of physical instruction, regrets that no steps have yet been taken in private schools to bring the physical training more into line with the requirements in council schools. Children entering council schools after a period in private schools are often found to be handicapped through lack of knowledge and poor physique. The provision for exceptional children in Bristol is good, though accommodation for epileptics is, as elsewhere, difficult to find.

County of Nottingham.

Dr. C. Tibbits sets out the shortcomings of the school medical service in the county before chronicling the directions in which progress has been made. He admits, for example, that ascertainment of mental defect must be incomplete, since his service has found only 3 per 1000 of the children to be mentally defective, and it is improbable that Nottingham is particularly favoured in the mental capacity of its school population. Dr. Tibbits believes that in rural areas many cases of aural discharge remain untreated; special sessions in clinics, supplemented in rural areas by a travelling van, are needed. He regrets the lack of accommodation for epileptics, and for the delicate children who would benefit from education in the open air. The needs of the rheumatic child are not yet fully met. In other directions considerable advances have been made. All the treatment schemes are working well, the provision of spectacles having been facilitated, while the new complete dental scheme has been so keenly appreciated by parents that acceptances of treatment have risen to 65 per cent. A comparative table for Nottingham and for England and Wales shows how vigorously dental treatment is being tackled in this county. The scope of the dentist's work is to be increased by retaining in the scheme children whose parents previously refused treatment. An attempt to secure the routine medical inspection of pre-school children is being made. Valuable special inquiries include: a detailed analysis of the present conditions of 35 children who have received in-patient orthopædic treatment and have now left school; a record of the successful treatment of otorrhœa by flavine in glycerin, by Dr. C. W. Jeremiah; a record of the treatment of otorrhœa by ionisation, by Dr. J. Ferguson, whose results in certain cases are even more encouraging. Both authors point out that either of these newer methods is superior to the instillation of hydrogen peroxide.

City of Nottingham.

Dr. A. A. E. Newth says of developments in the school medical service that while some of them are intentional steps and others the results of the growth of scientific knowledge, many others are a response to the demands of teachers and parents.

"It is no part of our work to provide treatment that can be supplied more economically and efficiently by other activities, such as private practitioners and voluntary or public institutions. But where it is found that for various reasons—such as poverty, procrastination or indifference on the part of the parent, lack of accommodation in the homes or hospitals, or of the necessary medical organisation—this essential treatment is not otherwise obtainable, then it is our duty not only to ascertain the defects but to supply the remedies, and to follow up the cases afterwards to make sure that the treatment has been effective."

It is well that these facts should be recalled, since there are still some people who think that there is an inevitable opposition of interest, whereas in reality not only does the national health benefit but actually the increased attention drawn to health matters must lead the parents to seek more advice from their own doctors. The coöperation of all branches of the medical profession is for the good of all, and Dr. Newth specifically adds: "To an increasing extent the school medical service receives the courteous assistance and interest of private practitioners, and of the honorary and resident staffs of the hospitals and dispensaries. In this way the children are enabled to receive the fullest benefit from the medical facilities that are available." An outstanding feature of the past year was the opening of the Leen Side clinic to replace the old treatment centres at Hollowstone and Eastcroft. Of the cases summoned for examination by the surgeon-aurist, 82·3 per cent. attended, compared with 61·7 per cent. in 1929. Probably a factor in the popularity of this department is appreciation of the conservative methods of treatment adopted and of the critical attention given to each patient. Of the cases examined by Mr. H. B. Tawse, the surgeon-aurist, only about 50 per cent. were recommended for operation, the remainder were referred for further observation. Every child summoned for the first examination by the surgeon-aurist is now seen also by the dentist, and, if necessary, treated. The percentage of defects cured in the orthopædic department has greatly increased, while the period of treatment has been reduced. The effective method of dealing with ringworm has reduced the total loss of school attendance from 64,583 days in 1913 to 3678 days only last year. New fields of activity include the supervision of cases of rheumatism and heart disease under the general direction of Dr. J. W. Scott, as part-time consultant physician, and the examination of juvenile delinquents. The lack of a special school for physical defectives is one of the few gaps in a well-organised system; 461 cripples still attend ordinary elementary schools. Excellent features of this report are the section written by the organisers of physical training, a special record of an outbreak of diphtheria, with suggestions for control, and a brief, but judicial, account of some results of ultra-violet ray treatment by Dr. A. J. Davies.

THE SEAMEN'S HOSPITAL.—In 1930 there were 6576 in-patients and 26,167 out-patients; the income was £99,065, and the expenditure £106,241. The board has decided to provide a women's ward of 25 beds, and a children's ward of 20 beds in the Dreadnought, primarily for the dependents of sailors. The hospital will then be recognised by the General Nursing Council as a self-contained school for nurses who will no longer be obliged to take part of their training in a hospital for women and children; the length of their training will thus be reduced, by six months, to three years. The Seamen's Hospital Aid Committee has endowed a twelfth bed at the Dreadnought, making a complete ward.

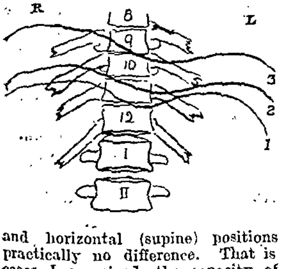
CORRESPONDENCE

THE LEVEL OF THE DIAPHRAGM.

To the Editor of THE LANCET.

SIR,—In my friend Sir Charlton Briscoe's interesting paper on the mechanism of the inflation of the lungs, in your last issue (p. 513), I note he still holds that when a subject lies down the diaphragm at once rises in the chest to such a degree that the respiratory capacity is materially decreased. On this belief he bases theories with which I am not concerned. I am however entirely convinced that this fundamental hypothesis is incorrect. As pointed out elsewhere (*Brit. Jour. Radiol.*, vol. iii., pp. 295–303, and vol. iv., p. 299), I maintain that the accepted teaching as to the behaviour of the diaphragm when a subject lies down is incorrect, in spite of the descriptions given in Gray's Anatomy (eighteenth ed., p. 442). Many observations, largely on healthy medical students, indicate that there is comparatively little change in the normal position of the diaphragm between the upright and horizontal positions. Nature provides an automatic compensatory mechanism so delicate that, even if we go to extremes and invert a subject head downwards, the diaphragm is found at approximately the same level.

In recording the position of the diaphragm it is essential for the X-ray tube to be accurately centred for each observation. Moreover skin marks are entirely untrustworthy, for when the recumbent posture is assumed, the skin moves very considerably in relation to the vertebral levels, even in thin subjects. On the anterior chest and abdominal walls this is well recognised, but it is not appreciated that a metal disc attached to the skin over the spinous processes of the vertebræ may be found fully one and a half inches higher in the recumbent than in the vertical position. Skin marks are therefore totally unreliable. Accurate records can only be obtained from radiograms showing the vertebræ. Records must not be made in the prone positions, for if the subject lies face downwards there is, of course, pressure on the abdomen and the diaphragm will, naturally, be found at an abnormally high level.



In the paper already quoted I reproduce tracings of the extremes of inspiration and expiration in the vertical and horizontal (supine) positions and there is practically no difference. That is to say, in the cases I examined, the capacity of the diaphragm to move was just as free in the horizontal as in the upright position. Moreover, the actual range, in relation to the vertebræ, was virtually identical. The accompanying Figure shows the diaphragm "at rest" in an average subject, a laboratory attendant 25 years of age, in its correct relationships to the vertebræ. The outlines are traced from radiograms in which the tube has been correctly centred and exposed in the mid-phase of respiration with the subject (1) standing, (2) lying supine, (3) lying prone. It will be noted that in the prone position (3), the diaphragm is very high in the chest, as high as in the maximum of forced expiration. In such circumstances, one would expect some embarrassment of respiration due to diminished capacity. It is due of course to the transmitted pressure on the diaphragm from the abdominal wall. Our own sensations tell what is happening, especially if we try lying face down after a heavy meal.

When we compare the ordinary positions of the diaphragm in the vertical and horizontal positions, (1) and (2), we note that there is approximately only half an inch difference and this is about the maximum that we find. Quite frequently no difference at all is noted. If, as Sir Charlton maintains, there is a marked diminution in the capacity of the lungs when the subject lies down, some other explanation of this contention must be found, for only a fractional part of it would appear to be due to the altered position of the diaphragm in the chest.

I am, Sir, yours faithfully,

Cambridge, Sept. 7th, 1931. A. E. BARCLAY.

DR. R. M. BUCHANAN'S WORK ON *BACILLUS TYPHOSUS.*

To the Editor of THE LANCET.

SIR,—To your obituary notice of my old friend, Dr. R. M. Buchanan (THE LANCET, August 29th, p. 509), I should like to add one interesting fact. Some 28 years ago, when the Local Government Board for Scotland was still in existence, and Dr. Russell was still its medical member, a sharp outbreak of enteric fever took place in Glasgow. It was traced to infected shell-fish from a west coast sea loch. This loch was known to be polluted by the sewage of a small town; but this town was a favourite resort of Glasgow trippers at the time of the fair, and, when the tide was down, there was a beautiful expanse of sand, where cockles and mussels were obtainable in marketable quantities. During the fair, there was a considerable amount of acute sickness (due to the shell-fish) at the little town; but the shell-fish sent to Glasgow was accused of originating typhoid fever in the city. I was medical inspector at the time, and Dr. Russell, who was a member of the Royal Commission on Sewage, thought that I might get some light for the Commission on the pollution of shell-fish. I was instructed to visit the place, and to see whether any materials could be found for further investigation.

Cockles were to be had in abundance out of a very grossly polluted area, and I procured, also, some specimens of a siphon-mussel known locally as "mushkin." I believe this was a variety of *Mya arenaria*. I did not verify the point; but the mussel buries itself below the sand, leaving the double siphon open. Several of these I gave to Dr. Buchanan to examine, along with cockles. In his report he gave a series of tests, and claimed to have isolated the *Bacillus typhosus* from one of those mussels. Dr. Russell had assured me that, up to that date, no one had actually found the bacillus in the shell-fish investigated for the Commission. I speak from memory, and, should I overstate, Sir Alexander Houston, who was bacteriologist to the Commission, will put me right. If Dr. Russell's assurance was correct, Dr. Buchanan must have been the first in this country to have demonstrated the presence of the typhoid bacillus in a mussel. So far as I can remember, he had failed to isolate the germ in any of the other shell-fish examined. The text-books tell us that the *Bacillus typhosus* does not survive long in sewage. If it survives at all, the mussels taken from the particular area would be almost sure to show it. I may add that the sewage of the town flowed direct on to the muddy and sandy shore, and included the sewage of a large asylum.

I am, Sir, yours faithfully,
W. LESLIE MACKENZIE.

Edinburgh, Sept. 3rd, 1931.

A REVOLVING SOLARIUM.

To the Editor of THE LANCET.

SIR,—Having recently visited Aix and been taken over the solarium by Dr. Jean Saidman, I was delighted to see Dr. Menko's letter describing it. Dr. Saidman tests every skin by means of a sensinometer and so avoids that erythema dose which is so common. The direct control and accuracy ensures correct dosage and the perpendicular action of the rays ensures penetration. Every patient's history and diagram of sensitisation is in front of the physician in charge. There is no guess work and no arbitrary timing for exposures. On leaving Aix I went to Cannes and Antibes where sun cures are in fashion. There the dosage is measured by how much exposure the bathers can stand lying on the beach and sitting on rocks. One had a vision of oiled backs, sore backs, and brown backs. The whole idea was wrong, but being a fashion, enjoyment was supposed to be obtained that way. I heard of not a few headaches and people who could not lie down in bed after the burning. If they had only known that browning after exposure protects the skin from penetration by the sun's rays, attempts to secure excessive browning in a short time would have gone out of fashion and the bathers have suffered less.

I am, Sir, yours faithfully,
LENNOX WAINWRIGHT.

Upper Wimpole-street, W., Sept. 7th, 1931.

PYREXIAL TREATMENT OF CHOREA.

To the Editor of THE LANCET.

SIR,—The recent work of L. P. Sutton to which you refer in an annotation last week (p. 545) raises a point of great interest. Of the value of heat-therapy in the treatment of chorea there can be no question. It is, however, permissible to criticise the method by which pyrexia is attained in her cases. In the frolic of unstable functions which characterises the choreic state the mechanism of heat-control and the skin take an important share. If the mouth temperature of the choreic child is taken at frequent intervals it will be found to be almost invariably low, while even more than in the healthy child is it disturbed by trivial causes. This thermal inefficiency and instability are associated with irregularity of sweat-secretion, the usual dry skin of the choreic child being prone to profuse and irregular sweating at night occasioned by trivial or hidden causes.

Probably the value of pyrexial treatment is to be ascribed to correction of this physiological failure of heat-control and to a stimulation of the skin and its sweat-glands. Chorea, in common with other rheumatic disorders, can unquestionably be cured by a combination of artificially induced fever and sweating, but some consideration of the child as an individual must guide us in the choice of the method by which these ends are to be attained. Hesitation must always be felt in giving daily intravenous injections to a child; when the child is nervous and choreic the method savours of brutality. A febrile reaction lasting six to seven hours is therapeutically desirable, but the method of its production appears indefensible. Equally good results can be obtained, though not so rapidly, by the daily use of hot packs or a vapour bath which will raise the temperature two or three degrees for one hour, promote free perspiration and induce mental calm and sleep.

This line of treatment has stood the test of experience and although a cure cannot be promised in eight to nine days as is claimed for the method advocated by Sutton, it can be looked forward to with confidence and without the possible harmful effects upon the mentality of an emotional child and the danger of physical harm resulting from the use of a vaccine between which and chorea no possible connexion can be claimed.

I am, Sir, yours faithfully,
CHARLES E. SUNDELL.

Queen Anne-street, W., Sept. 7th, 1931.

CRITERIA OF CURE IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I think Dr. Struthers is right (p. 530) to call in question the criterion of cure accepted by the Ministry of Health, on the validity of which his cases throw the gravest doubt—a criterion of cure which apparently they do not wish to accept for any figures but their own which show about a 3 per cent recovery-rate for an annual expenditure of about £10,000,000. I have been trying to get accepted as the official criterion of cure a test which has proved itself in cattle to be at the lowest estimate 95 per cent. correct on post-mortem examination, that is the subcutaneous test with a suitable and entirely innocuous dose of a potent tuberculin. A case which after treatment does not give a focal and general reaction may, for all practical purposes, be considered to be cured just as a cow which receives a subcutaneous injection of tuberculin is scientifically considered by every veterinary authority to be free from tuberculosis, that is, free from any lesion with live tubercle bacilli in it. I would therefore alter Dr. Struthers's last sentence to—Call no man cured of tuberculosis until he ceases to give the subcutaneous tuberculin test.

I am, Sir, yours faithfully,
W. M. CROFTON.

University College, Dublin, Sept. 5th, 1931.

BENDIEN'S WORK ON CANCER.

To the Editor of THE LANCET.

SIR,—As grave misconceptions have arisen as the result of the sensational writing up of a few minutes' telephone conversation by one of the Sunday papers, I should be very much obliged if you will let me make it perfectly clear that I have arranged with Dr. Bendien to carry out certain clinical tests of his work in my hospital practice. This work on my part is purely experimental, and I have no intention whatsoever of using it generally or in private cases unless, or until, I am completely satisfied as to its value.

I am, Sir, yours faithfully,
ROY R. KERR, F.R.C.S. Eng.

Manchester, Sept. 5th, 1931.

OBITUARY

NORMAN M. MacLEHOSE, M.B. Glasg.

Mr. Norman MacLehose, who died on August 30th, while on holiday in Ayrshire, was an ophthalmologist of distinction, although his name was never prominently before the medical profession or the public.

Born at Glasgow in January, 1859, Norman Macmillan was the youngest son of James MacLehose, printer and publisher. Educated at a private school, he entered Glasgow University, studying medicine under Sir William Gairdner and Sir Hector Cameron. After qualifying M.B., C.M.Glasg. in 1882 he held resident posts at the Western Infirmary and the Children's Hospital, and entered on general practice at Sevenoaks, before deciding to take up ophthalmology as a career. In 1885 he took the sanitary science certificate, the equivalent of the present D.P.H., at Cambridge, and spent several semesters in the ophthalmic clinics of Berlin and Vienna, returning to settle in London with a clinical assistantship at Moorfields Hospital. Election soon followed to a post on the staff of the Central London Ophthalmic Hospital, from which he retired as full surgeon in 1907. He joined the Ophthalmological Society of the United Kingdom in 1889, serving on its council from 1902 to 1905. At this time the literary bent which he inherited was seen in frequent contributions to the ophthalmic journals and, what was particularly congenial to him, in his work as editor of the *Ophthalmic Review* from 1891 to 1899. All these things were but the background to a private practice which was at one time very large and remained considerable until he retired from professional life in 1928. It has been said of this side of his work, with obvious truth, that no one who had once been in his hands ever willingly consulted another man. Although something of a recluse, he kept himself in touch with modern developments of ophthalmic medicine, and had a first-rate library on his specialty. For the rest he was widely read and keenly interested in many kinds of field sports, especially riding and fishing. When living at Berkhamsted, as he did before the war, he frequently rode to hounds.

Mr. MacLehose's home was in some ways a centre of books and book-lovers, for his wife was the second daughter of the publisher, Alexander Macmillan, and herself a woman of literary talents, for many years crippled by rheumatism. Their younger son fell in the war.

LOUIS SAMBON, M.D. Naples.

We regret to record the death of Dr. Louis Sambon, for many years known in connexion with various fields of research concerned with tropical medicine and the ætiology of malignant disease.

Louis Westenra Sambon was of mixed French and English lineage, his mother being a relation of Charles Dickens. He received his preliminary medical education at St. Bartholomew's Hospital, and he went to the University of Naples, his father, Commendatore Sambon, having Italian relations. There he graduated as M.D., and soon after graduation, in 1884, he was one of the medical officers to whom the dealing with an epidemic of cholera in the country was committed. For this work he received medals from both Italian and French Governments. In 1900, when the researches of Manson and Ross had revealed the history of malaria, Sambon and certain colleagues undertook individual inquiries into the occurrence of malaria in the Roman Campagna, where the disease was historically rife, and from this time forward he became an industrious student of tropical medicine, writing on the subject in many journals and lecturing in the London School of Hygiene and Tropical Medicine. One who had attended these lectures writes: "His popularity was seen in the crowded attendance at these lectures, which were patronised not only by students but by most of the teaching staff as well. Dr. Sambon's sense of humour and poetic methods of description brought forth constant applause from his audience."

Sambon's name is closely associated with long but inconclusive researches into pellagra. He studied the disease in Spain and Italy, and with Prof. Chalmers proved the existence of the disease in this country and Scotland. He wanted to make damaging criticisms of the maize theory of causation in the course of his studies, and substituted a parasitic theory, the parasite being spread by biting flies. With great industry he produced geographical and seasonal arguments in favour of the theory, but no parasite was found in definite association with the disease, while it was seen that a food deficiency theory need not rely upon the intake or otherwise of maize only. His later work was mainly directed to the discovery of the cause of cancer, and he expended much industry in the attempt to prove the parasitic nature of the disease. In support of the theory he made an intensive investigation in Italy, constructing maps intended to illustrate the distribution of cancer in that country. This work led him to conclude that sites of local infection existed, and he became convinced not only that areas of prevalence could be discovered, but that certain houses were the definite foci of infection. This was not a new theory, and statistical evidence was not forthcoming for it, while the connexion between these centres of infection and the presence of the vermin who, according to the theory, were the carriers, could not be established. He obtained, however, considerable support for his views, of the correctness of which he always remained certain.

His death occurred suddenly in Paris on August 31st.

THE LATE MR. PATTISON MUIR.

Many generations of doctors, who have graduated in the University of Cambridge, will join in regretting the death of Pattison Muir, the senior Fellow of Gonville and Caius College, who died on Sept. 2nd at the age of 82.

Matthew Moncrieff Pattison Muir's active connexion with medical education began when, after graduation at the University of Glasgow, he published with Prof. T. E. Thorpe notes on laboratory practice and qualitative analysis. This was in 1879. Then after post-graduate study at Tübingen, he began his long association with Caius College, where there was instituted a series of classes in chemistry designed to meet the needs of those working for the Natural Science Tripos and especially for the medical degree. The classes were not confined to Caius, and Muir attracted immediately a large number of students from all the colleges. He was the most sympathetic of teachers, betraying no impatience in the somewhat thankless task of instilling rudiments, but he was quick to detect those who responded intelligently to his instructions, and became at once their careful and interested guide in more advanced work. A large number of men will remember that they owe to Muir the encouragement which enabled them to make real progress in the science, and will recall his Scottish accents and his wistful manner, never more wistful than when it accompanied his witty sallies. His notes entitled "Chemistry for Medical Students" were used not only at the large medical school at Cambridge but by students of medicine at every university, and although he won his reputation as a scientific writer by more serious work, it is as the author of those notes that he will be most commonly remembered. In 1880 he was made an honorary M.A. of the University of Cambridge, and in the following year was elected a Fellow of Caius, where for more than 30 years he was Prælector in Chemistry. During this time he wrote a treatise on the Principles of Chemistry, which attained to a second edition, and collaborated with Dr. Charles Slater and with Dr. D. J. Carnegie in other text-books on the subject. In 1894 he became, in collaboration with Dr. Forster Morley, responsible for issuing a new edition of Watts's "Dictionary of Chemistry," and this was a valuable literary performance. The Dictionary had passed through many editions since its publication in 1868, requiring supplements which duly appeared, but by 1894 it required not only revision but largely rewriting. The new issue brought the immense subject up to date, while preserving the clear and readable form of the summaries. A second edition was brought out in 1914, and a third in 1927. The historical side of his science always attracted Muir, and he wrote in a fascinating way not only on the vicissitudes of chemical theories and laws, but on the influence of alchemy, these last studies taking shape in a work entitled "Roger Bacon: His Relations to Alchemy and Chemistry."

Pattison Muir retired from his post at Cambridge in 1910, and lived for a time at Norwich where he pursued his researches into the literary aspects of chemistry, and also became interested in the past intellectual activities of the cathedral city. On these subjects he became a much sought for lecturer, and his studies took shape in 1924 in a volume entitled "Men and Women of Letters in Norwich a Hundred Years Ago," which was of far more than local importance. The memory of Pattison Muir will long be preserved at Caius.

ALBERT EDWARD BRINDLEY, M.D.Lond., D.P.H.

Dr. Brindley, whose death occurred on August 21st at West Bridgford, near Nottingham, had but lately retired from the position of medical officer of health for the borough of Derby, which he had occupied for 22 years. Born at Astbury, Cheshire, in 1865, and educated at Congleton and Manchester Grammar Schools, Dr. Brindley entered Owens College, where he gained the Dauntesey medical scholarship, and later became an Associate. He took a science degree at Manchester in 1886, qualified there in medicine three years later, and went on to take the M.D. Lond. Having gained experience as resident at the Royal Infirmary, as a ship's surgeon, in private practice, and as head of a fever hospital, he became, in 1898, medical officer of health for Bury, until appointed to the post at Derby in 1907. Local health services in the town were then admittedly behind the times, and he set himself with characteristic energy to reorganise them almost single-handed. Shrewdness and determination overcame most of the difficulties, the Health Committee acquiescing even when they felt things were going a little fast for them. Maternity and tuberculosis services work were undertaken when still optional on a sanitary authority. Dr. Brindley was especially alive to the housing needs of Derby, and spent much time in solving the problem of crowded dwellings. In so doing he was greatly helped by the cordial relations which always existed between himself and the medical practitioners in the town. Since 1911 he had been lecturer and examiner in public health at the University of Manchester. Apart from his annual and special reports, which were always worth reading, he wrote a number of articles in public health journals on subjects such as housing, hygienic slaughtering of animals, and the control of tuberculosis.

Dr. Brindley was a keen Freemason, at one time a master of the local lodge at Bury; also for many years a member of the Derby Rotary Club. His retirement last April was the occasion of a presentation by members of the health department, who expressed appreciation of his services to the town and good wishes for his retirement. But his health was too far undermined by the stress of office. He leaves a wife, a son, and three daughters.

PARLIAMENT

THE PARLIAMENTARY SESSION.

THE Parliamentary Session opened with a full House on Tuesday last, Sept. 8th, and in an atmosphere which promised a division of main policy that is to be persevered in relentlessly by two parties. The Royal Message, asking that additional taxes should be instituted and economies effected, led to a general debate on the position. The Prime Minister explained that he had found it impossible to bring the late Government into accord with measures which were, he held, necessary to meet an urgent financial emergency, and Mr. Henderson, as leader of the Opposition, replied that he and his followers found the proposed cuts in social services to be unjustifiable. Mr. Baldwin said that the coöperation of the Conservatives in the task of balancing the Budget would be complete. The period for which the Government would function was discussed, and speakers on each side expressed opposite opinions on the cause and extent of the financial emergency, and therefore on the methods of remedy. The majority of the Government, 59, was understood to be a little larger than was anticipated.

MEDICAL NEWS

Research Fellowship in Radiology.

The British Empire Cancer Campaign has received a gift of £25,000 from Sir William Morris for the establishment of a research fellowship in radiology at Mount Vernon Hospital, Northwood. This hospital, which is now devoted to the investigation and treatment of cancer, is in acute financial distress, half of its beds having had to be closed through lack of funds.

Fellowship of Medicine and Post-Graduate Medical Association.

The following courses will take place shortly: medicine, surgery, and specialties at the Metropolitan Hospital, Kingsland-road, E., from Sept. 28th to Oct. 10th; a similar course at the Prince of Wales's Hospital, Tottenham, from Oct. 12th to 24th. Diseases of the throat, nose, and ear Hospital, at the Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, from Oct. 5th to Oct. 31st, and including a clinical course, a pathology class, a peroral endoscopy class, and an operative class; and tropical medicine at the Hospital for Tropical Diseases, 25, Gordon-street, from Oct. 5th to 24th. All these courses occupy the whole of each day. A course of lectures for the M.R.C.P. will be held at 8.30 P.M. at the Medical Society of London, 11, Chandos-street, Cavendish-square, on Mondays and Wednesdays beginning Oct. 5th. Further particulars are obtainable from the Fellowship of Medicine, 1, Wimpole-street, London, W. 1.

Hunterian Society.

The presidential address will be delivered by Dr. David Ross at a dinner meeting, to be held at Simpsons' Restaurant, Cheapside, London, E.C. 2, at 7.15 P.M., on Oct. 22nd. The next dinner meeting will be held at the same place and time on Dec. 17th, when Prof. John Eyre, Dr. W. S. C. Copeman, and Mr. C. R. Rudolf will open a discussion on Oral Sepsis. On Nov. 10th a meeting will be held at the Apothecaries' Hall, E.C., at 9 P.M., when a discussion on the Medical Aspects of Crime in Fact and Fiction will be opened by Dr. Norwood East, Dr. Edwin Smith, and Mr. C. J. S. Thompson.

British Science Guild.

The Alexander Pedler Lecture for 1931 will be delivered at 5.30 P.M. on Oct. 21st, under the joint auspices of the University of Durham Philosophical Society and the British Science Guild, at Armstrong College, Newcastle-on-Tyne, by Prof. Irvine Masson, D.Sc. The title of the lecture will be Problems in the Teaching of Science. The Norman Lockyer Lecture for 1931 will be delivered on Nov. 24th, at 4.30 P.M., in the Goldsmiths' Hall, London, E.C., by Dr. H. H. Dale, F.R.S.

Vacancies

For further information refer to the Advertisement columns.

Aberdeen Royal Infirmary.—Jun. Asst. Surgeon.

Aberdeen Woodend Municipal (General) Hospital.—Jun. Res. M.O. £100.

Accrington, Victoria Hospital.—H.S. £150.

Acton Borough Education Committee, W.—Asst. School M.O. and Asst. M.O.H. £550.

Altrincham General Hospital.—Jun. H.S. At rate of £120.

Ashton-under-Lyne, District Infirmary.—Res. Surg. O. £200.

Bedford County Hospital.—Asst. H.S. At rate of £130.

Birmingham and Midland Eye Hospital, Church-street.—H.S. £110.

Birmingham City Education Committee.—Special Schools M.O. and Director of Child Guidance Clinic, not exceeding £800. Also Two Asst. School M.O.'s Each £500.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Asst. M.O. £300.

Birmingham, Monyhull Colony.—Second Asst. M.O. £350.

Birmingham, Selly Oak Hospital.—Cas. O. At rate of £200.

Blackburn County Borough.—Asst. School M.O. and Asst. M.O.H. £700.

Brighton Sanatorium and Infectious Disease Hospital.—Jun. Res. M.O. At rate of £150.

Bristol Royal Infirmry.—H.P. Also Asst. H.S. Each at rate of £60.

Burnley County Borough.—Asst. M.O.H. and Asst. School M.O. £500.

Chester, Wrenbury Hall Tuberculosis Training Colony.—H.P. £250.

City of London Maternity Hospital, City-road, E.C.—Asst. Res. M.O. At rate of £80.

Connaught Hospital, Walthamstow, E.—Sen. Res. H.S. At rate of £150.

Derby County Mental Hospital, Mickleover.—Res. Jun. Asst. M.O. £350.

Derby, Derbyshire Hospital for Women, Friar Gate.—H.S. At rate of £150.

Dudley Guest Hospital.—H.S. £170–£200.

East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. At rate of £150. Also H.S. to Special Depts. and Cas. O. Each at rate of £120.

Great Yarmouth General Hospital.—H.S. £140.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Hammersmith Hospital, Ducane-road, W.—Asst. M.O. £350.

Hastings, Royal East Sussex Hospital.—Sen. H.S. At rate of £150.

Hereford County and City Mental Hospital.—Med. Supt. £600.

Hertford, Watford Maternity and Nursing Home.—Visiting M.O. £120.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. and H.P. Each at rate of £100.

Hull Royal Infirmary.—Hon. Asst. Physician.

Ilford, King George Hospital.—H.S. At rate of £100.

Kidderminster and District General Hospital.—H.S. £150.

King's College Hospital, Denmark Hill, S.E.—Hon. Anæsthetist.

Lingfield, Surrey, Epileptic Colony.—Asst. M.O. £275.

Liverpool Eye and Ear Infirmary, Myrtle-street.—H.S. to Ophth. Dept. £120.

Liverpool Royal Southern Hospital.—H.P., M.O. to Spec. Depts., and Res. Anæsthetist. All at rate of £60.

Liverpool, St. Paul's Eye Hospital, Old Hall-street.—H.S. At rate of £120.

London Female Lock Hospital, Harrow-road, W.—H.S. At rate of £150.

Longton Hospital, Staffs.—H.S. £150.

Macclesfield General Infirmary.—Sen. and Jun. Res. M.O.'s. At rate of £180 and £150 respectively.

Manchester, Ancoats Hospital.—Res. Surg. O. £200.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester, Royal Infirmary.—Jun. Asst. M.O. for Radiological Dept. £400.

Margate Royal Sea Bathing Hospital for Surgical Tuberculosis.—H.S. At rate of £200.

Miller General Hospital, Greenwich-road, S.E.—Hon. Gynæcologist. Also Cas. O. and H.P. At rate of £150 and £125 respectively.

National Hospital, Queen-square, W.C.—Asst. Registrar. £200.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Physician to Skin Dept.

Norwich, Norfolk and Norwich Hospital.—H.S. £120.

Portsmouth, Royal Portsmouth Hospital.—Cas. O. At rate of £100.

Princess Beatrice Hospital, 194, Finborough-road, S.W.—R.M.O.

Putney Hospital, Lower Common, Putney, S.W.—Res. M.O. At rate of £150.

Queen's Hospital for Children, Hackney-road, E.—H.P. At rate of £100.

Reading, Royal Berkshire Hospital.—Radiological H.S. and Res. Anæsthetist. At rate of £150.

Richmond, Surrey, Royal Hospital.—Hon. Surg. to Ear, Nose, and Throat Dept.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Eye Hospital, St. George's Circus, S.E.—Twelve salaried Refractionists, twelve Clin. Assts., and Pathologist.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Two H.S.'s Each at rate of £150. Also H.S. for County Branch, Brockley Hill, Stanmore. At rate of £150.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. At rate of £200. Also H.S. At rate of £100.

St. Giles Hospital, Brunswick-square, Camberwell, S.E.—Part-time Radiologist. At rate of £236 5s.

St. Mary's Hospital, W.—2nd Asst. Pathologist. £250. Also Obstetric Registrar. £50.

St. Thomas's Hospital, S.E.—Res. Asst. Surgeon. Also Surg. Reg.

Salford Royal Hospital.—Res. H.S.'s. to Special Depts. Also Cas. H.S. All at rate of £125.

Scarborough Hospital and Dispensary.—Two H.S.'s. Each at rate of £175.

Scotland, Department of Health.—M.O. £600.

Sheffield, Jessop Hospital for Women.—Sen. Res. M.O. £200. Also Res. M.O. and two Asst. H.S.'s. At rate of £150 and £100 respectively.

Sheffield Royal Hospital.—Ophth. H.S. Also Anæsthetist. £120 and £80 respectively.

Sheffield Royal Infirmary.—Asst. Aural and Ophth. H.S. and H.S. and Second Asst. Cas. O. Each at rate of £80.

Southampton County Borough.—Asst. M.O.H. £500.

Stafford, Staffordshire C.C. County Bacteriological Laboratory.—Asst. Bacteriologist and Pathologist. £700.

Stamford, Stamford, Rutland and General Infirmary.—H.S. At rate of £150.

Sutton and Cheam Hospital.—Res. M.O. At rate of £150.

Swansea, Infectious Diseases Hospital.—Res. M.O. £350.

Taunton, Taunton and Somerset Hospital.—Asst. H.S. At rate of £100.

Watford, Herts., Peace Memorial Hospital.—Res. and Surg. M.O.'s. Each at rate of £150.

Wells, Somerset, Mental Hospital.—Asst. M.O. £350.

West London Hospital, Hammersmith-road, W.—H.P., H.S.'s, and Res. Anæsthetist. All at rate of £100.

West Riding of Yorkshire County Council.—Temp. Sch. Med. Inspectors. £500.

Windsor, King Edward VII. Hospital.—H.S. At rate of £100.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E. Res. M.O. £175.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Milnthorpe (Westmorland), at Ulceby (Lincoln), and at Holt (Norfolk).

Births, Marriages, and Deaths

MARRIAGES.

Higgins—Hodgkinson.—On Sept. 3rd, at St. Philip's Church, Alderley Edge, James Basil Higgins, M.B., Ch.B. Vict., D.M.R.E. Camb., to Muriel Betty Hodgkinson, daughter of Mr. and Mrs. E. Nicholls Hodgkinson, of Wilmslow.

Satchwell—Jones.—On Sept. 1st, at Llanfyllin, Montgomeryshire, Hubert John Satchwell, M.B., Ch.B. Bristol, of North Curry, Somerset, to Mary Glennie Jones, M.B. Ch.B. Liverp., of Llanfyllin.

Tylor—Bazett.—On Sept. 3rd, at Totnes, Devon, Max F. Tylor, M.B., B.Ch. Oxf., of Dartmouth, to Christine Margaret Bazett, second daugher of Mr. Charles Bazett and the late Mrs. Bazett, of Victoria, British Columbia.

Walker—McCormick.—On Sept. 5th, at Holy Trinity Church, Brompton, Robert Milnes Walker, M.S. Lond., F.R.C.S. Eng., of Wolverhampton, to Grace Anna, eldest daughter of Dr. and Mrs. McCormick, of London.

DEATHS.

Barbour.—On August 31st, at Portsea-place, Hyde Park, W., James Barbour, M.D. Edin., in his 83rd year.

Blurton.—On Sept. 6th, suddenly, at West Bridgford, Nottingham, Gilbert Blurton, M.B., B.S. Lond., aged 39.

Harwood.—On August 31st, suddenly, in London, Thomas Eustace Harwood, M.B., Ch.B. Edin., aged 56.

Parr-Dudley.—On August 31st, at the Hospital, Maidstone, A. Dudley Parr-Dudley, Barrister-at-Law, M.R.C.S., L.R.C.P. Lond., of East Malling, Kent, formerly of Cossington, Leicestershire, aged 72.

Richards.—On Sept. 4th, Ramsey Martyn Richards, M.R.C.S. Eng., L.R.C.P. Lond., Surgeon Captain R.N., retired, of Betworth, Exmouth, aged 56.

Sambon.—On August 31st, suddenly, in Paris, Prof. Louis W Sambon, M.D. Naples, of Fordwych-road, London.

White.—On Sept. 3rd, at Weston-super-Mare, and late of Cambridge, Sidney Hugh White, M.R.C.S. Eng., L.R.C.P. Lond., Surgeon Captain R.A.M.C., aged 58.

Whitehead.—On Sept. 1st, at the London Hospital, Henry Edward Whitehead, M.R.C.S. Eng., L.R.C.P. Lond., of Caledonian-road, N., aged 69.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

BRITISH WATERWORKS.

We have received from the British Waterworks Association a copy of their Yearbook and Directory for 1930–31. This is the third edition of a reference book of great usefulness, edited by Mr. G. P. Warner Terry, barrister-at-law, which may be had for one guinea, post free, from the Secretary of the Association, 173, Rosebery-avenue, London, E.C. 1. The major part of the book consists of an alphabetical directory of waterworks throughout England and Wales, embodying replies to a questionaire, and containing information under headings such as Date of Establishment, Special Acts, Limits of Supply, Character of Water, Source of Supply, Service Reservoirs, Domestic Charges, and so forth. Following this is a series of statistical tables, also compiled from actual returns received. Table 4, which is of special interest, gives the average supply of water per day per head of population in the area, which varies from 10 gallons for West Mersea, and 11 gallons for Cardiff rural, up to 95 for Irvine, 108 for Burntisland, and 180 for Greenock, most of the large municipalities providing 25–35 gallons a head. The time is not far distant when water authorities may have to combine to consider, in the interests of municipal economy, what is the minimum amount of water which covers the whole demands of health and reasonable comfort. Since an inch of rainfall on an acre of land yields more than 22,000 gallons of water, it might be thought that some of these figures are stingy, but only a small proportion of this rainfall can ever reach the waterworks pumps, and it is not long ago that a general water shortage was feared. The twelfth annual report of the Ministry of Health admits that much remains to be done before the water supply in rural areas can be regarded as satisfactory, and alludes to the need of gauging rivers and underground waters.

ROYAL INSTITUTE OF PUBLIC HEALTH.

In addition to the places mentioned on page 495 of the Students' Guide (The Lancet, August 29th), courses of study for public health degrees and diplomas are offered in London by the Royal Institute of Public Health. The syllabus is covered by a teaching staff of nine under the headings Chemistry and Physics, Hygiene *Physiology and Physiotherapy*, Applied Bacteriology and Immunology, General Principles of Public Health, Epidemiology and Vital Statistics, Sanitary Law and Administration, Public Health Administration, Sanitary Construction and Planning, Port Sanitary Administration, Meat and Food Inspection. The course includes the practical work of a medical officer of health, visits to places of public health interest, and instruction in the selection of building sites, heating, lighting and ventilation of occupied premises, and so forth. There is a composition fee for the whole course, which can be commenced at any time. Particulars from the secretary at 37, Russell-square, London, W.C. 1.

THE BEAD TEST OF GASTRO-INTESTINAL FUNCTION.

Under the auspices of the French Government a group of American doctors recently visited the principal thermal and climatic resorts of France. The visitors included Dr. Max Einhorn, who gave a lecture at Vichy on the Bead Test (digestive test capsules). He explained that the method consisted in causing the patient to swallow a little capsule containing beads attached to a thread, each bead being covered with different types of food, to test the activity of the digestive process in the different parts of the intestinal tract. The food substances employed are catgut, fishbone—to test gastric digestive function—and meat, thymus, mutton fat, potato (with the peel)—to test intestinal digestive function. The capsule is swallowed after a meal, and the beads are evacuated per rectum, after a period which may indicate some degree of stasis or too rapid passage of foodstuffs through the intestinal canal. The beads are then gently washed in cold water, and examined, in order to ascertain the degree of digestion undergone by each of the nutritive substances which covered them. Dr. Einhorn said that the test had enabled him to classify gastro-intestinal dyspepsia into three categories: partial, total, and nervous dyspepsia, the latter being purely functional.

WALKING ON THE MOORS.

Mr. W. Ridley-Makepeace has followed up his little book on Goathland Walks by a further series of Walks and Talks on the North Yorkshire Coast and Moors. (London: A. Brown and Sons, Limited, 5, Farringdon-avenue, E.C. 4. Pp. 120. Price 1s.) He is a rambler of sixty years' standing, who desires to attract the north, south, and west to a part of England which he regards as the pedestrians' paradise. He describes and illustrates a series of eleven walks, with a wealth of interesting detail, historical and topographical. As a whole-hearted walker, he also devotes space to the dangers of motor-vehicle traffic, and to the slovenly and dirty habits of picnickers who leave their litter behind, quoting with approval Mr. F. A. Rush's lines which begin—"Why dost ta' throw thi rubbish here, Tha mucky lout?" and, with some change of vernacular, might be posted on every spot of open ground in the country. The booklet is made more valuable by a complete index.

COINING NEW WORDS.

To the Editor of The Lancet.

Sir,—New words are always being coined, and anybody may do so by design, native wit, or mere accident. The *Times* some time ago accidentally invented the word "carbarian" for barbarian. A policeman at Stratford police-court this week called a pillion rider on a bicycle (a female, but either sex could have been meant) a "pillionaire." Last week I read in a Paris journal of a Russian who had lost his right leg, and was described as "l'unijambiste." This word is new to me, and not in my up-to-date "Nouveau Petit Larousse," although "manchot" (estropié ou privé d'une main ou d'un bras) as applied to one-handed or one-armed is there. For "unijambiste" I suggest in English "one-legger."

I am, Sir, yours faithfully,

Sept. 5th, 1931. Blancus.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

Monday, Sept. 14th to Saturday, Sept. 19th.—Infants Hospital, Vincent-square, S.W. Post-graduate Course in Diseases of Infants. Every afternoon at 2 P.M.—Central London Ophthalmic Hospital, Judd-street, W.C. Course in Ophthalmology. Every afternoon. Demonstrations and lectures, and hospital practice. Fee £3 3s.—Westminster Hospital, S.W. Post-graduate Course in Medicine and Surgery and the Specialties. Men only. 10.30 A.M. to 5.30 P.M. daily. —Further particulars from the Fellowship of Medicine.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, London, W.C.

Friday, Sept. 18th.—4 P.M., Mr. A. Lowndes Yates: Incipient Deafness.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, Sept. 17th.—4.30 P.M., Dr. Browning Alexander: Visceroptosis.

ADDRESSES AND ORIGINAL ARTICLES

PRECANCEROUS LESIONS OF THE ALIMENTARY TRACT.*

BY MATTHEW J. STEWART, M.B. GLASG., F.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LEEDS.

LECTURE II.

Cholelithiasis and Cholecystitis.

THAT there is an intimate association between gall-stones and carcinoma of the biliary passages, especially the gall-bladder, has long been recognised, but much difference of opinion still exists as to the exact relation of cause and effect.

In a series of 43 cases of carcinoma of the gall-bladder seen in the post-mortem room at Leeds, there were 30 with gall-stones, 69·8 per cent., as compared with 16·4 per cent. in the control series (1031 gall-stone cases in 6284 autopsies †). The difference (53·4 ± 7·0 per cent.) is highly significant. Various authors record similar and even higher rates (69 to 100 per cent., Rolleston and McNee, 1929). In the Leeds series there were also 20 cases of carcinoma of the larger (extra-hepatic) bile-ducts, including 11 with cholelithiasis, 55 per cent. The difference between this figure and the control (38·6 ± 11·1 per cent.) is less striking, but still significant. In the statistics of other authors gall-stones have usually been present in about one-third of the cases (Rolleston and McNee).

The closeness of association of the two diseases is equally well brought out when the problem is approached from the opposite standpoint. In the Leeds series the incidence of carcinoma of the biliary tract in cases of cholelithiasis was 3·8 per cent. as compared with 0·4 per cent. in the controls, a difference (3·4 ± 0·59 per cent.) which is highly significant. Other authors give even higher figures for the malignant cases (4 to 14 per cent.).

Of the principal varieties of biliary calculi, multiple facetted, solitary cholesterol, mulberry and pigment stones, it is apparently the first which is most frequently encountered in association with local cancer. Unfortunately it has been found possible to classify with exactness barely one half our total cases of cholelithiasis (Table IX.).

TABLE IX.—*Relative Frequency of Multiple Facetted and Solitary Cholesterol Gall-stones in Cancer of the Biliary Tract.*

Types of stones.	6284 control cases (over 40).	63 cases of cancer of biliary tract.	Percentage difference.	Standard error of difference.	Statistical significance.
	With gall-stones.				
Multiple facetted .	202 (3·2 %)	15 (23·8 %)	20·6	5·37	+
Solitary cholesterol	176 (2·8 %)	3 (4·8 %)	2·0	2·10	–

This shows clearly that the association is with multiple facetted calculi. Solitary cholesterol stones do not occur with significantly greater frequency in cases of biliary tract cancer than in the controls. Now, it is well known that it is the multiple facetted and pigment calculi which are chiefly encountered in cases of cholecystitis, and there are good grounds for the belief that the inflammatory lesion antedates, and is causally related to, the other. The solitary cholesterol and mulberry stones are of metabolic origin, and, as Gross (1929) has clearly shown, are unassociated with definite inflammatory lesions of the gall-bladder. The most probable sequence of events would therefore appear to be cholecystitis, cholelithiasis, carcinoma. The gall-stones may well act in a dual capacity, on the one hand maintaining and increasing the inflammatory reaction, on the other exerting a directly carcinogenic effect, mechanical or chemical, on the surviving epithelium.

Experimental evidence that gall-stones are capable of inducing carcinoma of the gall-bladder has been provided by Leitch (1924), who inserted into the gall-bladder of a series of guinea-pigs human gall-stones, pebbles, and pilules of pitch and lanoline. In eight (five with gall-stones, two with pebbles, and one with pitch) an apparent adenocarcinoma developed after 5½ to 12 months. The tumours had not undergone metastasis, and were not flagrantly malignant of aspect, but they were definitely infiltrative, and had invaded the liver, diaphragm, and abdominal muscles. Leitch himself was satisfied as to their carcinomatous nature. In two of the positive animals sterile pebbles had been used, and Leitch was of opinion that the causative factor was physical trauma rather than chemical irritation.

Gastric Ulcer.

This continues to be a topic of perennial interest to physician and surgeon, pathologist and radiologist alike, and it cannot be said that we have yet got to the root of the problem. What are the chances of a chronic gastric ulcer becoming malignant? How may this transformation be detected at the earliest possible moment? How may a surgeon at the time of operation know whether a cratered lesion of the stomach is simple or malignant? By what histological criteria may the pathologist distinguish between a simple ulcer, an ulcerative cancer, and a *carcinoma ex ulcere*? These are some of the practical issues on which further illumination is required.

INDEPENDENT COEXISTENCE OF ULCER AND CANCER.

It is a rare event for a simple chronic ulcer and a carcinoma to occur independently in the same stomach. In a series of 366 operation specimens examined between Jan. 1st, 1921, and June 1st, 1931, there were but three instances, and in a still larger series from the post-mortem room the incidence was even less. In only one case, seen at autopsy, were the two lesions situated side by side. Their independence of each other was manifest, since they had obviously come together in consequence of the centrifugal spread of the carcinoma. The ulcer, a typical chronic lesion, was situated almost exactly on the middle of the lesser curvature, and had given rise to a moderate grade of organic hour-glass contraction. The new growth, an equally typical ulcerated carcinoma, was situated saddle-wise across the lesser curvature, and extended from the upper margin of the ulcer to the cardia. In the other instances the cancer occupied its more usual position at or near the pylorus, the ulcer being situated one or two inches higher up.

MORBID ANATOMY AND HISTOLOGY.

There are certain points in the structure and evolution of a chronic ulcer and of a primary carcinoma of the stomach which must be kept clearly in mind when considering the question of ulcer-cancer.

---

* The Croonian Lectures delivered before the Royal College of Physicians of London on June 4th, 9th, and 11th, 1931. Lecture I. appeared last week.

† Only cases 40 years of age and over are included.

(1) The great majority of chronic ulcers which have existed for any length of time (months or years) have completely breached the muscular coat over an area at least as large as the widest part of the crater itself. This gap is occupied, though at a lower level, by a typical mass of dense sclerotic tissue, covered on its interior aspect by a narrow zone of fibrinoid necrosis and a quantity of purulent exudate and necrotic debris. The muscular coat either terminates abruptly in the lateral walls of the crater, or turns upwards into the floor when contraction is taking place therein. In healing ulcers, or at any point in the margin where partial healing has occurred, the muscular coat and the muscularis mucosæ tend to blend with one another in a very characteristic fashion.

(2) When a chronic ulcer has healed, there is usually remarkably good regeneration of the mucous coat, together with some slight regeneration of the muscularis mucosæ. The most notable permanent changes are in the muscular coat, which is not regenerated. There is complete and permanent replacement of a considerable area of muscularis, the extent of which depends on the size and chronicity of the original ulcer, by dense collagenous scar tissue. At first the scarred area is broad and cellular, but with the passage of months and years it becomes excessively sclerotic, almost acellular, and comes to contain masses of elastic tissue which cause it to be yellow instead of white. In many scars a certain amount of epithelial displacement, so-called deep regenerative heteroptopia, is encountered, by which simple, newly formed glands grow downwards into the surface layers of scar tissue and into or even through the muscularis mucosæ at the margins. It is a benign, self-limiting process, and there is no evidence that it is a precursor of malignant disease.

(3) When a carcinoma arises in a chronic ulcer it does so in the margin, probably at one point only. As the tumour increases in size it tends to encircle the ulcer rather than to penetrate the sclerotic floor, while also growing outwards from it. Ultimately the crater becomes completely surrounded by growth, while the floor itself may be partially invaded.

Much of the difficulty in the pathological diagnosis of ulcer-cancer arises in cases of this kind. Where there is only a small focus of malignancy on one side of a chronic ulcer there can be no doubt as to the sequence of events. When a cratered lesion shows a typical central ulcer floor devoid of cancer cells, with a complete ring of carcinomatous tissue encircling it, the question is, can such a lesion be brought about by secondary peptic ulceration of a primary carcinoma? If the whole floor of the crater is covered by growth, it is necessary to know whether such an appearance can result from the cancerisation of an ulcer.

(4) Primary carcinoma, even when it has infiltrated the whole thickness of the stomach wall, tends to conservation of the muscular coat, in many cases of the muscularis mucosæ as well (Dible, 1924–25; Stewart, 1926, 1928, 1929). These structures are, in fact, often much hypertrophied, standing out prominently on section, and even in that very fibrous lesion, the leather-bottle stomach, bundles of unstriped muscle persist in the midst of the fibro-neoplastic tissue. When secondary peptic ulceration is superimposed, however, neoplastic and non-neoplastic tissue alike gives way before it, and a more or less deeply cratered lesion results. If in the floor of such an ulcer persisting bundles of unstriped muscle, however scanty, can be detected amongst the tumour tissue assuredly the lesion is primarily carcinomatous. If a continuous zone of carcinomatous tissue across the floor of the ulcer is supported by dense scar tissue devoid of muscle-fibres, it is practically impossible on anatomical grounds to come to a definite decision.

Other facts in the case must be taken into account, the exact site of the lesion, the results of previous gastric analysis, and, in particular, the clinical history. Just as difficult are the cases in which scattered carcinomatous foci are present throughout an otherwise typically ulcerous floor, or when only a small area of cancer-cell-free sclerosis is present in the midst of the carcinomatous tissue. Unless there is definite clinical support for a diagnosis of ulcer-cancer it is my practice not to include such cases in this group. I certainly think it is possible for carcinomatous tissue to grow inwards over the floor of a simple ulcer, replacing the inner more cellular layer of granulation tissue. It is much more difficult for the neoplasm to replace or even to permeate the densely sclerotic deeper layers. I have recently encountered a case in which a carcinoma of the greater curvature had extended round the walls of the stomach until its margins met on the lesser curvature just below the site of a previously existing scar, and it was interesting to notice how considerable a barrier this had interposed to the further upward extension of the growth at this point. Only a few islets of epithelial tissue, though these of some size, had succeeded in penetrating the sclerotic mass. No conclusive evidence is available, on the other hand, that peptic ulceration of a primary carcinoma is capable of producing a zone of cancer-cell-free fibrosis in the floor. Assuredly this process may lead to an extensive breach of the muscularis, and, as Newcomb (1930) has pointed out, the same is true, *mutatis mutandis*, for some ulcerated carcinomas of the large intestine. In 100 intestinal cancers examined by him, six showed absence of muscle in the base of the lesion, and four of these exhibited marked fibrosis as well. Dr. Newcomb has been good enough to show me some of these sections, and in none of them is there an area of *cancer-cell-free* fibrosis such as one finds in ulcer-cancer of the stomach. This is the salient point of my criteria, and I do not think that Newcomb's analogy in any way detracts from its value. There can be no doubt of the great importance of Turnbull and Newcomb's (1925) criterion of fusion of muscularis mucosæ and muscularis as evidence of pre-existing ulcer. My contention, however, is that if this sign is always insisted on a number of real ulcer-cancers will be wrongly classified as ulcerated carcinomas. Fusion of these layers is evidence of healing, and carcinoma can undoubtedly arise in ulcers where no indication of healing exists.

One other possibility must be mentioned, that peptic ulceration commencing in a carcinoma may spread thence to the adjacent healthy wall. In my series there are four such cases, but in none had the ulcerative process involved the muscular coat to any serious extent. Clinically, such cases would resemble primary carcinoma rather than ulcer-cancer.

TABLE X.—*Position of Chronic Ulcer, Ulcer-cancer, and Primary Cancer in a Series of 358 Operation Specimens.*

Site of lesion.	Chronic ulcer.	Ulcer-cancer.	Primary cancer.
Pyloric canal ..	15 (5·7 %)	5 (29 %)	71 (84·5 %)
Lesser curvature region	248 (94·3 %)	12 (71 %)	9 (10·7 %)
Rest of stomach ..	—	—	4 (4·8 %)
Total *lesions*, 364*	263	17†	84

* In three cases two chronic ulcers coexisted, and in three others there were independent ulcers and cancers.

† Four of these cases in which death followed partial gastrectomy are also included in Table XI.

SITE OF THE LESION.

The vast majority of chronic gastric ulcers, fully 80 per cent., are situated in the lesser curvature region, most of the remainder being at or near the pylorus. Carcinoma, on the other hand, commences in the pyloric region in about two-thirds of the cases. The site of ulcer-cancer, as one would expect, approximates to that of simple ulcer (Table X.).

It may be objected that this gives only a partial and inaccurate view of the position, since it omits all inoperable cases. This objection applies with any force only to cases of carcinoma, and much less forcibly to ulcer-cancer. Table XI. has therefore been compiled from autopsy material to give a truer picture.

TABLE XI.—*Position of Primary Carcinoma and of Ulcer-cancer of the Stomach in a Series of 279 Post-mortem Specimens.*

—	Primary carcinoma.	Ulcer-cancer.
Pyloric canal	145 (61·1%)*	10 (31%)
Lesser curvature region	18 (8·0%)	22 (69%)
Cardiac region	37 (16·4%)	—
Rest of organ	26 (11·5%)	—
Totals	226	32†
Whole organ (more or less) ..	21	—
	247	—

* Twenty-one cases in which the whole or almost the whole organ was involved are not included in estimating the percentage incidence.

† Four of these cases in which death resulted from partial gastrectomy are also included in the list of 17 ulcer-cancers shown in Table X.

The topographical distribution of ulcer-cancer here shown, approximating as it does much more closely to that of ulcer than to that of cancer, would seem to indicate that the criteria used in the diagnosis of ulcer-cancer are reasonably near the truth. Tables XII. and XIII. focus attention on the comparative frequency with which carcinoma arises in pre-existing ulcer in the two main sites.

TABLE XII.—*Position of Chronic Gastric Ulcer in Relation to the Subsequent Development of Ulcer-cancer. (277* Clinical Specimens.)*

—	Ulcers.	With cancer arising in them.	Incidence of cancer.
Pyloric canal	20	5	25·0%
Lesser curvature ..	260	12	4·6%
Total	280*	17	—

* In three cases two chronic ulcers coexisted.

TABLE XIII.—*Position of Gastric Carcinoma in Relation to Pre-existing Simple Ulcer. (101 Clinical Specimens.)*

—	Carcinomas.	Arising in ulcer.	Incidence.
Pyloric canal	76	5	6·6%
Lesser curvature region	21	12	57·1%
Rest of stomach ..	4	0	—

Orator (1925), whose figure for the incidence of cancer in ulcer is very similar to my own (5·1 per cent., as compared with 6·1 per cent.), gets fairly comparable figures to those shown in Table XII. (11 cases of cancer arising in 34 ulcers of the pyloric canal—33·2 per cent.; 6 cases in 300 lesser curve ulcers—2·0 per cent.).

The conclusions to be drawn from these figures—i.e., in partial gastrectomy material only—are (1) that out of every three carcinomas arising in the lesser curvature region one inch or more from the pylorus approximately two have had their origin in a pre-existing simple ulcer, and (2) that whereas only one lesser curve ulcer in 20 shows evidence of malignant transformation, one in every four of those situated in the pyloric canal shows this change. What is the explanation of this difference? Hurst (1929*a*) suggests with much cogency that the additional factor is friction. He points out that neither the fundus of the stomach (where cancer is extremely rare) nor the duodenal bulb (where it is unknown) is ever subjected to friction. It is only in the pyloric vestibule that definite churning movements occur. Friction, minimal in the body of the stomach, steadily increases in intensity as the pylorus is approached, owing to the increasing depth of the peristaltic waves. It is probably for this reason that primary ulcer in the pyloric canal, though of comparatively infrequent occurrence, is particularly liable to malignant transformation.

PERFORATION.

In primary carcinoma of the stomach, perforation, whether acute or subacute, is a comparatively rare event. It had occurred in 15 of 276 cases in my autopsy series (5·4 per cent.). Simple chronic ulcer, on the other hand, shows a high perforation rate, 85 out of 242 cases (35 per cent.). The figures for ulcer-cancer approximate closely to those of simple ulcer, 9 out of 28 cases (32 per cent.). Those who refuse to accept these as genuine examples of *carcinoma ex ulcere* may reasonably claim that they represent merely a special group of primary cancers in which secondary peptic ulceration is unusually far advanced. I prefer to regard these figures as further confirmation of the truth of my ulcer-cancer criteria.

GASTRIC ANALYSIS.

The typical case of primary carcinoma with a short history shows either achlorhydria or hypochlorhydria when investigated by the fractional test-meal method. Complete achlorhydria was present in 65 per cent. of 74 cases investigated by Hurst (1929*a*), and other authors give comparable figures. There is naturally much less available evidence in connexion with ulcer-cancer. In my series fractional test-meals had been carried out in only nine cases, but the results are striking. No fewer than six had a high normal or hyperchlorhydric curve. In Table XIV. the results are compared with those obtained in 54 cases of simple ulcer and 30 cases of primary carcinoma. In each a partial gastrectomy had been performed and the specimen submitted to careful microscopic examination.

TABLE XIV.—*Fractional Test-meal Results in a Series of Pathologically Verified Cases of Ulcer, Ulcer-cancer, and Cancer of the Stomach.*

—	Simple chronic ulcer (54 cases).			Ulcer-cancer (9 cases).			Primary cancer (30 cases).		
Achlorhydria ..	20%	3 (6%)		13%	0		80%	22(73%)	
Hypochlorhydria		7	94%		1	100%		2	27%
Normal		35			5			6	
Hyperchlorhydria		9			3			0	

These figures are few, but they suggest that in contradistinction to primary carcinoma a normal or hyperchlorhydric curve is the rule in ulcer-cancer as in ulcer. They may reasonably be regarded as affording further confirmation of the criteria of ulcer-cancer set forth above. There is, of course, an alternative hypothesis—that a certain small proportion of primary carcinomas arise in stomachs which still possess a normal or hypernormal secretion of free hydrochloric acid. Such carcinomas would be more likely than those associated with achlorhydria to undergo secondary peptic ulceration, with on the one hand an increased tendency to perforation, and on the other a liability to assume in time the characters here regarded as typical of ulcer-cancer.

CLINICAL HISTORY.

Most writers on this subject have emphasised the importance of the clinical history in confirming or otherwise the conclusions arrived at on anatomical grounds (Dible 1924–25). The discovery that a lesion, regarded on pathological ground as ulcer-cancer, has given rise to symptoms for a few months only, is liable to shake one's faith in the reliability of one's histological criteria. In my series only one such case occurs, and it must be remembered that chronic ulcers do occasionally form and persist with little or no clinical evidence of their presence. Table XV. presents an analysis of my clinical material to date.

TABLE XV.—*Duration of Symptoms at the Time of Operation in* (A) *Simple Chronic Ulcer,* (B) *Primary Carcinoma, and* (C) *Ulcer-cancer of the Stomach.*

Duration of symptoms.	Simple ulcer (218 cases).	Primary cancer (69 cases).	Ulcer-cancer (17 cases).
0–6 months	9 } 10 %	31 } 73 %	1 } 6 %
6 months–1 year ..	14	19	0
1–2 years	17	7	1
Over 2 years	178 (82 %)	12 (17 %)	15 (88 %)
„ 5 „	136 (62 %)	0	11 (65 %)
Average duration of symptoms	8 years	11 months	5¼ years

These figures I submit are strong evidence in support of the accuracy of one's anatomical criteria.

Hurst (1929*b*) and others have emphasised the fact that when a simple ulcer undergoes malignant degeneration there is not infrequently a definite change in the symptomatology. The pain becomes more severe and more persistent, it ceases to observe its former time-relation to the taking of food, coming on, as a rule, immediately after meals instead of after a constant interval, and remissions either do not occur or are much less complete than before. Hurst also stresses the importance of the persistence of occult blood in the stools in spite of the most rigid dietetic and medicinal treatment, and the fact that radiologically the ulcer-crater, while it may get smaller, never completely disappears, as it does in most cases of chronic ulcer when properly treated. I would add a further point. The presence of altered blood in all or most of the fractions of the Rehfuss test-meal is strongly suggestive of malignancy, and if encountered in a case with a long ulcer-history the possibility of malignant degeneration must at once be raised. In the nine ulcer-cancer cases in my series in which a fractional test-meal was done, blood was present in seven. This contrasts with the findings in simple chronic ulcer, where altered blood is rarely encountered in routine test-meal examinations.

FREQUENCY OF ULCER-CANCER.

It is impossible to say with any degree of certainty what proportion of chronic ulcers become malignant, but the number is probably small. Most chronic ulcers will heal if given a chance, and with the restoration of continuity of the stomach wall the chances of malignant metamorphosis become greatly reduced. The incidence of carcinoma in ulcers which have been removed surgically is not inconsiderable, in my series 17 in 277, or 6·1 per cent. It is clear from the frequency with which well-healed scars are encountered in the stomach that the actual proportion of chronic ulcers which become malignant must be much less than this. The importance of chronic ulcer as a precancerous condition is, however, more strikingly brought out by regarding the problem from the cancer point of view. Of 109 operation specimens of carcinoma of the stomach in my series 17, or 15·6 per cent., showed evidence of having originated in a pre-existing simple ulcer.

DIAGNOSIS OF ULCER-CANCER AT OPERATION.

This is likely to be excessively difficult. A pr operative diagnosis should be aimed at. It may b impossible to decide from inspection of the stomac in situ whether the lesion is a perfectly simple chroni ulcer or one in which malignant proliferation ha commenced. The physician, or possibly the physicia and surgeon in concert, should decide on clinica grounds what operative treatment if any is desirabl and this decision should only be modified by ver definite contra-indications presenting themselves a operation. It is equally difficult, in cases of obviou malignancy, to determine at operation whether o not this has originated in simple ulcer, but here th matter has become of academic interest only. I ulcer specimens which have been removed surgicall and in which the interior can be closely inspected i is often possible to form an opinion naked eye as t whether cancer is present or no. Early carcinom betrays itself by irregularity and nodulation of th margin. At the best such an opinion must b provisional and subject to revision on histologica examination. I must confess to having wrongl suspected the presence of cancer naked-eye mo often than I have failed to detect its presence.

Chronic Gastritis.

In the matter of chronic gastritis and cancer I must reserve judgment. Unfortunately most of my material was taken without having this question in view, and while it is possible to say that both in ulcer and in cancer well-marked chronic gastritic changes are common in the lesser curvature region—"pylorus gastritis" of Faber (1927)—I have found little evidence of a generalised gastritis of the cul-de-sac or greater curvature in either of these diseases. Hurst (1929*a*) has shown that the achlorhydria which exists in from 50 to 75 per cent. of cases of carcinoma of the stomach is almost certainly an antecedent condition and not the result of the malignant disease He has never seen a case in which free *hydrochloric* acid was present at an early stage and disappeared as the disease advanced, but he has seen three in which a test-meal was given both before and after the onset of malignant degeneration of ulcer. Hyperchlorhydria was present in two and a normal acid curve in the third. In each the degree of acidity was undiminished when the carcinoma had developed. He quotes two other cases in which achlorhydria existed at least three years before the discovery of inoperable carcinoma. On the other hand, I have seen a case in which there was hyperchlorhydria two years and six months before an exploratory laparotomy for ulcer-cancer, by which time there was achlorhydria except for 20° of free HCl in the half-hour fraction. The patient came to post-mortem a day or two later, having died from perforation of an ulcer-cancer of the upper part of the lesser curvature. There had been a history very suggestive of gastric ulcer extending over nearly 20 years.

Hurst is of opinion that the achlorhydria which ordinarily precedes and accompanies primary carcinoma is the result of long-standing chronic gastritis. Two things have to be taken into account: (1) a chronic gastritis of the pyloric and lesser curvature regions as an actual precancerous lesion, and (2) a pan-gastritis as the cause of the achlorhydria. In my experience a chronic gastritis of the lesser curvature and pyloric regions is very common in cases of gastric ulcer, less common in cases of carcinoma. The lesion varies greatly in severity, and passes through hypertrophic and atrophic stages. At first the stroma is merely overrun by inflammatory cells, lymphocytes and plasma cells particularly, especially in its superficial zone. Later this extends to the deeper parts of the mucosa and there is a notable increase in the amount of lymphoid tissue, both superficial and deep to the muscularis mucosæ. Still later there is atrophy of the secretory glands, which may go on to complete destruction, the mucosa then consisting merely of inflammatory stroma and lymphoid tissue with a covering of simple cubical or columnar epithelium. In a very few cases of this kind I have seen carcinoma arising, apparently as a widespread superficial change. A type of vegetative epithelium is sometimes seen in these cases which might well be regarded as precancerous. The cells and their nuclei are well-stained and the normal content of mucin, in small droplets, is partially or completely lacking. The contrast between this epithelium, which is usually though not invariably limited to the surface zones, and the rest of the epithelium is remarkable, and a point of particular interest is that these hyperplastic cells obviously resist post mortem peptic digestion much more strongly than the others. I believe this to be a real precancerous condition, but am unable to say how often it progresses to malignancy.

Pangastritis of any severity is, in my limited experience, uncommon in both ulcer and cancer. Even in cancer cases with achlorhydria very little change may be present in the mucosa of the greater curvature, the oxyntic cells being apparently well preserved.

Duodenal Ulcer.

Those who argue against a close association between gastric ulcer and cancer usually refer to the remarkable fact that whereas chronic duodenal ulcer is definitely more common than gastric, carcinoma arising within the duodenal bulb is almost unknown. On the other hand, since carcinoma of the stomach is itself a common disease and primary duodenal cancer extremely rare (Table XVI.), this can hardly be regarded as a valid argument.

TABLE XVI.—*Incidence of Primary Carcinoma of the Gastro-intestinal Tract in a Series of 12,800 Autopsies at all Ages (Leeds 1910–31).*

—	Cases.		Percentage Incidence.	
Stomach		322		2·5

Ileum	3			
Ampulla of Vater		4		0·031
Large intestine		473		3·7

The incidence of primary carcinoma of the duodenum in this series, 0·031 per cent., may be compared with the figure obtained by Jefferson (1916–17) from a large series of collected data, 43 cases in 109,201 autopsies (0·04 per cent.).

A more important point is the anatomical distribution of duodenal cancer itself. For this purpose it is usual to recognise three divisions of the duodenum, supra-ampullary, peri-ampullary and infra-ampullary (Fenwick, 1901). In most cases the tumour arises in the peri-ampullary zone, but it is then not always possible to determine whether it has had its origin in the duodenal mucosa or in the ampulla of Vater.

In the Leeds series (Table XVI.) there were four certainly arising in the ampulla, while of four apparently primary duodenal cancers three were peri-ampullary and one only supra-ampullary. The latter was situated 4 cm. from the pylorus—i.e., beyond the usual ulcer-bearing area. Fenwick (1901), in 51 cases of duodenal cancer, found 11 (21·5 per cent.) supra-ampullary, 29 (57 per cent.) peri-ampullary, and 7 (13·5 per cent.) infra-ampullary.[‡] In Geiser's series of 71 cases the distribution was 11 (15·5 per cent.), 51 (71·8 per cent.), and 9 (12·7 per cent.). Probably the lowest site of all is the duodenal bulb, the position in which chronic ulcers or their scars are most frequently encountered.

Jefferson (1916–17) has collected 31 cases of carcinoma regarded as arising in pre-existing duodenal ulcers or scars. They form a thoroughly unconvincing series, though it is just possible that a few of them may be authentic. In Jefferson's own case the tumour was *2·5 cm. from the* sphincter pylori, and there was no sign of ulcer at autopsy. However, a gastro-jejunostomy had been performed some three years or so before, when it was stated that a duodenal ulcer had been found.

Kettle (1930) has reported one of the most convincing examples of ulcer-cancer of the duodenum, yet even in it there are elements of doubt. The histological criteria seem to be beyond cavil. The floor of the lesion was composed of dense sclerotic tissue indistinguishable from that ordinarily seen in chronic duodenal ulcers, there was a wide breach in the muscular coat, occupied by the fibrous tissue above-mentioned, and some of the smaller arteries showed well-developed endarteritis. Carcinomatous tissue was present all round the margin and had slightly invaded the sclerotic floor. There was also some clinical evidence, though not conclusive, of long-standing ulceration. Against ulcer-cancer was the position of the lesion at the junction of the first and second portions of the duodenum 4·5 cm. from the pylorus. Cases of chronic ulcer have certainly been reported in this situation, but they must be extremely rare. In my post-mortem series of 475 chronic lesions of the duodenum, ulcers and scars, all were within the duodenal bulb and not more than 2·5 cm. from the pylorus.

In 15 cases of duodenal carcinoma reported from the Mayo Clinic by Eusterman, Berkman, and Swan (1925), six were supra-ampullary, and in one the tumour was related to the scar of a healed duodenal ulcer.

Bearing in mind the great frequency of chronic ulceration and scarring in this situation it is a justifiable conclusion from a review of the literature that chronic duodenal ulcer is not a precancerous condition.

Diverticulitis.

The frequency and clinical importance of diverticulosis and diverticulitis of the large intestine have only been established in recent years. A very complete and detailed study of the clinical and pathological aspects of the condition was published by Telling and Gruner in 1917 and much admirable work has since been done on the radiological aspect by Spriggs and Marxer (1925) and many others. The condition of multiple diverticula or diverticulosis is a common one. It occurred in 158 of 1901 consecutive patients examined radiologically by Spriggs (1927)—8·3 per cent. Diverticulitis was present in only 17 of these—12 per cent. In 160 cases of diverticulosis examined in the post-mortem room at Leeds 23 (14 per cent.) had diverticulitis.

The occurrence of carcinoma in association with diverticula or diverticulitis was first reported by Hochenegg (1902), and since then scattered case-reports have made their appearance in the literature. Wilson (1911) reported four instances in 15 cases of diverticulosis operated on at the Mayo Clinic, and concluded that this was a definitely precancerous condition. He believed that the malignant changes arose in islets of epithelium segregated by the diverticular and peridiverticular inflammation. Telling and Gruner, who found 11 instances of carcinoma in a collected series of 324 cases of diverticulosis, took a similar view. The Mayo Clinic material has recently been reviewed by Rankin and Brown (1930), who found diverticulosis in 5 per cent. of all persons with large bowel symptoms and estimate the probable frequency in all persons at 1 per cent. Diverticulitis probably existed in 17 per cent. of the cases with diverticulosis. In 227 cases of *diverticulitis* requiring surgical treatment, cancer coexisted in four. In another series of 670 cases operated on for carcinoma of the bowel there were four with *diverticulosis*. They conclude that the relationship is incidental rather than significant.

My own more limited experience supports Rankin and Brown's view. In 160 cases of diverticulosis of the large intestine there were six with carcinoma coli, but of these only three were situated in the diverticula-bearing region. Twenty-three of the 160 cases were the seat of inflammatory changes, but only one of the six cases of malignant disease occurred in this group and there was nothing to suggest that it was of diverticular origin. In a discussion following a paper on diverticulitis and cancer by D. F. Jones (1930) Fallon mentioned that in a review of the Mayo Clinic records, including 1800 cases of diverticulosis, of which 625 showed diverticulitis and 19 carcinoma, and 1600 cases of carcinoma coli, of which 19 showed evidence of previous diverticulitis, he found only one case in which there was reasonable evidence that the carcinoma had arisen in a diverticulum. It may be concluded that diverticulitis is of no practical importance as a precancerous condition.

[‡] In the remaining 8 per cent. the disease involved the whole or greater part of the duodenum.

CARCINOID TUMOUR OF THE APPENDIX AND SMALL INTESTINE.

The appendix shares with the small intestine a remarkable immunity from the ordinary varieties of epithelial cancer, contrasting in this respect with the stomach and large intestine. In the appendix the neoplasm most frequently encountered, though even this is rare, is the well-known carcinoid tumour (Oberndorfer, 1907), now recognised (Gosset and Masson 1914, Masson 1924, 1928) to be a derivative of the neurogenous Kultschitzky cells which line the bottom of the crypts of Lieberkühn. These cells, of endodermal origin, bud outwards and invade the periglandular and subglandular nerve plexuses of the mucosa stimulating them to neuromatous overgrowth, a process most likely to happen in organs already the seat of an old obliterative inflammatory lesion.

Carcinoid tumours arise by neoplastic proliferation of these invading "neurocrine" cells, which, at first confined within the nerve sheaths, presently burst out into the connective tissue of the submucosa and invade the muscular coats. It is a slowly growing tumour of epithelial type, resembling in many respects the basal-cell carcinoma of the skin. It rarely disseminates to the regional lymph glands, and still more rarely to the liver or other organs (Stewart and Taylor, 1926). Its most frequent site is at the tip of the appendix. In the small intestine, where it occurs but rarely, it is usually multiple.

The association with old inflammatory disease of the appendix is well established (Kennedy 1909, 1910; Oberndorfer 1928), the tumour apparently arising in segregated portions of the mucous membrane which have had their continuity with the rest of the lumen and with the intestine interrupted by obliterative fibrosis.

So far as the small intestine is concerned no antecedent inflammatory lesion has been described. Those interested may be referred to the comprehensive studies of Masson (1924, 1928) and Forbus (1925).

AN OUTBREAK OF RABIES IN TRINIDAD

WITHOUT HISTORY OF BITES, AND WITH THE SYMPTOMS OF ACUTE ASCENDING MYELITIS.

BY E. WESTON HURST, B.Sc., M.D. BIRM.,
PATHOLOGIST TO THE MILBANK RESEARCH FUND, LISTER INSTITUTE, LONDON;
AND
J. L. PAWAN, M.B. EDIN., D.P.H.,
GOVERNMENT BACTERIOLOGIST, TRINIDAD.

RECORDS of rabies are of the greatest antiquity, dating back to the fifth century B.C. Though until comparatively recently it was believed that in the dog and wolf the contagium arose de novo, from the time of Aristotle onwards the human disease has always been associated with the bite of a rabid animal. While, for various reasons, in isolated cases no history of trauma may be available, an outbreak such as the present, in which no history of bites can be elicited, has never been described, and no other mode of transmission is recognised. Again, while paralytic rabies is not uncommon, an epidemic consisting solely of cases of the paralytic type is unprecedented. The facts we are about to record will, therefore, prove of interest alike to the neurologist, the epidemiologist, and the student of filterable viruses.

Description of the Epidemic.

EPIDEMIOLOGY.

History.—In July, 1929, there occurred in the village of Siparia in south-western Trinidad a case of acute ascending myelitis; this was followed within three months—i.e., during the rainy season—by 12 others. In the opinion of the local medical practitioners the cases constituted a distinctly unusual clinical entity. During the period July–August, 1930, three further cases were observed, and one early in 1931, when Sir Wilfred Beveridge visited the island on behalf of the Colonial Office. All 17 cases terminated fatally. At first localised to Siparia and its neighbourhood, the disease later spread further north towards the oilfield area.

Race.—The disease was confined to natives of the labouring class, who walk with bare feet. Well-to-do natives and Europeans have so far been unaffected. Of the 17 cases, three were members of the East Indian race, the others Negroes or descendants of Negroes.

Age and sex.—The age-incidence is interesting and is shown below:—

1929.		1930–31.	
0–5 years	1		
6–10 ,,	4	6–10 years	1
11–15 ,,	3	11–15 ,,	1
16–20 ,,	2	30–35 ,,	1
26–30 ,,	3	36–40 ,,	1

It is to be noted that in the 1929 cases a large proportion were in children of school age (the first two

cases occurred in the same school), and that the disease was not uniformly spread over the various age periods. Eleven males were affected and six females. In two instances more than one case occurred in a single household; in one the illness of a lad of 15 (still attending school on account of backwardness) was followed by that of his father, and the eighth case was a sister of the first.

Animal morbidity.—During the period covered by the present epidemic, the only disease prevalent among animals was one diagnosed as botulism in cattle, horses, donkeys, and mules; this will be dealt with later. With this exception, no undue prevalence of disease in wild or domestic animals has been noted during the last six years, though the inquiry respecting animal morbidity extended even to the mongoose and vampire bat. No case of rabies has been recognised since 1914. Quarantine laws are of the strictest and, except for animals coming from the United Kingdom, no dog can enter the island without a quarantine of at least six months and inspection and certification by the Government veterinary surgeon. In no instance was there history of a bite, nor on admission to hospital was there any evidence of injury.

The possibility of transmission by biting flies and insects was also considered, but with similar negative results. The mosquito and stomoxys fly are not more prevalent in the district affected than in other parts of the island.

Every case on notification was immediately removed to hospital and isolated. The premises were disinfected and the schools closed.

CLINICAL FEATURES.

From a clinical standpoint the cases formed a fairly homogeneous group with the characteristic and definite symptomatology of an ascending myelitis. Until experimental investigations were made, the outbreak was considered by some practitioners as probably one of acute poliomyelitis; this was rendered more likely by the fact that in the earlier cases no sensory changes were detected.

The onset was usually acute with fever and often headache. In many cases symptoms began with a sensation of burning and tingling, usually in the foot or leg, but sometimes in the back, and curiously enough nearly always on the left side; in some, retention of urine or paresis of the legs was the first sign. After one to four days, weakness of the leg became apparent, and developed more or less rapidly into complete paralysis, with loss of the tendon and plantar reflexes. The other limb and the trunk muscles were soon affected. Retention or incontinence of urine and constipation were present in every case. One to several days later, extension of the paralysis to the muscles of deglutition and respiration led to increasing difficulty in swallowing, dyspnœa, extreme restlessness, and invariable death. In some cases paralysis of the arms preceded the fatal termination, but in others considerable power still remained at the time of failure of respiration. Sensory changes appear to have been of variable occurrence; in only some of the patients was a loss of sensation to touch, pinprick, and heat and cold reported to extend upwards to the level of the pelvis, umbilicus, or lower ribs. Except for periods of delirium, the sufferers usually retained consciousness, and could answer questions intelligently until the end; in a few cases, however, drowsiness marked the middle stages of the illness, and at the close the patient was unconscious.

A swinging temperature varying from normal to 103° F. or higher was accompanied by profuse sweating, which was a very marked feature in nearly every case; as a terminal event the temperature sometimes rose to 104° F. or higher. As a rule the pulse and respiration increased in rate progressively as the state of the patient worsened. There was no nausea, vomiting, or cutaneous eruption.

It must be emphasised that difficulty in swallowing, associated in some cases with dribbling of saliva, occurred only in the terminal stages when paralysis of the bulbar muscles was obvious; hydrophobic symptoms were never present in the early stages. In Case 2 alone (see below) did spasmodic difficulty in swallowing during the later stages suggest to the doctor in attendance that the case "looked like one of hydrophobia." General muscular spasm was absent during the whole course of the illness; in several cases, however, stiffness of the neck was observed. Nervous symptoms were never preceded by a stage of excitement. At the height of the disease the cases had the anxious facies seen before the crisis in pneumonia, but clinically and post mortem the lungs were normal. Death was due primarily to respiratory failure and not to syncope.

With the exception of ptosis in one case, ocular paralyses were absent, as was optic neuritis in the patients examined from this point of view.

Examination of the blood and urine was always negative; no malarial parasite was found. Lumbar puncture was performed in five cases. The cerebrospinal fluid was perfectly clear and not under pressure; examination showed increase of globulin and contaminating organisms, but no cells. Circumstances, however, did not permit examination until about 12 or 16 hours after removal. Bacteriological investigation of throat and nasal swabs threw no light on the causation of the malady.

In 13 cases the duration of the illness was from four to eight days. One case died on the 3rd, one on the 10th, one on the 21st, and one on the 30th day.

The histories of the cases on which experimental work was carried out are set forth below.

CASE 1.—Female Negro labourer, aged 28, well-nourished and well-developed. Admitted August 20th, 1930, with a four days' history of pain and burning in the left foot.—August 21st. Numbness of left leg with absent knee-jerks and some loss of sensation in the foot.—August 22nd. Both legs weak, but patient still able to extend and flex at the knees and hips. Loss of sensation of left foot as far as ankle. Profuse sweating. Lumbar puncture yielded a slightly turbid fluid under moderate pressure, and showing, 12 hours later, some increase of globulin but no cells.—August 23rd. Weakness more marked and sensation lost in both legs as far upwards as the middle of the calves. 9 P.M. Complete paralysis of both legs with loss of sensation to the hips. Patient restless and sweating profusely. Periods of delirium, but questions answered rationally. Catheterisation necessary.—August 24th. Bladder and abdomen distended. Paresis of arms now apparent. Difficulty in swallowing. Dyspnœa. Loss of sensation to umbilicus. Death at 7 P.M.

CASE 2.—Female Negro schoolgirl, aged 10. Admitted to hospital Jan. 24th, 1931, with two days' history of fever, pains in the right lower limb, and difficulty in micturition. On admission she complained of pain in the right lumbar region radiating to the thigh and iliac fossa. Temperature, 99.8° F; pulse-rate, 112; respiration, 24. No weakness of limbs and no sensory loss. No retention of urine. Condition remained unchanged during next day.—Jan. 26th. Rapidly developed flaccid paralysis of lower limbs, with loss of sensation and incontinence of urine. Tendon reflexes abolished.—Jan. 27th. Temperature, 100° F.; pulse-rate, 136; respiration, 24. Profuse sweating. Weakness of arms with marked dyspnœa and difficulty in swallowing; the medical attendant thought that patient looked like a case of hydrophobia. Complete paralysis with loss of sensation in legs. Incontinence of urine. At 4 P.M. dyspnœa became worse, and inability to swallow was absolute. Profuse sweating continued. Lumbar puncture yielded a clear fluid under moderate pressure; 16 hours later no cells were seen. Death at 7 P.M.

POST-MORTEM FINDINGS.

The meninges over the brain and cord were congested, but no purulent exudate was present. In cases dying after three or four days the cord was of normal consistency, but the cross-section showed congestion and loss of demarcation between the grey and the white matter. In those succumbing after seven or more days the cord was much softer than normal, and in the lumbar region was often almost diffluent; these observations were made within a few hours of death, and were, in consequence, not attributable to post-mortem degeneration.

Except for congestion the other organs showed little departure from normal; in the heart, however, petechial hæmorrhages occurred with some frequency, especially along the line of junction between auricles and ventricles.

Material sent from Trinidad for histological study unfortunately miscarried, and at the time of writing only a single section from Case 1 and a piece of cord from Case 2, preserved in glycerin and fixed later in formol-saline, are available for section.

The section from Case 1 shows in both grey and white matter marked perivascular infiltration with large and small lymphocytes, a few large mononuclears and occasional polymorphs. There is diffuse infiltration of the grey matter with proliferated microglial cells and a few lymphocytes and polymorphs. Many of the anterior horn cells are well preserved, but some show complete chromatolysis, and others marked degenerative changes accompanied by neuronophagia. From this single section it is impossible to draw definite conclusions, as the appearances are compatible with a diagnosis either of poliomyelitis or of rabies.

In the second case the dorsal cord shows only occasional slight cuffing of the vessels, and most of the nerve-cells are normal. A few Babes nodules are present. No Negri bodies are to be seen. The appearances here are in keeping with a diagnosis of rabies.

Experimental Investigation.

Pieces of spinal cord from Case 1 and of a number of regions of the central nervous system from Case 2 were placed in sterile glycerin and forwarded to the Lister Institute.

Since, from the data available at the time, it was considered likely that the disease was poliomyelitis, the spinal cord of the first case was inoculated in doses of 1 or 2 c.cm. of a 10 per cent. emulsion in sterile saline into the left parieto-occipital lobe of each of four monkeys (*Macacus rhesus*). After incubation periods of 15, 17, 17, and 42 days respectively, the animals developed rather curious symptoms less characteristic of rabies than those observed later in passage animals. The following protocol is typical of three of the cases.

M.420. Received Nov. 25th, 1930, 2 c.cm. of a 10 per cent. spinal cord emulsion in the left parieto-occipital lobe.—Dec. 10th. Found clinging to the bars of its cage uttering repeated and peculiarly piercing shrieks quite unlike the normal cry of the monkey. These cries were emitted only during observation, and on withdrawal of the observer they ceased; the animal appeared to be in a state of extreme terror. It showed a disinclination to move, but when pushed off the bars of its cage its movements were quite active.—Dec. 13th. The animal now squealed continually, whether observed or not. It appeared to be generally weak, but no definite localised paresis could be detected. No muscular spasms were observed. The previous day's food had been left untouched.—Dec. 15th. The monkey had a staring gaze, and seemed unaware of the presence of food, of its cage-mate, or of the observer. It squealed continually, and the cries were much weaker than before. On interference it did not attempt to bite. The chin was abraded from constant picking with the fingers. Muscular spasms did not occur and no definite paralysis or rigidity was present. The animal was very emaciated, with a subnormal temperature, and as it seemed unlikely to survive until next day it was etherised.

The fourth animal behaved otherwise

M.444. Received Nov. 25th, 1930, 2 c.cm. of a 10 per cent. emulsion in the left parieto-occipital lobe and 3 c.cm. intramuscularly.—Dec. 12th. The animal showed some tendency to squeal like the others, but, from the first, localised weakness was apparent in the legs. During the next few days it gradually became more sleepy.—Dec. 16th. Paresis of the legs was now marked. The monkey lay apparently asleep on the floor of its cage, and though it could be momentarily roused it immediately lapsed into somnolence.—Dec. 17th. The animal was very sleepy, and completely apathetic, even to painful stimuli. Flaccid paralysis was present in the legs. In the arms, which fell limply to the side when released, considerable power still persisted, so that the apparent weakness seemed due to the animal's mental condition. Thus after repeated stimulation it could be induced to grasp the observer's finger; when suspended in the air the animal once more lapsed into somnolence, its grip gradually relaxed, and eventually it fell to the ground. No muscular spasms occurred. Later in the day the temperature was subnormal, and the animal was etherised.

At *autopsy*, definite macroscopic changes were noted only in M.444, which showed several hæmorrhagic areas in the lungs and intestines. Cultures, aerobic and anaerobic, from the brains of all four animals remained sterile for ten days.

In animals inoculated from the above, the symptoms were typical of rabies, and very similar to those in a monkey infected with the *virus fixe*. After a short period, in which the animal was actively aggressive, and in one case killed its cage-mate, violent muscular spasms, occasionally sufficient to throw the animal bodily across the cage, occurred and gradually passed into a stage of general weakness ending in death. In different cases one or other of these manifestations predominated; convulsions might persist almost to the end or, from a very early stage, great general weakness, associated once with definite paralysis of the legs, might be the most conspicuous feature. In some cases nystagmoid movements of the eyes were observed, and the animal nearly always wore a dazed expression. Three animals bit themselves severely, two chewing off the end of a finger, and one the whole skin of the forearm, exposing the muscles from the elbow to the wrist. The onset of symptoms was sometimes heralded on the preceding day by a rise of temperature, but more often no temperature disturbance was noted. The incubation period varied between 6 and 11 days, and was commonly 7 to 9 days; death frequently occurred within 12 hours, and always within 48 hours of the first symptom. The disease has now been transmitted to five generations of monkeys by intracerebral or intraneural inoculation; unfiltered emulsions and Chamberland LI *bis* filtrates have alike been effective.

Some difficulty was experienced in establishing the original monkey virus in rabbits, and at first it could not be taken past the first or second passage, but ultimately by choice of suitable animals the seventh generation was reached. The symptoms were typical of paralytic rabies, and indistinguishable from those due to the *virus fixe*.

Material from the second human case was inoculated intracerebrally into a monkey and several rabbits. The rabbits all died from sepsis due to contaminating organisms in the inoculum, and further rabbits injected subcutaneously with brain emulsion or intracerebrally with a Berkefeld N filtrate remained well over a period of three months. The monkey survived with a localised cerebral abscess, and on the thirty-eighth day developed typical rabies; from its brain the disease was transmitted without difficulty to four generations of rabbits.

In all the experimental animals lesions characteristic of rabies existed in the central nervous system. Only some of the rabbits showed well-developed Negri bodies; in the monkeys, without exception, typical Negri bodies with "innerkörperchen" were present in the cornu ammonis, and often in other parts of the brain and cord.*

Cross-immunity tests between the Trinidad virus and the *virus fixe* (Paris strain) are not yet completed. As far as they go they reveal a partial cross-immunity between the two viruses, inasmuch as immunisation with the *virus fixe* protects against the intracerebral inoculation of Trinidad virus while the reverse does not obtain. The sera of animals immunised with *virus fixe* neutralises to an equal degree the two viruses. The final results of these tests will be published later; at the moment there seems no reason to doubt the close relationship of the two viruses, though the Trinidad virus appears to be poor antigenically and unable to protect against the highly virulent *virus fixe*.

The Disease of Cattle.

Since July, 1925, a disease diagnosed as botulism has occurred in cattle and the equidæ. In that year among various herds, totalling approximately 450 head, in and around the Queen's Park, Savannah (Port of Spain), there were 46 deaths. Outbreaks of the disease have since appeared throughout the island; cases have been less numerous around Siparia than in districts free from the human malady. Local veterinary surgeons, most of whom were thoroughly acquainted with the condition as seen in the United States and Canada, agreed that the disease was botulism, as did Dr. Robert Graham, of Urbana, Illinois, and Dr. G. E. Jacobi, of Minneapolis. Further, in two instances, one of us (J. L. P.) isolated the *Bacillus botulinus* from the liver and spleen by means of Bengston's cooked meat medium (1924), and Dubovsky and Meyer's medium (1922); the organism was also found in samples of soil and water from "infected" pastures. There seemed, therefore, no reason to doubt the diagnosis made.

The main symptoms consisted in constipation, grinding of the teeth, salivation, tremor and involuntary movements, muscular incoördination, and finally prostration, respiratory failure, and death; the disease evolved in the absence of any rise of temperature.

The owners of cattle among the labouring classes are mostly East Indians, who tend their animals with the same affectionate care as their compatriots in India, and are thus brought into close contact with them. Despite this fact only three of the 17 cases of the human disease occurred in East Indians, and in no single instance has even a remote connexion been established between a human case and infected cattle or their secretions. Epidemiologically, therefore, there seemed to be no connexion between the human and the bovine disease.

Nevertheless, from the brain of a cow suffering from so-called botulism we have obtained a virus similar to that from the human cases, while in the cornu ammonis of a second cow typical Negri bodies were detected. It appears, consequently, either that botulism and rabies exist side by side and are clinically indistinguishable, or, more likely, that the cattle disease is rabies, and the finding of the *B. botulinus* a chance occurrence unconnected with the real cause of death. Further investigation of this problem is proceeding, as are cross-immunity tests with the cattle virus and the *virus fixe*.

Discussion.

Consideration of the facts adduced leaves little doubt that the virus responsible for both the human and the cattle disease is that of rabies. That this conclusion could hardly have been foreseen in the early stages of the investigation was due to the unusual form taken by the disease in the human cases and the invariable, complete absence of any history of bites. Before proceeding to a discussion of these difficulties it would, perhaps, be well to summarise briefly the essential facts in our knowledge of rabies.

The symptoms of classical rabies are too well known to require mention, and it is to the histological features that we may first direct attention.

HISTOLOGICAL FINDINGS IN RABIES.

Since the description of Negri bodies (Negri, 1903) more and more trust for the histological diagnosis has been placed in the demonstration of these structures; occurring, as they do, in over 90 per cent. of the cases in man and animals (Negri Luzzani, 1913; Dwijkoff and Bogoslowskij, 1929), they are undoubtedly one of the most constant findings in the central nervous system.

Neuronal and inflammatory lesions, showing no regional affection corresponding to the site of the bite, are variable in degree and distribution; Dawydowski and Dwijkoff (1928) base their diagnosis largely on the absence of changes typically associated with other diseases. Schükri and Spatz (1925) and Lowenberg (1928) state that the intensity of the pathological processes is related to the length of the incubation period, but many other authors have failed to detect any such relation. Meningeal infiltration with lymphocytes and plasma-cells or occasionally with polymorphs (Lowenberg) is usually not marked, and this applies also to perivascular cuffing with the same types of cell. Certain modern authors (Klarfeld, 1922; Schükri and Spatz, 1925; Slotwer, 1926) find most marked inflammatory changes in the substantia nigra and midbrain, and some comment on the difficulties of diagnosis from encephalitis lethargica; others (Marchand, 1920; Krinitzky, 1926; Dawydowski and Dwijkoff; Bassoe and Grinker, 1930) place the most severe lesions in the floor of the fourth or the wall of the third ventricle, and even contrast their situation with that of the changes in encephalitis lethargica. Foci composed chiefly of proliferated microglial cells, the rabic nodules of Babes (1892) considered by him to be specific for rabies, are met with chiefly around the damaged motor nerve-cells of the brain-stem and cord. Lesions in the nerve-cells, consisting in chromatolysis, swelling, vacuolation or other degenerative changes, followed sometimes by neuronophagia, may be confined to the anterior horns of the spinal cord and the bulbar nuclei (Marchand; Lesieur, Lhermitte, and Jacquet, 1910), or may also occur in the cerebral cortex, basal ganglia or Purkinje cell layer of the cerebellum (Klarfeld, Lowenberg, Krinitzky, Dawydowski and Dwijkoff); it is, however, an interesting and important fact that the cells of the cornu ammonis containing the most numerous Negri bodies are usually comparatively intact. Cajal and Garcia (1904), Marinesco (1910), and others emphasise hypertrophy of the neurofibrils as a constant cellular abnormality in rabies; other observers (Marchand; Lesieur, Lhermitte, and Jacquet) have noted lysis of these structures. Goodpasture (1925) has described peculiar changes in the neurofibrils and mitochondria leading to the formation of Negri bodies, and Tupa (1929) swelling and disappearance of the mitochondria and of the Golgi apparatus.

The cerebro-spinal and sympathetic ganglia are frequently the seat of lymphocytic infiltration with marked destruction of nerve-cells, which are replaced by masses of small cells forming the nodules of van Gehucten and Nelis (1900); Dawydowski and Dwijkoff find the Gasserian ganglion most commonly affected. Chachina (1926) describes alterations in the sympathetic ganglia in each of ten cases. Nicolau, Nicolau and Galloway (1929) find scanty infiltrative lesions in the peripheral nerves.

It must, however, be recognised that none of these changes is necessarily an accompaniment of rabic infection; not only are many of them absent in some human cases, but in *virus fixe* infection it has long been recognised (Babes, 1912, &c.) that with increasing affinity of the virus for the nervous system of the rabbit, lesions tend to become less and less noticeable. Examination of several cases bitten by the same animal led Dawydowski and Dwijkoff to the conclusion that individual capacity for reaction varies greatly. The species of animal infected is also responsible for variations in the histological picture; França (1925), from a comparative study of rabies in a number of different animals, concludes that the only constant lesion is hypertrophy of the neurofibrils.

---

* When these findings were reported to Dr. Pawan, I was informed by him that a report in similar terms had been received from Dr. Simon Flexner, of the Rockefeller Institute, to whom also specimens of the first case had been sent.—E. W. H.

PARALYTIC RABIES AS A CLINICAL ENTITY.

Turning now to less usual clinical manifestations of rabic infection, the question of paralytic rabies, which incidentally is normal in herbivora and rodents, immediately enters the field of inquiry. The occurrence of this clinical type in man has been recognised since the time of Gamaleia (1887), and though numerous cases have since been described but little can be added to his description. It is commonly held that such cases are more particularly apt to arise after extensive bites—e.g., by rabid wolves—where the infecting dose of virus is presumably very large, and after bites on the limbs rather than of the face. A study of the literature gives the impression that they occur more frequently when Pasteur treatment has failed to prevent the onset of rabies. This impression may, of course, be fallacious for two reasons: firstly, that even where prophylactic measures are abortive only the cases of atypical course are recorded; secondly, that the cases in which treatment is of no avail are most likely to be those receiving an overwhelming dose of virus. It is not irrelevant here to recall that the cases of paralytic rabies arising during or after antirabic treatment must be sharply differentiated from those of the so-called paralytic accidents, in which the lesions (Fielder, 1916; Stuart and Krikorian, 1928, 1930; Bassoe and Grinker, 1930), quite different from those of rabies, are identical with those in post-vaccinal encephalitis.

According to Gamaleia, the symptoms of paralytic rabies begin with fever, malaise, headache, and vomiting. Pain is felt usually in the bitten part, but may take the form of girdle-pain. Paresis beginning in the bitten limb is accompanied by fibrillary contractions, and rapidly increases to complete flaccid paralysis; if noted at all, sensory loss is of late development. Preceded by pains, the paralysis spreads to the other limbs, the trunk, rectum, and bladder; the face, tongue, and eyes are not spared. The respiratory centre is involved more or less late in the course of the illness, and to a greater or less degree; dyspnœic convulsions may occur, but death results from cardiac paralysis. The total duration of the malady is, on an average, seven and one-half days, compared with three days for the ordinary form of the disease. The symptoms prove that the whole of the grey matter of the cord is affected —i.e., there is a "total poliomyelitis."

Among others, van Gehucten (1908), Babes (1912), Higier (1912), Marie and Chatelin (1919), Lubinski (1921), Uribe (1924), Fedoroff (1925), Knutti (1929), Gutmann (1930), and van Wulfften Palthe (1930) have reported cases, while Remlinger (1906) accepts rabies as a cause of Landry paralysis.

These later cases have often been described under the term Landry paralysis, and have sometimes, during life, been diagnosed as poliomyelitis. Four have arisen in untreated patients; in the remainder antirabic treatment was in progress or had been completed. In the majority the bite was on the hand or leg, but in at least one (Marie and Chatelin) the boy was bitten (slightly) on the lip. As premonitory symptoms, many of the cases have shown depression or other psychical disturbance, together with pain in a leg or in the scar resulting from the bite; anxiety or depression have often been marked during the course of the illness. All evolved with ascending paralysis as the dominant clinical feature; sensory loss was definite only in Knutti's patient, and here, as will be seen later, the pathological changes were of a different order from those in the remainder. In Higier's case general hyperæsthesia was noted. In many, but not in all, retention or incontinence of urine and fæces was present. In roughly half, paralysis of the muscles of articulation and deglutition, with difficulty in swallowing, occurred during the terminal stages. Salivation was a feature of several cases. Hydrophobic spasms have been described by van Gehucten. From a perusal of his article it seems likely that here they were of psychical origin; the patient had expressed a fear of becoming rabid, and hydrophobia was elicited only by attempts to swallow water and not other liquids or saliva. In two other cases difficulty in swallowing, presumably spasmodic, appeared early in the illness. Ocular paralyses have been unusual, but have been recorded by van Gehucten and van Wulfften Palthe. In every instance death has followed within 4–12 days from respiratory or cardiac paralysis, or from a combined failure of the two vital centres, and has often been preceded by dyspnœic attacks. In most of the instances cited, the diagnosis has been confirmed by the finding of Negri bodies, by animal experiments or by both methods; in the remainder no reasonable doubt exists regarding the diagnosis.

Koch (1912) described a case of ascending paralysis accompanied by anæsthesia but without hydrophobia, and coming on during antirabic treatment. Partial recovery had occurred when two months later the patient succumbed to sepsis. Some of the animals inoculated with cord emulsion died of sepsis; the remainder died after long incubation periods of a condition corresponding to "consumptive rabies," without showing, bacteriologically or otherwise, a definite cause for death. Koch believed that the rabic virus was responsible for the paralysis.

Concerning the frequency of this form of rabies, Höyges (quoted by Babes, 1912) saw 12 cases among a total of 86, Koch 2 among 8, and Dawydowski and Dwijkoff 20 among 94. No previous author has described a series of 17 consecutive cases all of the paralytic variety, and unattended by any examples of the classical disease.

HISTOLOGICAL FINDINGS IN PARALYTIC RABIES.

The lesions in these paralytic cases are often not described, while in others they appear to have been similar to those in typical rabies.

In van Gehucten's case the cord showed no vascular lesions and only some chromatolysis of the anterior horn cells, though severe changes were found in the spinal ganglia; he comments on the lack of correspondence between clinical symptoms and pathological alterations.

Higier reported the presence in the spinal cord, and to a less extent in the pons, of marked perivascular cuffing, with diffuse lymphocytosis affecting particularly the anterior horns and following to some extent the grouping of vessels and nerve-cells; chromatolysis was evident in the anterior horn cells and in the Purkinje cells of the cerebellum, and Babes nodules existed in the pons.

In Fedoroff's case the most intense lesions, congestion, perivascular and tissue infiltration, were situated in the spinal nerve-roots, while in the cord some perivascular cuffing was unaccompanied by abnormality in the nerve-cells; a double central canal with surrounding gliosis representing a developmental defect may have predisposed to the abortive result of treatment.

Marie and Chatelin describe the changes present in their patient as an acute infiltrative polio-encephalomyelitis. Perivascular and parenchymatous infiltration, with nerve-cell degeneration, existed alike in the spinal ganglia, grey matter of the cord, medulla and pons, cerebellar cortex, and parts of the cerebral cortex; these changes attained their maximum in the ganglia and cord. In the latter infiltration was largely nodular, with hypertrophy of neurofibrils, disappearance of the nuclei of the nerve-cells and considerable neuronophagia; anterior and posterior horns were equally involved. In the brain-stem infiltration was less marked and more diffuse. In the cerebellum the inflammation was localised to the Purkinje cell layer; in the cerebrum the cornu ammonis was particularly affected, though the nerve-cells were well preserved.

Gerlach (1925) does not record the clinical course of his case, though presumably it was of the type under discussion. He found a diffuse, in places hæmorrhagic myeloencephalitis, with complete softening of the lumbar cord. Lesions in the cord, situated chiefly in the grey matter, consisted in diffuse lymphocytic and leucocytic infiltration, massive perivascular and pericellular infiltration with advential elements and leucocytes, and all degrees of nerve-cell degeneration up to complete destruction. Inflammatory changes continued into the brain-stem and basal ganglia, where however they were much scantier.

As he claims, Knutti's observations are unique, since in contrast to the foregoing accounts he describes destructive lesions of both grey and white matter of the cord. In the lumbar region he found pial infiltration with lymphocytes and plasma-cells. In the white matter extensive diffuse destruction had left no fibres intact, and the tissues were uniformly infiltrated with lymphocytes and with mononuclear leucocytes containing phagocyted nuclear material and fat. (The illustrations suggest that the latter cells were microglial.) The vessels showed lymphocytic sheathing. Necrosis and infiltration with all stages of degeneration in the nerve-cells were seen in the grey matter; most of the large motor neurons had disappeared, and the remainder contained Negri bodies. In the posterior nerve-roots, numerous foci of destruction of axons and myelin sheaths gave rise to spaces containing granular material, lymphocytes, plasma-cells, and large mononuclears; the anterior roots showed far less severe alterations. Animal experiments were positive. In this case there was no history of a bite, and ten days prior to her illness the patient had been vaccinated against small-pox; she had had no reaction. The vaccine used was tested for rabies virus with negative results. The nature of the lesions in the nervous system, together with the presence of Negri bodies and the positive animal inoculation, seems to rule out completely the possibility of post-vaccinal encephalitis, which might otherwise have been suspected.

THE TRINIDAD DISEASE AND THE POSSIBLE VECTOR.

The cases described in the present paper are interesting for a variety of reasons. All were of the paralytic type, and in the absence of, or with failure to detect sensory changes, the earlier cases were accepted as examples of the Landry syndrome; it seems desirable that cases with this diagnosis—e.g., that of Viswanathan, 1929—in countries where rabies is common, and even in those apparently free from the malady, should be investigated experimentally.

It is very difficult to envisage a cause for the unusual clinical features. We shall shortly discuss whether, in spite of the absence of history, the patients had been bitten by rabid animals; however this may be, to escape notice the bites cannot have been deep or extensive, as they usually have been in paralytic rabies in man. Nor do the experimental results suggest that the Trinidad virus is either more or less virulent than the average street virus. Remlinger and Bailly (1930) failed to obtain evidence of the plurality of the rabic virus, which varies only in its activity and aggressivity, but the possibility of a modification of the virus in a manner analogous to that of the small-pox virus in alastrim, or in an opposite direction, must receive consideration. There is no indication in the literature that rabies takes an unusual form in races other than European, and the victims in Trinidad have belonged to two totally distinct racial stocks. Individual predisposition can hardly be a factor in each of 17 cases.

A somewhat similar modification of the symptomatology of rabies is witnessed in the "oulou fato" of dogs in West Africa; here fury, normally seen in canine rabies, is very rare, and the manifestations are almost wholly paralytic. It has, in fact, been questioned whether the disease is rabies and whether it is transmissible to man, though the work of Remlinger and Curasson (1924), Laigret (1926), Dabbadie (1930), Remlinger (1930), and others has established beyond doubt its identity. But in the exceptional cases of transmission to man, exceptional probably because the animals show little tendency to bite, there is no record of an abnormal clinical picture. Woodhead (1906) stated that, whereas in dogs generally the malady takes the paralytic form in 15–20 per cent. of cases, in Turkey nearly all cases assume this form.

The bearing of the findings of Kobayashi (1925) on the problem in hand depends on the interpretation placed upon his results. In the Japanese encephalitis epidemic of 1924, believed to be encephalitis lethargica, Kobayashi succeeded in isolating from a single case a virus capable of indefinite transmission in animals. He himself recognised its affinity with the *virus fixe*, and Cowdry (1927) demonstrated that it was in fact a true rabic virus. If the Japanese findings could be accepted unreservedly, they would indicate the ability of the rabic virus to give rise to a clinical condition differing widely from classical hydrophobia. Apart, however, from the fact that the virus was obtained from only one of a number of cases investigated, symptoms in the experimental animals did not appear until the third passage, leaving some uncertainty whether the virus originated from the human material or not.

It is unfortunate that the accident mentioned prevented a detailed histological study of the Trinidad material. In Case 2, lesions in the cord appear to be scanty, as frequently happens in this region in typical rabies. In Case 1 much more marked changes, probably as severe as those described by Marie and Chatelin and by Gerlach in their paralytic cases, are present. From the fact that many of the cords examined have shown, macroscopically, complete softening in the lumbar region, we may per that Case 1 is in this respect the mor of the group. It will be interesting, if further cases occur, to see whether any of these individuals with myelitic symptoms show the unusually severe lesions described by Knutti.

Concerning the transmission of the disease in Trinidad we have no definite information. The epidemiological evidence indicates that the human affection as a whole is not directly connected with the cattle disease. Cow's milk is consumed by the native population, but there is evidence available (Mugrage, 1930) against the possibility of inducing rabies by feeding with the milk of rabid animals, so that treatment of persons drinking the milk of infected cattle is not necessary. From analogy with rabies elsewhere, we should, however, be disposed to look for a common vector of the two outbreaks. The biting of cattle by a rabid animal, especially if small and less obtrusive than a mad dog, might easily pass unnoticed; can we assume that 17 human beings might be bitten without their knowledge? The following work of Haupt and Rehaag (1921) may conceivably furnish an answer.

Haupt and Rehaag described a severe enzoötic in Brazil from 1908 onwards. In one district, between 1913 and 1918, 30 per cent. of the total horses and 15 per cent. of the cattle died of rabies. No rabid dogs were known to exist, and wholesale destruction of dogs made no impression on the case-incidence. It was then noticed that a swiftly flowing *river impassable to dogs proved no barrier to the spread of* infection, and that the heaviest mortality occurred in the most thickly wooded districts. Vampire bats (*Phyllostoma superciliatum*, Burmeister†) were next noticed to fly by day—an exhibition of quite abnormal behaviour; cattle bitten by these bats afterwards developed rabies. Finally, experimental investigation of a bat caught biting a cow *confirmed the supposition that these creatures were the* vectors.

It may be that here we have the clue to the origin of the Trinidad epidemic, and investigation along this line is proceeding. Vampire bats occur in the island, which lies within a short distance of the mainland of South America, and are known to bite men and animals; in explanation of its illness, the owner of the cow from which rabic virus was isolated stated that "bats had sucked the life out of the animal." Moreover, a bat may bite a person during his sleep without his being aware of the occurrence, and the toe is a common site for the trauma; we might thus account alike for the absence of history of bite and for the frequency, as the initial symptom, of paræsthesiæ in the foot. In connexion with the cattle disease, it has many times been remarked that removal of the herd from pasture to stall results in cessation of the epidemic; this was previously attributed to its removal from an area infested with *B. botulinus*, but, since lanterns are always kept burning in the stalls to scare away bats, an alternative explanation is forthcoming. If the outbreak is finally traced to bats, is it possible that passage of the virus through that animal's tissues has in some way modified its pathogenic action for man, so that it now produces only cases of paralytic type? Should the present line of inquiry yield negative results, it seems that we must search for a new and hitherto unrecognised mode of transmission of the disease.

In conclusion, we must acknowledge our indebtedness to Sir Wilfred Beveridge for placing his notes freely at our disposal, and to Dr. W. M. Scott for a supply of *virus fixe*.

Summary.

An outbreak of human rabies, which in each of 17 cases *took the paralytic form*, is described; in no instance is a history of bite by a rabid animal forthcoming.

The simultaneous occurrence of rabies in cattle is reported.

Epidemiological evidence does not suggest a direct connexion between the human and the cattle disease.

The opinion that the vector in both cases may be the vampire bat is *tentatively expressed*.

ST. JOHN AMBULANCE BRIGADE.—Last year members of the brigade attended 451,370 cases of accident and sudden illness. In his annual report Sir Percival Wilkinson, acting chief commissioner of the brigade at home, states that at the end of last year there were 1794 divisions and a personnel of 55,121, while 362 cadet divisions had a membership of 7356. The net increase in strength during the year was 103 divisions, 2752 members, 203 cadet ambulance divisions, and 343 nursing divisions. The work has increased with especial rapidity in London, and in the past two years the strength of No. 1 (Prince of Wales's) District has consequently been augmented by 1171 members.

---

† Captain J. G. Dollman, of the Natural History Section of the British Museum, kindly informs us that the blood-sucking vampire bats belong to three genera—desmodus, containing the common South American vampire *D. rotundus* and the Central American *D. rufus*; diæmus, from South America; and diphylla, from Brazil. The blood-sucking bat of Trinidad is the *D. rufus*.

SHOULD HIGH BLOOD PRESSURE BE REDUCED ?

BY I. HARRIS, M.D. KÖNIGSBERG,
HONORARY PHYSICIAN, LIVERPOOL HEART HOSPITAL ;
AND
C. L. G. PRATT, M.D. LIVERP.,
MAURICE STERN RESEARCH FELLOW.

THE question whether high blood pressure ought or ought not to be reduced is of great practical importance. An attempt has been made here to decide it by an experimental method. The idea underlying the investigation is to reduce the pressure artificially and to determine the cardiac reserve power as well as the renal function under the altered conditions.

Twenty-two patients were put on a standard diet, which was rigidly enforced for three weeks. During the first week no drugs were given; during the second week pressure-reducing drugs were administered; in the third week again no medicine was given. Collosol sulphur (Crookes), 3 c.cm. daily, was injected intramuscularly in the majority of cases; the effect of this drug on pressure is both profound and lasting. Erythrol-tetranitrate was, however, employed in some cases. The following tests were applied each week: water-excretion test, water pituitrin excretion test, blood-urea, blood non-protein nitrogen, blood uric acid, alkali reserve, blood chlorides, chloride concentration test, blood phosphates, and ammonia coefficient.

* Expressed as mg. per cent. nitrogen.
Av. = Average.

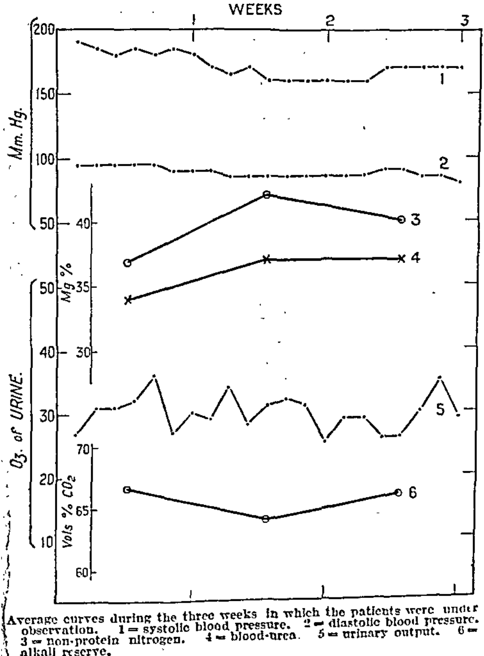
RESULTS OF TESTS.

Water excretion was normal in all the cases under review as long as no pressure-reducing drugs were employed. During the period in which patients were under the influence of pressure-reducing drugs the great majority of cases showed a marked reduction in the water-excretion power. In one instance, however, there was an increase in the water excretion in the second week when the patient was under the influence of the pressure-reducing drugs. The drug employed in this case was erythrol-tetranitrate, which, as already seen, does not exercise a lasting effect on pressure.

Perhaps as significant a fact as any is the marked reduction in urinary output during the period the patient was under the influence of pressure-reducing substances. The reduction is particularly marked in cases of polyuria. It is clear that such an elementary function as water excretion becomes depressed in cases where pressure-reducing drugs are employed.

Blood-urea was increased in all cases during the period of observation when the patient was under the influence either of collosol sulphur or of erythrol-tetranitrate, 40 mg. of urea per 100 c.cm. of blood being considered the limit of normal blood-urea values. In the first week all cases but two showed normal blood-urea content. Under treatment, there were actually eight cases which showed an abnormally high blood-urea of 40 mg. upwards. It is obvious that there is definite urea retention in cases of high blood pressure after the administration of pressure-reducing drugs.

Non-protein Nitrogen.—There was only one patient out of 22 who did not show an increase of non-protein nitrogen when under the influence of pressure-reducing drugs. This patient showed also an increase of alkali reserve when under the influence of



Average curves during the three weeks in which the patients were under observation. 1 = systolic blood pressure. 2 = diastolic blood pressure. 3 = non-protein nitrogen. 4 = blood-urea. 5 = urinary output. 6 = alkali reserve.

pressure-reducing drugs. Non-protein nitrogen retention is doubtless evidence of functional failure of heart or kidney; for the purpose of this paper it does not matter which.

Alkali Reserve.—This test represents the buffer value of blood plasma. If free acids stronger than carbon dioxide are produced in the body they replace it from combination with the buffer salts and so diminish the alkali reserve power. As is well known, under normal conditions the kidney excretes a large amount of acids in order to maintain the pH equilibrium. A failure on the part of the kidney to excrete the acids would thus lead to a diminished alkali reserve.

Alkali reserve was generally diminished as a result of the administration of pressure-reducing drugs. In the great majority of instances there was retention of uric acid, phosphates, and chlorides, and the chloride excretion test was depressed.

The figure shows the average variation in blood pressure, non-protein nitrogen, blood-urea, urinary output, and alkali reserve in the 22 cases over the three weeks' test period.

CARDIAC CONDITION AND PRESSURE-REDUCING DRUGS.

The cardiac power was tested the first week, when the systolic pressure remained normal, and the second week, when it was reduced. There are a number of reactions practised at the Heart Hospital[1] which give a definite indication of the cardiac condition. Foremost among these is the relation of stroke volume at rest to stroke volume at work. It was found in the normal heart that the stroke volume (cardiac output per beat) is greatly increased as the result of exercise. In the diseased heart, on the other hand, the increase is only moderate or is absent. The same standard test was used in all cases. Similarly the cardiac output per minute after work is larger in health than in disease. Another important test refers to the time in which the oxygen consumption becomes normal after the standard exercise. The shorter the period in which the oxygen consumption becomes normal the better the condition of the heart.

TABLE II.—*Cardiac Output and Stroke Volume under Conditions of Reduced and Unaltered Pressure.*

Case.	Before and after reduction of pressure.	During rest.		After standard exercise.		Requirement in c.cm. of oxygen.	Time after exercise in minutes when oxygen consumption becomes normal.
		A = Cardiac output per minute in litres. B = Stroke volume in c.cm.					
		A	B	A	B		
18	Before.	5·4	72	10·5	100	1916	12
	After.	5·5	62·5	8·96	74	2172	20
22	Before.	4·8	53	9·9	97	1752	12
	After.	4·5	48	7·5	64	2290	16
19	Before.	5·8	56	11·4	95	1132	11
	After.	4·7	50	8·7	78	1668	12
6	Before.	5·6	54	11·5	108	2016	8
	After.	4·6	50	8·8	97	2132	12

Yet another important reaction refers to "requirement." By this term is understood the cost of oxygen which a standard exercise entails. The worse the condition of the heart, the greater the consumption of oxygen. Table II. gives a clear indication of all these reactions in the first week, when the systolic pressure was not disturbed, and in the second week, when the pressure was reduced.

These tests prove conclusively that the heart suffers definitely as a result of treatment by pressure-reducing drugs. This result is not difficult to understand, as an adequate pressure in the aorta is of vital importance for the coronary circulation.

Various attempts have been made to seek the cause of hypertension in various substances circulating in the blood, but with little success. Might it not be an endeavour on the part of the organism to keep the blood chemistry within normal limits? This may be the reason why nothing really abnormal is found in the blood chemistry as long as the blood pressure remains high. It is only when the pressure is reduced artificially, and thus a condition of artificial heart failure brought about, that there is abnormal retention of substances in the blood in these cases.

CONCLUSIONS.

(1) The water-excretion function is definitely depressed as a result of administration of pressure-reducing drugs. (2) There is retention of urea, non-protein nitrogen, phosphates, and chlorides in the blood as a result of pressure-reducing drugs, while the alkali reserve is generally lowered. (3) The cardiac function is definitely impaired as the result of the treatment. (4) The conclusion is that it is not desirable to administer pressure-reducing drugs as routine treatment in cases of hypertension.

The cardiac output determination was done by one of us (I. H.) and Dr. I. J. Lipkin.

IODINE POWDER IN THE TREATMENT OF CHRONIC OTORRHŒA.

BY N. ASHERSON, M.B. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL; SURGEON FOR DISEASES OF THE EAR, NOSE, AND THROAT TO THE QUEEN'S HOSPITAL FOR CHILDREN.

IODINE powder, consisting of a 1 per cent. intimate suspension of iodine crystals in boric acid, is a valuable adjunct to the treatment of chronic uncomplicated suppurative otitis media associated with a marginal perforation and granulations. This type of case invariably proves resistant to ordinary conservative treatment and an operation is the usual advice profferred. The powder is one highly spoken of by American otologists.[1] It is termed iodine powder because the iodine is the active principle and the boric powder chiefly the vehicle for application. It is made by grinding up iodine crystals with boric acid in a mortar.

In deciding what line to adopt in the treatment of quiescent chronic uncomplicated otorrhœa, it is necessary to divide the cases into certain clinical groups: (1) Those with a central perforation of adequate size in the tympanic membrane. These cases, with one or two exceptions, can be cured instantly and dramatically by a single ionisation with zinc sulphate. (2) Cases with a marginal perforation—a large number of these cases can be cured by treatment with iodine powder. (3) Cases of cholesteatoma, for which operation is indicated. (4) Cases with an intact tympanic membrane but with fistula into the mastoid process, on the posterior or superior wall of the osseous meatus. A mastoid operation will be necessary for this class.

---

[1] Lederman, M. D.: Laryngoscope, 1930, xl., 397.

TREATMENT OF THE MARGINAL PERFORATION.

The tympanic membrane has a perforation, which extends to and involves the annulus tympanicus and is associated with granulations, which are sessile, pedunculated, or may be simulated by pouting mucous membrane. The posterior superior quadrant is the common site. After thorough cleansing of the meatus, it is often possible to aspirate secretions from the attic. The meatus is thoroughly cleansed by syringing and mopping. All adherent sloughs are removed and the pent-up secretion aspirated with the Siegle speculum. Any large granulation is removed after the application of cocaine and adrenalin. The meatus is filled with absolute alcohol for ten minutes and then thoroughly dried by mopping. A 1 per cent. iodine in boric acid powder is insufflated into the meatus, filling it completely. The patient is instructed not to touch the ear, except to mop out any discharge with a cotton-wool applicator. He is seen at intervals of four days at first, but later at intervals of seven days, when the ear is again insufflated with the iodine powder without any further preliminary treatment with alcohol. This is repeated until the ear heals—usually within two months.

The treatment is painless and the iodine does not produce any effect on the skin of the meatus. If the powder is still to be seen at the weekly visit, the discharge has diminished to a minimum or has ceased completely. To obtain a view of the tympanic membrane it will then be necessary to remove the powder by syringing. If the lesion is present (in the early stages it is often present but quiescent, presenting a pale picture, compared with its congested red appearance at the commencement of treatment) the powder is again insufflated. If there is any doubt whether there is any discharge or not, the powder test should be applied. This consists of insufflating boric powder and seeing the ear next week. The presence of the powder, undisturbed and snow-white, is proof positive of the absence of any discharge in the interim.

Effects of the Iodine Powder.—The profuse discharge rapidly abates, often after the first application, the ear remaining free from any overt discharge. Thus, as far as the patient is concerned, a "cure" of the otorrhœa has been wrought. He is freed from a troublesome discharge and is rid of the ritual of a daily aural toilet. Though at this stage otoscopy would reveal the absence of any powder and the focus is still active, the patient is delighted with the results. Parents are pleased that no active treatment is required from them at home. The fœtor of the discharge will disappear, and within a week or two the otorrhœa becomes inodorous, gradually muco-purulent, mucoid, and, in successful cases, finally ceases completely. The sessile granulations shrink up, as does the œdematous prolapsed mucous membrane pouting down from the attic region and from the periphery of the perforation. A rapid epithelisation occurs, and within a few weeks will be complete.

I have repeatedly observed a cure of the otorrhœa in cases with a marginal perforation with granulations. Many of these cases had failed to react to all other forms of active treatment and it appeared that *only* operation was left, yet the iodine powder cleared up the condition. It is interesting that these cases heal by migration inwards of the periphery of the perforation, so that the latter assumes a central position, where it may remain patent or may completely close over.

I have also found the powder cure cases where there has been a central perforation, but not with the dramatic effect of zinc ionisation. Cases of central perforation with granulations on the periphery of the perforation are cured by the powder.

If there is any active discharge the powder never cakes or obstructs. It acts as a sponge, absorbing secretions. It only remains in situ if the discharge has ceased.

REPRESENTATIVE CASE REPORTS.

CASE 1.—A boy, aged 7, had had right and left ear discharge for two years, with occasional bleeding from the right ear but no pain. When seen on Nov. 24th, 1930, he had septic tonsils and adenoids. The right meatus was full of offensive pus: when this was removed a marginal perforation, situated in the upper posterior quadrant of the drum, was seen. Excessive granulations surrounded and occluded the perforation, which involved the annulus tympanicus. Secretions could be aspirated with the Siegle speculum.

The ear was cleaned and dried. Absolute alcohol was applied for ten minutes; the excess was mopped away and the meatus filled with 1 per cent. iodine in boric acid powder. On Dec. 1st no discharge was complained of, and the meatus was moist. It was filled again with iodine powder. On Dec. 8th there was no discharge, but there was no trace of the powder in the meatus. Silver nitrate was applied to the granulations, and iodine powder again applied. On Dec. 15th the ear was dry and iodine powder was reapplied. On Jan. 12th, 1931, the ear was dry, and on Jan. 26th the perforation was healed, and the child heard normally.

He had also had pus in the left meatus, the condition being the same as in the right ear, with attic granulations. The treatment was identical with that of the right ear, and within the same period the discharge had dried up completely and the perforation had healed.

No treatment is carried out in the interval between the attendances, but the frequency of insufflations must depend on the rapidity with which the discharge appears.

CASE 2.—A girl, aged 9, had had purulent, offensive discharge from the right ear, but no pain, for 12 months. She had had her tonsils and adenoids removed six months previously. When seen on Nov. 4th, 1930, she had a marginal perforation occupying the postero-superior quadrant of the tympanic membrane and annulus, surrounded by exuberant granulations, from which, after the ear had been thoroughly cleaned, offensive secretions, indistinguishable from cholesteatomatous debris, could be aspirated with the use of the Siegle speculum. Absolute alcohol was applied for ten minutes; the meatus was dried and filled with iodine powder. On Nov. 11th there was marked improvement; the pus was not so profuse in amount and not offensive. The meatus was again filled with iodine powder. On Nov. 18th there was no discharge, and the meatus was moist. Iodine powder was reapplied then, and again on Dec. 2nd and 9th. On Jan. 27th, 1931, the ear was dry, a dry perforation remaining.

CASE 3.—A girl, aged 11, had had purulent discharge from both ears continuously for seven years. There was no pain. She had been attending the out-patient department of a teaching hospital for months, but had never had tonsils or adenoids removed. When seen on May 9th, 1930, both ears had the meatus full of offensive pus. This was cleaned. Adherent offensive slough occupied the depth of the meatus, deep to which the entire meatus was occupied by a perforation which extended to the annulus tympanicus in all visible directions. Granulations pouted from the margins, and pus could be aspirated from the attic. For the three subsequent months she was treated with repeated zinc ionisations with little effect, the meatus being found to have a purulent slough in its depth each week. It was decided to advise operation. When the iodine powder treatment came under my notice this case was one of the earliest put on it. In the meanwhile the tonsils and adenoids were removed. On Sept. 12th the condition of both ears was the same as in May. Alcohol was applied for ten minutes, followed, after drying, by the iodine powder. This was repeated each week to both ears for six weeks, at the end of which period both ears were completely free from discharge. The patient was seen again in December, 1930, when the ears were dry and there was a complete *restitutio ad integram* of both tympanic membranes. The mother commented on the fact that this was the first time for seven years that the ears had ceased from discharging. Six months later the ear were still dry.

CASE 4.—A woman, aged 28, had had discharge from the left ear for many years, necessitating a daily aural toilet to keep the ear clean and free from odour. There was no pain. A perforation was observed through Shrapnel's membrane, marked by the usual sentinel granulations and extending on to the roof of the osseous meatus. It was covered by a yellow adherent slough, and a bent probe detected bone. The granulations could be sucked out of the perforation. Alcohol was applied, followed by iodine powder, and the treatment was repeated on Sept. 27th. One week later the ear had not run in the interval, though there was no trace of any powder left in the meatus. The powder was insufflated at weekly intervals, and within a month the ear ceased to discharge, and the patient was very impressed. The ear dried up completely.

I have treated over 300 cases with very gratifying results. The vast majority of these cases were between the ages of 5 and 15. Unfortunately, it is not possible to foretell which cases will respond to the iodine powder treatment or which will prove a failure. Many cases respond, much to the observer's surprise; while others, in which a good result should ensue, fail. But the treatment is well worth a trial before recourse to the radical operation.

CLINICAL AND LABORATORY NOTES

CASE OF
ASBESTOS-LIKE BODIES
IN THE LUNGS OF A COAL-MINER WHO HAD NEVER WORKED IN ASBESTOS.

By Frank E. Tylecote, M.D., F.R.C.P. Lond., D.P.H.,

PROFESSOR OF SYSTEMATIC MEDICINE IN THE UNIVERSITY OF MANCHESTER; HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY;

AND

John Shaw Dunn, M.D. Glasg.,

PROCTER PROFESSOR OF PATHOLOGY AND MORBID ANATOMY IN THE UNIVERSITY; SENIOR HONORARY PATHOLOGIST, MANCHESTER ROYAL INFIRMARY.

In March of this year a man, aged 71 years, was seen in consultation with a doctor ten miles from Manchester, and was later admitted to the Manchester Royal Infirmary under the care of one of us (F. E. T.). The doctor who had attended him reported that he had had several attacks of hæmoptysis in the preceding month, but as several recent sputum tests had had negative results the case had not been accepted by the local tuberculosis authorities.

The man himself said he was a coal-miner, and had as a young man worked in Alabama in mines. On consulting books of reference it was found that no asbestos is found in Alabama, which is noted for coal and iron, "Alabama iron" being famous all the world over. In 1923 it is stated that 80 per cent. of the asbestos produced came from that part of Quebec which is south of the St. Lawrence. Alabama and Lancashire mines were the only mines he had ever worked in. These points later became of interest and importance owing to the curious findings at the post-mortem and in the histological examinations of portions of tissue removed thereat, and later examined by one of us (J. S. D.).

On examination on admission to the hospital the man was very thin, obviously much emaciated, and very weak. There was a history of typhoid fever in December, 1929, and of operation for a strangulated inguinal hernia in December, 1930, since which time his health had never fully recovered. On Feb. 19th, 1931, he had his first hæmoptysis, spitting up "about four pints" of blood, while a few hours later a second hæmoptysis occurred. A cough had been constant since then, whilst the sputum remained blood-tinged and night sweats occurred. A week before admission a rigor occurred, and delirium followed, and persisted up to the time of admission. Examination of the chest showed nothing abnormal on the left side beyond the presence of a few râles and rhonchi over the lower part of the left lung behind. On the right was massive dulness, more marked below. Well below the apex at the back and to the outer side were signs of cavitation. The area of dulness surrounding the area of cavitation gave no evidence of softening to auscultation, but there was rather an absence of breath sounds. Low down in the right axilla friction was heard. A tentative diagnosis of pulmonary tuberculosis was made, with possible new-growth supervening. In the next 48 hours a positive sputum test was obtained. A blood Wassermann taken about this time was negative. The Widal reaction was positive to *Bacillus typhosus* 1 in 160.

Radiographic examination of the chest reported: "As the patient was unable to sit up satisfactory examination was impossible. The film taken shows displacement of the heart and mediastinum towards the right side. There is a large irregular opacity in the right lower chest, with mottling in the upper and middle lobes. There is some mottling also visible in the left middle and lower lobes. The appearances are not typical of tuberculosis, ? neoplasm."

The urine contained a trace of albumin. The pulse-rate at first was 90–100, but later rose to 116–120. The range of temperature was morning, 98°; evening, 99°–100°. He gradually got weaker, and died on April 14th. The autopsy was held on the 15th.

A synopsis of the post-mortem findings follows, with a description of the histology and some notes on these findings by one of us (J. S. D.).

REPORT OF AUTOPSY.

Lymph glands: Thoracic and abdominal glands along spinal column are heavily anthracosed.

Pericardium: About 100 c.cm. excess fluid.

Heart (400 g.): Enlarged; myocardium, hypertrophy, more marked right side; tricus. V, three fingers; mitral V, two fingers; aorta, early atheroma.

Right and left pleuræ: Each 500 c.cm., straw-coloured fluid. Right lung (900 g.): Whole of lower and lower half of upper lobe are firm, almost black with white mottling, and at apex of lower lobe a cavity containing

FIG. 1.

Asbestos-like bodies in the lungs, showing forms, with rounded ends. In Fig. 3 the central core can be clearly distinguished. (× 500.)

a ruffled wall and evidence of tubercle. Left lung (1300 g.): Lungs showed some degree of softness, as though some neoplastic invasion were present. Both lungs heavily anthracosed. Left consolidated only in its lower lobe. *No abnormalities evident in air passages.* General appearances suggest a chronic fibroid tubercle, possibly associated with a neoplasm.

Stomach: Nil. Small intestine: Some small tuberculous ulcers in lower ileum. Large intestine: Tuberculous ulceration of cæcum.

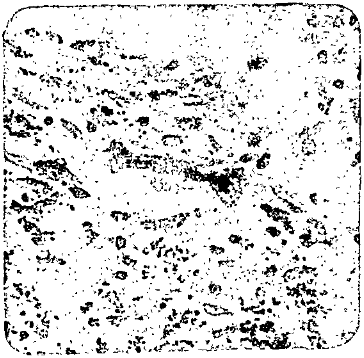
Liver (1600 g.): Moderate passive congestion. Pancreas: Nil. Spleen (310 g.): Enlarged and moderately firm. Hyperplasia and congestion. Thyroid: Nil. Adrenals: Nil. Right kidney (160 g.): Congested. Left kidney (160 g.): Congested. Urinary bladder: diverticula present. Genital glands: Middle lobe of prostate quite appreciably enlarged.

Anatomical diagnosis: Chronic fibroid tuberculosis of lungs. Pulmonary asbestosis.

HISTOLOGICAL EXAMINATION.

The extensive consolidation of the lower lobes of both lungs was found to be due to caseating tuberculosis with a very diffuse distribution; it appeared to represent a rapid lymphatic spread, and in large areas it completely obscured the lung-structure. Tubercle bacilli were present in moderate numbers.

FIG. 2.



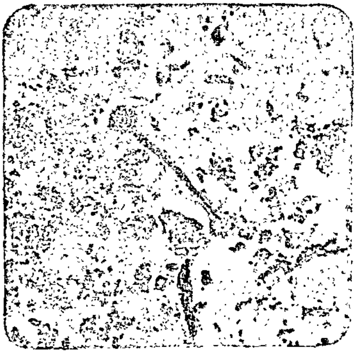
There was fairly marked anthracosis, the pigment in fine granules, being mostly aggregated in the peribronchial connective tissue.

The upper parts of the upper lobes were almost free from tuberculosis, and so it was possible to recognise a moderate patchy overgrowth of fibrous tissue in these areas. This was mature in type, but not very dense, and did not form laminated nodules. Here and there in the fibrous tissue were scattered some minute brownish bodies singly or in groups of *five to ten* (Figs. 1 and 2). They were mostly slender *rods with bulging ends*, and they measured from 30 to 70 microns in length by 2 to 5 microns in thickness. On high-power examination, it could be seen that most of these bodies had a black opaque *central core*, while the brown material formed an outer lamina and was semi-transparent (Fig. 3). There was no appearance of the regular segmentation *which commonly occurs* in asbestos bodies. On treatment with potassium ferrocyanide and hydrochloric acid, the brown material took on an intense *blue colour*, evidencing an abundant content of free iron. The bodies were subsequently recognised in all parts of the lungs, though nowhere numerous.

COMMENT.

The main point of interest in the case is the occurrence in the lungs of bodies which somewhat resemble those that have been described in the lungs of asbestos workers. They simulate these in size and general shape, especially in the rounded swellings at the ends; in colour; and in their abundant content of free iron. They differ from the familiar asbestos bodies in being usually coarser and less regular, in possessing a black core of opaque material, and in the absence of any appearance of segmentation. *It is presumed that they are minute fragments of* some other iron-containing mineral, which have been inhaled into the lungs and undergone some chemical change under the influence of the tissue fluids resulting in the formation of a peripheral lamina from the iron-containing part. They do not appear to have caused a very serious fibrous reaction in the lungs in this case.

FIG. 3.



GALLOP RHYTHM:

ITS CLINICAL SIGNIFICANCE IN CERTAIN CASES.

BY C. BLAXLAND LEVICK, M.B. SYDNEY,
M.R.C.P. LOND.,

ASSISTANT PHYSICIAN AND PHYSICIAN-IN-CHARGE OF CARDIOGRAPHIC DEPARTMENT, ST. GEORGE'S HOSPITAL; PHYSICIAN TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN.

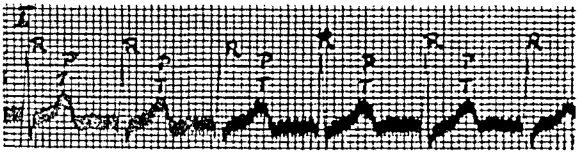
GALLOP rhythm has long been known to be a serious cardiac sign. The name is best reserved for the true gallop rhythm where the first heart sound is reduplicated (⏑⏑—); for, in agreement with Gee's teaching, a doubling of the second sound (—⏑⏑) is properly termed canter rhythm. It is important to differentiate between the two, for canter rhythm is heard in many conditions none of which is as serious as those which yield gallop rhythm. These two rhythms are easily confused, for even a slight degree of tachycardia may appear to accentuate the middle component of the three (⏑—⏑); and during the varying phases of respiration this accentuation will seem to move sometimes to the third component (⏑⏑—), sometimes to the first (—⏑⏑).

It is here desired to draw attention to a special variety of gallop rhythm, and to emphasise the importance of its recognition. For according to the age at which it appears it may be the only sign which either allows for the provision of adequate treatment or leads to a correct diagnosis and a more clear prognosis. This special variety is a reduplication of the first sound, clearly heard, over a small area close to the left border of the sternum at the second intercostal space or third cartilage. In many cases it will be heard at all the auscultatory areas; but if it is not audible at this localised spot, it is unlikely to be heard elsewhere. There are, of course, many cases where gallop rhythm is heard at the mitral area, yet not at the base; these belong to a different category.

ACUTE RHEUMATISM.

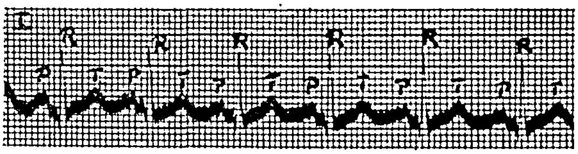
The significance in acute rheumatism varies with the age of the patient. In children and young persons it is almost always associated with delayed conduction from auricle to ventricle, the electrocardiogram showing a lengthened P–R interval. These two features, gallop rhythm and long P–R interval, are frequently the earliest evidence of rheumatic carditis. Tachycardia, about 120 per minute, is usually present, while the temperature may not be raised above 99° F. The discovery calls for immediate rest in bed; the earlier this is obtained, the more quickly does the P–R interval close. Administration of full doses of salicylates in addition appears to hasten the closure. If treatment is delayed or imperfectly carried out, the P–R interval may remain permanently longer than normal, and the gallop rhythm will then persist.

FIG. 1.



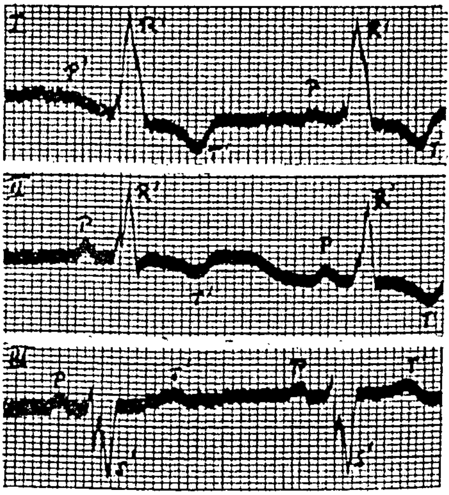
CASE 12.—Aged 15 years. Jan. 30th, 1929. Slight rheumatic pains. Gallop rhythm and tachycardia present; no other abnormal cardiac signs. Lead I. rate = 114. P. and T. fused. P–R = about 0·31 sec.

FIG. 2.



Same case.—Feb. 12th, 1929. No symptoms. No gallop rhythm. Rate = 95. P–R = 0·20 sec.

FIG. 3.



It is probable that the lengthened P–R interval is due to an infiltration of the auriculo-ventricular junction rather than to vagal effect, for atropine produces no alteration except in occasional cases. However, the effect of atropine on the P–R interval is a complex one, and as yet imperfectly understood. Sound-photographs seem to show that the earlier of the two short components is produced as a result of auricular contraction occurring outside its usual timing in the cardiac cycle.

Eighteen cases of this nature have recently been observed in patients under the age of 25 years. In each case a lengthened P–R interval was confidently predicted prior to electrocardiogram. Confirmation was clearly obtained in 17 cases; the eighteenth proved within normal limits. With early treatment, serial electrocardiograms on successive days revealed a rapid closure of the P–R interval; pari passu the gallop rhythm became less clear. Consequently, for purposes of confirmation it is necessary to take an electrocardiogram on the same day on which the gallop rhythm is clearly heard. Figs. 1 and 2 are electrocardiograms from a typical case.

CASE 1.—Girl, aged 15, seen in out-patient clinic at St. George's Hospital, on Jan. 30th, 1929, complaining of mild rheumatic pains in legs and arms; headaches; easily fatigued. No breathlessness or cyanosis. No history of scarlet fever or definite rheumatic fever. On examination, tachycardia, 116, persisting with rest and not due to nervousness. Temperature normal. Heart normal in size, regular rhythm; sounds normal except for reduplication of the first sound at the second left interspace near the sternum; no murmurs. Clinical diagnosis: First degree A–V block, probably rheumatic. Confirmed by electrocardiogram (Fig. 1) on same day. Admitted to hospital for rest in bed, no special treatment. Heart-rate gradually slowed, gallop rhythm became less clear. On day after admission, atropine sulphate gr. 1/25, subcutaneously, produced no effect on the P–R interval. Feb. 12th: Clinically normal, no gallop rhythm. Electrocardiogram normal (Fig. 2). November, 1930: Signs of early mitral stenosis. Electrocardiogram: P–R normal.

Effective treatment was denied to another girl in the first instance, owing to the true nature of her trouble being unrecognised. Now after several years' observation, gallop rhythm is still in evidence and the P–R interval remains abnormally long.

CASE 2.—Girl, aged 10, came to out-patient clinic at Victoria Hospital on May 6th, 1927, complaining of fainting attacks with loss of consciousness for 3–5 seconds. Scarlet fever at age of 7. No rheumatic history. On examination pulse 120, persistent, regular. Temperature normal. Heart normal in size. Apical first sound loud and slapping. First sound reduplicated at pulmonary area. Electrocardiogram confirmed clinical diagnosis of first degree rheumatic A–V block. P–R = 0·23 second for rate = 125 per minute. The parents refused admission to the Victoria Hospital and sought advice at another hospital, where apparently the nature of her trouble was not recognised, and no rest was ordered.

April, 1928: Returned to Victoria Hospital, still suffering from fainting attacks. Gallop rhythm still present. Electrocardiogram: P–R = 0·24 second for rate = 110 per minute.

No subsequent treatment, however, has been effective, and the clinical state and the electrocardiogram remain practically unchanged at the present time.

BUNDLE-BRANCH BLOCK.

In adults of middle age and older this form of gallop rhythm usually indicates a block in one branch of the bundle of His. It is more clearly heard when the right branch (old nomenclature) is affected. Fig. 3 is the electrocardiogram from a case of this nature, following a correct clinical diagnosis based on gallop rhythm heard clearly at the second left interspace, and at no other place; there was here no other clinical feature to suggest the diagnosis. Sound-photographs seem to indicate that in these cases the two short components are due to a slight asynchronism in the closure of the mitral and tricuspid valves.

Of 25 recent cases of bundle-branch block (B.B. block) gallop rhythm was clearly heard in 20; in the remainder the first sound in the second left interspace was not distinctly doubled, but was prolonged. Of the 20 cases with gallop rhythm, 12 were at the time practically symptomless; routine examination revealed the doubled first sound, suggesting a diagnosis of B.B. block prior to its confirmation by electrocardiogram. In other cases electrocardiogram revealed B.B. block when no doubling of the first sound had been observed; re-examination then showed a distinct reduplication in several of them. A definite diagnosis of B.B. block does not indicate any special treatment, but it certainly defines the prognosis more clearly than would be otherwise possible.

It is not contended that gallop rhythm is heard in all cases of first degree A–V heart-block and of B.B. block, nor that all cases of gallop rhythm yield an abnormal electrocardiogram. Rather is it claimed that its recognition in many cases may be of the utmost importance to prognosis and treatment.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Dr. H. **Crichton-Miller** took the chair at a meeting of this section when Dr. W. A. **Caldwell** gave a survey of probable prognostic factors in the treatment of

General Paralysis.

Pyrexia induced by malaria remained, he said, the most satisfactory method of treatment of general paralysis. Its value was enhanced by a short course of tryparsamide before inoculation and by the administration of N.A.B. after the malarial infection had been terminated. In general it was true that the younger the patient the better the prognosis, but age was not of paramount importance, and improvement might occur in the elderly. Nevertheless 71 per cent. of patients who were discharged from mental hospitals in a satisfactory condition were under 40 years of age. In women who had borne children the prognosis as to discharge from hospital was better than in nulliparous women. The character of the mental symptoms present was an indication as to the probable response to treatment. The expansive grandiose patients, who in his experience were the commonest, did best, and the juvenile and depressed paretics worst. In the case of the simple dements the outlook was moderately good. Dr. Caldwell stressed the importance of early treatment after the onset of symptoms of general paralysis. Those subjected to treatment during the first five months of their illness yielded the best results. There appeared, however, to be no relationship between prognosis and the incubation period which intervened between the primary infection and the development of general paralysis. He had observed a number of cases in which the Wassermann reaction had been negative in the blood but positive in the cerebro-spinal fluid.

Dr. F. R. P. **Taylor** said he had experienced some difficulty in inoculating women with malaria. He inquired as to the advisability of infecting with malaria a paretic woman who was pregnant.

Dr. C. **Worster-Drought** had found the demented type of paretic to be commoner that the grandiose. He questioned the occurrence of a negative Wassermann reaction in the blood in general paralysis, and emphasised the importance of a paretic Lange curve in the cerebro-spinal fluid.

Sir **James Purves-Stewart** remarked that the prognosis depended largely upon the stage at which the physician recognised the disease.

Dr. **Caldwell**, in reply, said that if a patient proved resistant to infection with the benign tertian parasite it was often possible to inoculate him with the quartan variety. He had treated a pregnant woman with malaria without ill-effects.

Exophthalmos of Central Origin.

Dr. W. **Russell Brain** read a paper on exophthalmos associated with organic disease of the central nervous system. Exophthalmos might, he said, occur in conjunction with paralysis of ocular movement either of the supranuclear or of the nuclear type. The conjugate ocular palsies found were usually in the vertical plane. Internal ophthalmoplegia occurred less frequently. Either retraction or ptosis of the upper lids might be present. Hyperglycæmia and glycosuria were common in these cases, and the thyroid might or might not be enlarged. The pathological nature of the causative lesion was often obscure. Encephalitis lethargica was responsible for some cases, and in another group the blood pressure was raised. Those patients in whom exophthalmos was associated with ophthalmoplegia and thyroid enlargement were of great interest, though ætiologically obscure. Exophthalmic goitre and myasthenia gravis had been described as occurring in the same patient. He showed lantern slides of ten of the cases described, and concluded that it seemed impossible to draw a hard-and-fast line between exophthalmic goitre and certain cases of organic lesions of the mid-brain.

Sir J. **Purves-Stewart** inquired whether there was any evidence of disease of the pituitary gland or of the cavernous sinus in the cases reported.

Dr. **Douglas McAlpine** pointed out that enlargement of the thymus was common to both exophthalmic goitre and myasthenia gravis.

Dr. **Russell Brain**, in reply, said that pituitary disease had been excluded in his patients, and that the ocular palsies were not characteristic of cavernous sinus disease. He hoped that further investigation of these obscure cases might throw light upon both exophthalmic goitre and myasthenia gravis.

Psychic Pain and the Psychoses.

Dr. H. **Devine** considered that psychic stress was not an important factor in the causation of the psychoses. If in a given case it appeared to be so there was usually a history of pre-existing mental abnormality. After discussing the biological significance of pain, Dr. Devine said that it seemed to be part of the scheme of things that life should have to struggle in a hostile environment. The difficulties of life could not be diminished by improving external conditions, and if in fact external factors were an important cause of psychical illness little could be done to prevent it. Schizophrenic patients renounced the pain and struggle of life and passed into a state which, as Jung had pointed out, resembled normal dreaming. They showed a deterioration not of the most recent but of the most primitive instinctive and emotional tendencies. Dr. Devine concluded that a vigorous intellect was not nearly as important a part of the equipment for life as a stout heart.

Dr. Crichton-Miller said that the problem before civilisation was not so much to maintain *mens sana in corpore sano* as to render the individual capable of meeting intellectual and spiritual demands which conflicted with the more primitive biological values.

Dr. H Cohen (Liverpool) showed a film illustrating the technique of air replacement in the radiological diagnosis of cerebral lesions, and discussed the diagnostic value of ventriculography and encephalography.

Sir J. Purves-Stewart also showed an interesting series of slides illustrating the results of encephalography in intracranial tumour and other conditions.

SECTION OF OPHTHALMOLOGY.

Ocular Palsies.

At a meeting of this section, with Dr. E. E. Maddox in the chair, Dr. Gordon Holmes said that few questions in neurology and ophthalmology were more difficult than the adequate analysis of an ocular palsy. Palsies might be due to lesions involving upper or lower motor neurones. A lesion of the lower motor neurone affected the muscles as such. A lesion of the upper motor neurone affected conjugate movements. The fibres of the dorsal longitudinal fasciculus connected the third, fourth, and sixth nerve nuclei. It was doubtful whether there are intercalary cells in the dorsal longitudinal fasciculus. Dr. Holmes divided palsies into three groups: (1) Paralysis of the ocular muscle due to disease of motor nerves or nuclei; (2) palsies of conjugate movements; (3) supranuclear ocular palsy.

1. Paralysis of ocular muscles due to disease of motor nerves or nuclei. Nuclear lesions were local, from hæmorrhage, tumour, or most commonly inflammatory, as in encephalitis. Wernicke's superior hæmorrhagic polio-encephalitis, often due to alcoholism, was of particular interest. Ptosis was its most common early symptom. In contrast to this acute lesion was a chronic nuclear ophthalmoplegia causing ptosis in middle life, and progressing to involve other muscles. Brain stem palsies of the intramedullary portion of the nerves were apt to involve the pyramidal tract before decussation, thus causing hemiplegia on the opposite side to the eye lesion. The ocular palsies of disseminated sclerosis were stem palsies. The paralyses of tabes might be nuclear, but were more often root palsies. The latter responded better to treatment. Compression of vessels by arterio-sclerotic vessels at the base of the brain might also occur. Any of the three ocular motor nerves might be so compressed. Rest and iodides usually cured the condition.

2. Palsies of conjugate movements did not usually cause diplopia. Lesions producing limitation of conjugate movements to one side usually lay near the sixth nucleus on that side. Dr. Holmes thought that the centre for depression and elevation of the eyes probably lay in the mid-brain.

3. Supranuclear ocular palsy usually showed inability voluntarily to move the eyes in some direction. When voluntary movements were lost in such cases the eyes *might* still be able to follow a finger reflexly.

Mr. Gayer Morgan said he was particularly interested in a group of cases superficially resembling tabes, but with a negative Wassermann reaction. Mr. Foster Moore had described non-luetic Argyll Robertson pupils in 1924. In Mr. Morgan's cases the tendon-jerks remained permanently inactive; the internal ocular paralysis of accommodation and light reaction might recover. These cases were sometimes of sudden onset. Dr. W. J. Adie had pointed out that the true Argyll Robertson *pupil* contracted briskly on convergence. In these cases the reaction to accommodation was slow and sluggish and typical of a benign condition.

Dr. Holmes in reply said most ocular movements were reflex, not mainly voluntary. He had seen a case similar to that of Mr. Maddox in which a supranuclear palsy prevented a patient looking to one side without looking down first. He thought syphilitic cases best treated by mercury and bismuth. He emphasised the preliminary fixed staring of the eyes before an oculogyral crisis. The eyes might deviate in any direction. He placed the site of lesion as probably in the corpus striatum.

Eye Symptoms in Encephalitis Lethargica.

Mr. T. H. Whittington, reading a paper on the Eye Symptoms and Sequelæ of Encephalitis Lethargica in 174 children, said the ophthalmologist found much interest in these cases. In the acute stage there were two common types: (1) "Influenza" with diplopia; (2) ocular palsies in a severe febrile illness. These acute cases often lost their ocular palsies before passing into the chronic form of encephalitis. In the chronic stage only 6 per cent. of the 174 cases had ptosis. Concomitant external strabismus was found in 15 per cent. The reaction to accommodation was affected in 47 cases, and light reaction affected in 23. Oculogyric crises occurred in six cases. These last were associated with parkinsonism. The eyes might roll up and the mouth become fixed open during a crisis, and crises might come as long as eight years after the acute illness; they were associated with emotional disturbance. Mr. Whittington suggested that these crises and symptoms might be release phenomena. The upward rollings of the eyes recalled the rolling up of the eyes in sleep and during gastro-intestinal upsets in infancy. Mr. Whittington pointed out that when hyoscine and stramonium were used in treating these cases the pupils became dilated and accommodation was paralysed. The effects could be counteracted by judicious use of pilocarpine and glasses.

Mr. D. V. Giri described a case of oculogyral crisis, and Mr. N. Bishop Harman mentioned the occurrence of ocular palsies when spinal anæsthesia was first brought into use.

Mr. Whittington in reply to a question said that he found no case of paralytic squint in his series. The only complaints of diplopia were during attempts at reading.

Shahan's Thermophore.

Dr. W. H. Crisp, of Denver, Colorado, in a paper on Shahan's Thermophore in the Treatment of Corneal Ulcers and other Eye Conditions, said that this apparatus was an efficient method of applying graduated heat to the eye. The heat was generated in an electrical resistance and conducted to the eye by a nickel-plated brass applicator. Serpiginous ulcers of the cornea responded well to treatment by the thermophore. Perfect anæsthesia by cocaine (5 per cent.), supplemented often by subconjunctival injection, was essential. The eye must be kept immobile during the application. Applications were graduated both in time and temperature. The machine could be used to provide sufficient heat to remove epibulbar growths. It was useful for troublesome small marginal chalazia.

Mr. W. CLARK SOUTER showed a series of orbital cases by lantern slides. He emphasised the frequency of orbital inflammations secondary to ethmoidal disease. He also laid stress on the importance in diagnosis of assessing accurately the secondary deviation of the eye.

SECTION OF HYDROLOGY AND CLIMATOLOGY.

THE Chairman, Dr. FORTESCUE FOX, in opening the section, said that the first part of medical hydrology, which had to do with medicinal springs, had a traditional practice in England as old as our history. The second part, which related to simple water, had opened a new chapter by the establishment of bath clinics in the towns. The third part of hydrology had to do with the sea, the greatest of mineral waters, in which terrestrial life originated. In the medical uses of the sea the British Islands, with their 6000 miles of coast, were deeply concerned. Those who practised hydrology must understand the good and bad effects of climate in the development of chronic diseases, because the operation of baths was powerfully affected by weather and climate. He believed that a whole new science of medical hydrology and climatology was being built up and that many medical men would in time devote themselves to these branches of practice. It was fitting to inaugurate this section at Eastbourne, with its typical south-eastern climate and excellent nucleus of medical baths; a town which was occupied, as the Prince of Wales had reminded them, in the national industry of turning out healthy boys and girls.

In that day's discussion on the care of

Delicate Children at the Coast

they had, he said, the advantage of the presence of a European authority from the premier (non-tuberculous) marine hospital at Wyk-auf-Föhr, where thousands of children from the German cities were given preventive and curative treatment for the various forms of delicacy which were the precursors of disease.

Dr. CARL HÄBERLIN, after referring to the earlier advocates of sea treatment, Russell and Lettsom in England and Lichtenberg and Beneke in Germany, discussed the treatment of the chronic and relapsing respiratory catarrhs from which the greater number of children sent to the sea suffer. Most of his observations were made on children sent from Hamburg. The hypersensitiveness of these children to colds and infections, he said, gradually diminishes by the sea, and in time smaller adenoid growths decrease so far as no longer to hinder breathing. Many operations on tonsils and adenoids, especially in children under six, may thus be avoided. The good results obtained in asthma Häberlin ascribes to cessation of irritation of the respiratory mucosa by dust and of the skin by over-heating, and to improvement in respiration. The continuous sea breeze stimulates even the clothed skin, and improves its function. He showed graphic records of the reactions of children under treatment. For example, the reaction to cold was investigated by small applications of ice in a number of town children newly arrived. At first the latent stage was long and the reactive redness faint. After some weeks at the sea the latent time diminished and the reactive redness increased. Another test was made by means of rectal and skin temperatures before and after cold baths. The "bad reactions," a considerable fall of temperature with slow and incomplete rise, diminished at the sea in from 50 to 28 per cent. of cases. The reaction to intracutaneous injections of tuberculin began and subsided more rapidly after treatment.

The fundamental and most characteristic effect of sea cure is not, Dr. Häberlin said, its influence on particular parts, but on the whole body. The umstimmung (toning or tuning-up of the whole body) is not a method of treatment of sick organs through direct influence on the seat of disease, but an alteration or modification of the whole body. As evidence of the stimulus to metabolism following exposure to the sea climate, he stated that in 116 children examined in conjunction with F. Müller, the heat production amounted to 2700 calories per diem on a small island, as compared with 1445 calories in a large town. It is notable that the metabolic changes and associated increase in muscular strength occur particularly during rest in the sun and air bath. The prompt improvement in appetite which occurs in 95 per cent. of children is not merely psychological (effect of change), but is due to increased metabolism and heat production, from continual stimulation of the skin. The abdominal circulation improves, chronic constipation is relieved, and the motor, secretory, and absorptive powers of the intestinal tract are increased. The increased activity of the peripheral circulation at the sea is a cardinal fact, and Fox and others have pointed out the significance of defective circulation in the skin in rheumatic cases. Children with nervous irritability are over-excited by new impressions and stimuli at the seaside; rest and limitation of time on the beach are therefore at first essential. At the Wyk Hospital much attention is given to the condition and functions of the skin. The relaxed skin is rendered tonic and active by dry rubbing, washing with cold sea water, air- and sun-baths, or by warm sea-baths, followed by cold shower-baths or sea-baths. Such applications are very brief and guarded; prolonged over-frequent sea- and sun-baths and endless paddling are deprecated as amounting almost to brutalities. As four weeks are in many cases necessary for acclimatisation, the visit to the sea should be of at least three months' duration. For more serious cases of catarrh, asthma, debility, and imperfect development, the stay should be prolonged to 6 or 12 months, or even longer. Treatment of most of the respiratory catarrhs by the sea is more important in winter than in summer.

Dr. PERCY LEWIS (Folkestone) enumerated the characteristics of the seaside climates; abundance of light, pure warm moist atmosphere, equable temperature with small variations, the presence of sea-salt in the air, and a dense atmosphere with frequent small variations of pressure. All the special features of seaside places stimulated metabolism. The abuse of marine climates—too sudden change of habits, too long exposure to sun and air, too much food, and too much excitement—were well understood at seaside schools. Delicate children at first improved during the term and relapsed in the holidays, and only after about a year returned to school without loss of weight at home. The strong stimulation of sea-bathing should only be used after acclimatisation, say one month, then only for short periods, twice or thrice a week.

Sir HENRY GAUVAIN (Alton and Hayling Island) compared the effect of open-air treatment at an inland hospital and by the sea. Children who react to this powerful stimulus do well, but for those who are not robust enough to respond, there is considerable risk. Leonard Hill and Argyll Campbell had found that the basal metabolism of children during sea-bathing was sometimes increased tenfold—a demand which strong children could meet, but the weakly required gradual acclimatisation. The following régime was adopted with success at Hayling Island hospital: (1) The children started with paddling only, the rest of the body being exposed to sun and air; (2) the body was sprayed with sea-water; (3) the children were immersed in the sea. After immersion they were given a hot drink while standing in a trough of warm water with towels round their shoulders, and then rested round a brazier. Differentiating the types which did well by the sea, Sir Henry stated that the freckling type did not respond well at the seaside. In general, he considered that for healthy individuals the stimulus of a seaside holiday produced better results in August, when the stimulating effect of the spring was wearing off, than when taken earlier in the year.

Dr. W. S. C. Copeman (London) summarised the reports received from medical officers of health and seaside practitioners on the coast in the five climatic regions: south, south-west, north-west, east, and south-east. The questionaire dealt with: (1) Particular indications in summer and winter; (2) malnutrition; (3) catarrhal conditions, indigestion, adenoids; (4) rheumatic and cardiac cases; (5) nervous instability, asthma, children from the tropics; (6) physical methods of treatment, the regulation of bathing.

Dr. H. M. Raven (Broadstairs) presented a joint medical report from the Isle of Thanet. Children with anæmia, debility, post-nasal catarrh, and chronic empyema did well all the year round, but improvement was most marked in summer. (From December to March certain cases, such as cardiac weakness, poor circulation, and rheumatism, should be treated with caution.) The available medical records from preparatory schools showed high average weight and growth. "Common colds" were not common in local open-air institutions; bronchial catarrhs cleared quickly in summer, but might persist for some weeks with little or no sputum in winter. Tonsils and adenoids were not much reduced except in minor cases. Rheumatic fever was uncommon, and the reporters state that convalescent children appeared to do better in Thanet than at some inland places. In the absence of throat infection, and if cases of minor pyrexia were isolated, acute recurrence was rare. Sea-bathing was not allowed for rheumatic cases. Sun- and air-baths are much used in open-air schools and convalescent homes, and children improve very much faster when the weather permits of this treatment, also moderate sea-bathing, excepting children with poor circulation. It is estimated that the number of bathers at Margate is 1,000,000 annually, at Broadstairs and St. Peter's 50,000.

Dr. K. R. C. Hallowes (Torquay) referred to the unexplained fact that anæmic children whose homes were by the sea improved when sent inland, just as inland children improved when sent to the sea. It would be interesting to know how far inland the iodine content of the sea air prevailed.

A RESOLUTION.

On the motion of the Chairman, seconded by Dr. Percy Lewis, a resolution was passed recommending that "in view of the increasing use of the climatic advantages and bathing facilities of the British marine resorts and of their great therapeutic value, both for children and adults, in the prevention and cure of disease, a medical organisation be formed to promote the scientific development of these forms of treatment in the British Islands."

REVIEWS AND NOTICES OF BOOKS

Injuries and Sport.

A General Guide for the Practitioner. By C. B. Heald, M.D., M.R.C.P., Physician with charge of Electrotherapeutic Department, Royal Free Hospital. London: Humphrey Milford, Oxford University Press. 1931. Pp. 543. 25s.

The title of this book is unfair to its scope. Bodily injuries are not, in this country at least, primarily associated with sport, and it may be doubted whether the injuries sustained as a result of sports differ in any essential way from other injuries. The book is not designed only for those whose duties are especially connected with the playing-fields or race-tracks, but will be read with interest by all practitioners. The early chapters contain the chief material upon which the book's claim to originality is based—the analysis of the processes of repair and the advocacy of electrotherapy. Dr. Heald believes repair to be effected by primitive, that is, undifferentiated, cells exuding from the blood, which later acquire the power of becoming differentiated into adult cells, just as the primitive cells of the ovum become differentiated in the process of embryonic growth, under the influence especially of their environment. The author's enthusiasm for electrotherapy is evidently based on a considerable experience. He describes and illustrates the more orthodox methods of treatment by splinting and immobilisation, but lays great stress on the value of anodal galvanism in relieving pain and in diminishing swelling due to effusion and muscular spasm. The general practitioner, to whom the work is addressed, is not at present in a position to be a dispassionate judge of electrical methods, but he is generally eager to try out new measures which are said to be beneficial in cases of injury. The short chapter on massage (physiotherapeutics) reflects a more general verdict. Neither in this section nor in that on electrotherapeutics is there any reference to the possible exclusion of children from these methods of treatment.

The book appears to be a very complete, though necessarily condensed, account of injuries and their treatment. The second and more extended part deals with specific injuries of bony and soft tissues in different parts of the body, and is summarised in a long appendix, which can be used as an emergency reference-table in diagnosis and treatment. The book has 380 illustrations, and on the fly-leaves will be found a diagrammatic index for both bony and soft-tissue injuries.

The study of this work will undoubtedly enlarge both the general outlook and practical efficiency of the practitioner in regard to injuries which sometimes cause him more worry than any other group of cases; the possibility of unusual complications, easily overlooked during attention to other surgical detail, is not ignored by Dr. Heald. After the practitioner has dealt with an emergency he will do well to ascertain from this book, with the help of the curious but useful index, in what ways he may be able to protect his patient from future disability.

Diagnosis and Treatment of Venereal Diseases in General Practice.

Fourth edition. By L. W. HARRISON, D.S.O., F.R.C.P.E., Director of Venereal Diseases Department, St. Thomas's Hospital. London: Humphrey Milford, Oxford University Press. 1931. Pp. 567. 25*s.*

THERE is sufficient new information in this book to make it worth buying even by those who have the third edition. The section on treatment of syphilis has been almost wholly rewritten, and care has been taken to emphasise indications for and against special preparations and their dosages at different stages of the disease. Every possible complication of arsenobenzol therapy is dealt with and the Abelin test of the brothers Lloyd is described, as a guide to the prevention of dermatitis and jaundice during 914 administration. The latest theory of E. B. Craven, Jr. (Johns Hopkins Bulletin, 1931), is added on a special slip facing page 378, stating the type of diet considered most likely to prevent jaundice during treatment. Full details of treatment for each stage of syphilis are given, and Colonel Harrison emphasises especially the danger of under-treatment. The one section in which more detailed instruction might be acceptable to the practitioner is that on treatment of the pregnant woman. The section on gonorrhœa and its treatment is sound both from the surgical and the psychological points of view. All usual complications of the disease are described and appropriate treatment is recommended. Vaccine therapy is fully discussed; in Colonel Harrison's view the recently produced vaccine of L. Dimond has so far proved by far the most valuable on the market. Non-venereal lesions which are liable to be mistaken for venereal conditions are described and illustrated by excellent plates. Dr. F. G. Crookshank has contributed an account, extending over 50 pages, of the medico-legal aspects of venereal disease, and admirable appendices give, in brief, descriptions of the Wassermann tests and of the various flocculation tests in common use; Lange's gold test is also described. The illustrations are good, some of the colour prints being particularly helpful.

Colonel Harrison's book should be of value not only to the general practitioner but also to the physician who sees in his wards the later visceral and nervous manifestations of syphilis, and whose knowledge of modern medication and dosage sometimes lags behind his clinical and diagnostic ability.

Farmacologia de la Digital.

By A. GAMIR. Madrid: Editorial Paracelso. 1931. Pp. 308. 7 pesetas.

THIS book is intended to provide Spanish pharmacists and doctors with a comprehensive survey of the main facts concerning digitalis purpurea. The author begins with a historical account of the plant from its first description by botanists up to the most recent attempts to elucidate its chemistry, and goes on to describe the botanical characters of digitalis, the various methods of cultivation, collection, preservation, and preparation of the leaves, and the means of identifying the pure drug and of recognising adulterations. A chapter is devoted to a discussion of its many official, non-official, and patented preparations, and a clear account is given of the chemical composition of its active principles. Of special interest to the medical man are the chapters devoted to an analysis of the action and uses of the drug, the methods of assaying its active principles, and the dosage when given by various routes. The book ends with an account of the toxicology of digitalis, and gives a number of reactions by which its presence can be recognised. It is a well-compiled and useful monograph.

The Doctor's Second Thoughts.

By Sir JAMES CRICHTON-BROWNE. London: Ernest Benn, Ltd. 1931. Pp. 294. 7*s.* 6*d.*

Sir James Crichton-Browne's successful book, "What the Doctor Thought," has here a sequel equally readable. In his long and distinguished career as a physician and mental specialist, Sir James has met many notable people, had many curious experiences, and maintained a keen interest in the scientific and literary aspects of the passing show. This collection of his notes made at the end of his day's work is, as was its predecessor, chatty and informative.

Unorthodox Reminiscences.

By Sir GEORGE TURNER, K.B.E., C.B., F.R.C.S. London: John Murray. 1931. Pp. 344. 15*s.*

Sir George Turner's autobiographical record is not one which would be anticipated from the consulting surgeon of a teaching hospital, and of this the reader will be warned by the title. The author makes little reference to surgery, as an art or science, save where allusions are pertinent to the running commentary of a man of the world upon the happenings of a life which professionally was medical and socially cosmopolitan. A description of a public school in the seventies brings vividly to mind the changes which 60 years have brought about in education—bringing-up, that is, and not tuition particularly—at those essentially national institutions; and some of what Sir George has to say of Uppingham will surprise his audience. But in essentials these examples of autocratic rule remain the same, and it is probable that if Sir George (like Mr. Bultitude) returned to his old school he would to-day incur the same credit and the same penalties for his independence as befell him more than 50 years ago.

A life-long connexion with St. George's Hospital, as student, teacher, and staff-officer, yields good material for reminiscence. The institution is dealt with according to the desultory scheme of the book. Very little is said of hospital administration, or the routine of education in lecture-room or ward; but there are neat portraits, kind and caustic, of various members of the staff; considerable tribute is paid to old hospital servants, and some of the stories illustrate aptly byegone times.

A large number of persons, distinguished in general society or in scientific circles, pass through these discursive pages as friends, travelling companions, and acquaintances of the author, and one chapter contains a sketch of G. J. Romanes of particular interest. Chapters dealing with queer coincidences, odd legal cases, and theatrical celebrities, and other chapters entitled, disarmingly, "A mixed bag" and "Pot-pourri," will repay reading for their anecdotes.

Sir George's love of racing was acquired in his cradle and found its practical expression while he was still at Uppingham. He is the reverse of ashamed of his successes at the ring-side, and it is easy to see that for him the pageant of the race-course and the heterogeneous attendance were the real attractions.

During the war Sir George Turner served with the Navy, with the rank of rear-admiral, and his connexion with the Service leads him to comment on the absence of surgical specialism directed to the needs of the blue-jacket. He outlines a scheme for the appointment of junior specialists from the large general hospitals as Aides to the Naval Medical Service. He would pay these surgeons a small retaining fee, and they could be summoned for special operations from the big towns nearest to the naval hospital where their intervention was needed. Sir George points to the fact that healthy young sailors do not form a large clinical field for special surgery, and that specialists deserving the title are the product of practice in crowded centres.

The book contains reflections upon many circumstances and situations where opinions are divided. Sir George Turner makes no concealment of his views, and would be surprised to find them acceptable to all. Indeed, it is easy to see that he enjoys to face opposition, a quality that gives entertainment to his unorthodox memories.

Journal of Pathology and Bacteriology.

THE following appear in the issue for July, 1931 (vol. xxxiv., No. 4, pp. 401–596).—A simple, delicate, and rapid method of detecting the formation of acetylmeythylcarbinol by bacteria fermenting carbohydrate, by R. A. Q. O'Meara (Dublin). An improved technique for the Voges-Proskauer reaction, using a simple culture fluid with sodium fumarate and testing with creatine and caustic soda.—Auto-hæmagglutination, by W. Boxwell and J. W. Bigger (Dublin). A clear and convincing example of this rare condition, in which the patient's serum agglutinated her own or any other human red corpuscles at room temperature.—Acetaldehyde as a fixative for neuroglia, by J. Gough (Cardiff). Followed by silver impregnation.—Mitochondrial changes in experimental oxalate and manium nephritis, by J. Gough (Cardiff). Mitochondrial changes are perceptible after an hour or two, and do not necessarily indicate irreparable damage.—The classification of Monilias by serological methods, by K. Stone and L. P. Garrod (London). By complement-fixation and precipitation tests all cultures obtained from cases of thrush were identical, and the majority of those derived from various pathological lesions belonged to the same group.—Compression fracture of the fourth lumbar vertebra of a calf, by T. Hare (London).—The action of Congo red on streptococcal hæmolysin and on *B. welchii* hæmolysin, by J. Gordon (Leeds). Congo red neutralises these hæmolysins, and the action is reversible; it does not neutralise saponin or bile salts.—Malignant phæochromocytoma of the adrenals, by E. S. J. King (Melbourne). Bilateral solid tumours of the adrenal medulla with secondaries in liver, lungs, bowels, bones, &c.; the cells relatively well differentiated, and many giving the chrome reaction.—An epizoötic produced by a hæmolytic streptococcus in laboratory guinea-pigs with abscess formation, by W. W. Beattie (Montreal). Acute and chronic lesions caused by an organism indistinguishable from *S. pyogenes*.—Further observations on testicular extract and its effect upon tissue permeability, by D. McClean (London). The author has failed to identify or isolate the substance in extracts of testis, which has such a remarkable effect on the dispersion of particulate emulsions injected into the skin and on the taking of vaccinia virus.—The interactions of staphylococcus toxin anatoxin and antitoxin, by F. M. Burnet (Melbourne). A thorough and scholarly study of staphylococcus toxin, the modification produced by treatment with formalin, and the neutralising antitoxin, which seems likely to be of practical value.—Lesions of the adrenal glands of rabbits caused by infection with herpes virus, by W. Smith (London). Some strains of virus produced a generalised infection after inoculation into the skin.—A new series of graded collodion membranes suitable for general bacteriological use, especially in filtrable virus studies, by W. J. Elford (London). Technical details of a complex procedure.—A strain of *Bact. ærtrycke*, with unusual epidemic characters, by W. W. C. Topley, M. Greenwood, and J. Wilson (London). Produces a widespread infection of a mouse population without causing a severe and fatal epidemic, and so results in a considerable degree of protection.—A new serological type of Salmonella, by P. H. Leslie and A. G. Shera (Oxford and Eastbourne). Isolated from a clinical example of paratyphoid fever.—The preparation of fractions of different antitoxic quality from the same serum, by M. Barr and A. T. Glenny (Beckenham). Successive fractionation with ammonium sulphate gives a series of antitoxic globulins with widely different in vitro/in vivo ratios.—Enzoötic hepatitis or Rift Valley Fever: an undescribed virus disease of sheep, cattle, and man from East Africa, by R. Daubney, J. R. Hudson, and P. C. Garnham (Kenya).—The chemotherapy of experimental streptococcus infections, by C. H. Browning, J. B. Cohen, S. Ellingworth, and R. Gulbransen (Glasgow and Leeds). Some anil quinolines have a decided effect in preventing and curing streptococcal infections in mice.—Staphylococcus toxin and antitoxin, by H. J. Parish and W. Clark (Beckenham). The reality of the toxin and the efficacy of the antitoxin are confirmed.—Further notes on Paget's disease of the nipple, by R. Muir (Glasgow). The condition is caused by the invasion of the epidermis by a carcinoma arising in the ducts or alveoli of the heart.—A new method of applying Nile blue as a fat stain, by T. Rettie (Edinburgh).—Obituary notices of C. Powell White (portrait) and John Anderson. Proceedings of the Society.

IN the issue of September, 1931 (vol. xxxiv., No. 5, pp. 597–700) W. Bulloch (London) gives a very interesting account, with a striking portrait of Shibasaburo, Baron Kitasato, the first Japanese bacteriologist, his devotion to Koch, his discovery with Behring of antitoxin, his identification of the plague bacillus, and his influence for good in his country.—Experimental renal disease produced by X ray, by M. S. S. Earlam and A. Bolliger (Sydney). Unilateral renal lesions produced by single exposures to X rays of medium wave-length consist of acute degeneration of the convoluted tubules; this is followed by scarring and some regeneration. X ray nephritis when well established is characterised by nitrogen retention, hypercholesterolæmia, polyuria, uræmia, and œdemia. A thorough anatomical and functional study which should be read in detail.—Primary cancer of the thymus with pluriglandular disturbance, by O. Leyton, H. M. Turnbull, and A. B. Bratton (London). A boy of 11 became fat and hairy; a man of 31 showed increasing fatness of the face, neck, and trunk. Both had diabetes mellitus, and at necropsy showed a small-celled medullary carcinoma of thymus with hypertrophy of the suprarenal cortex, functional hypertrophy of the thyroid, and fatty livers.—A further contribution to the knowledge of innervation of human tumours, by H. Oerte, H. Nye, and B. Thomlinson (Montreal). Affirms their previous conclusion that tumours really have nerves of their own (see p. 646).—On the existence of two forms of diphtheria bacillus —*B. diphtheriæ gravis* and *B. diphtheriæ mitis*—and a new medium for their differentiation and for the bacteriological diagnosis of diphtheria, by J. S. Anderson, F. C. Happold, J. W. McLeod, and J. G. Thomson (Leeds).—Obituary notices of J. Lorraine Smith (portrait), G. McCallum, and A. T. MacConkey (portrait).

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 19, 1931.

STRAITENED HOUSEKEEPING.

THE axe has fallen on medicine, in the first instance on the obedient necks of the 15,750 doctors in insurance practice who forgo on the average just under £50 each. On behalf of this group of practitioners the deputy medical secretary of the British Medical Association has intimated to Government health departments that they are prepared to bear their fair share of the burden which the community generally will be called upon to shoulder. This implies the acceptance of the reduction of the capitation rate by one shilling, as recommended by the May Committee, but not of the grounds on which this committee justified the reduction. The MINISTER OF HEALTH has stated in effect that the proposal for a percentage reduction is not based upon any doubt whether the present capitation fee is a just payment for services rendered; the grounds upon which it was based in 1924 remain unchallenged, and it is open to the Insurance Acts Committee to suggest its reconsideration at any time considered expedient. Rural practitioners will of course suffer more than urban ones from the increased duty on motor spirit, but they will not be subjected to reduction in the mileage grant. Representatives of the I.A.C. were assured that there would be corresponding sacrifice on the part of other bodies or persons concerned in the administration of national health insurance. Salaries in the public health services are not directly affected by this decision, but the MINISTER OF HEALTH in his circular dated Sept. 21st has intimated to local sanitary authorities that they should give all their officers the opportunity of sharing equitably in the sacrifice demanded by the national need, a euphemism which these authorities will not be slow to translate. They have it is true for the most part entered into binding agreement that certain scales of medical salaries would be maintained for five years from 1929, and if the present medical staffs do not ask to be regarded as a privileged group of local government officials, they are at all events entitled to expect uniform treatment over the whole country.

The public health doctor is likely to forget his personal sacrifice in his fear that social services may be imperilled through the cutting down of other expenditure by local authorities. He will be relieved that the circular, to which allusion has been made above, contains a sharply worded warning against any wholesale and ill-considered course of cutting down expenditure whatever its nature or purpose may be, though it enjoins the utmost care in making charges on the local rates, since the ratepayer and taxpayer are largely the same people. In making a survey of its expenditure the local authority is asked to pay special regard to whether the service is required on urgent grounds of public health. No one will quarrel with wise economy in administration and the strict supervision of every detail of expenditure, for as one of our correspondents remarks (p. 649), it is possible for big public departments to be grossly extravagant in small items, the cumulative effect of which is considerable. Some of our medical officers may positively enjoy the task of achieving efficiency in public health measures, for there are still many obsolete practices in high places, excused on the ground that public faith may not survive the scrapping of measures formerly enjoined. It may indeed be long since water-carts in London sprayed dilute permanganate on the streets, but routine house disinfection is a relic of epidemiological theory which we have long grown out of. It may be something of a fearful joy for the medical officer to be compelled by economy to discard such incubuses. Institutional life is proverbially uneconomical. It can of course never emulate the value which a canny and imaginative housewife with a growing family gets out of a minimal income, but here again there will be positive satisfaction in tightening up slackness. Another of our correspondents indicates some of the places where detailed saving can be effected without loss of efficiency. Many of the feeble old people in our public assistance institutions would get along well enough at home with a little extra assistance and oversight unless removed by the zealous official, and the same applies to many forms of chronic illness for which the constant attention of a skilled staff is not needed. This would release beds for hospital cases which would otherwise have to be provided at a large capital expenditure. In fever hospitals beds are too largely occupied in isolating mild cases of scarlet fever long after medicine has become aware that their isolation is powerless to affect the prevalence of disease in the community. Only a tithe of the money so saved would be required to put into effect the principles of preventive immunisation which are already achieving so much in the more enlightened communities.

We may not hope that the lean years will pass without the call for further sacrifice. Capital expenditure on repairs and renewals, if too long delayed, may assume large proportions and render impossible developments of the health service which showed great promise last year. It may require rigid determination to maintain what has already been achieved. And for this the coöperation of an intelligent public will be invaluable. Instruction in public health must go on, and with better times the full activities can be resumed, probably with better outcome as the reward of hard-won discrimination.

EPIDEMIC RABIES IN MAN.

THE last twenty years have been remarkable for the appearance, either for the first time or in forms of enhanced virulence, of diseases due to filtrable viruses, and especially those with a predilection for the nervous system. The outbreak and world-wide dissemination of epidemic encephalitis lethargica was followed only a few years later by the occurrence of large numbers of cases of post-vaccinal encephalitis, of encephalitis complicating measles, and of acute disseminated encephalitis of unknown origin. Resemblances were observed between the three last-named forms of encephalitis and the "neuroparalytic accidents" which had for many years been known to complicate the Pasteur treatment of rabies in man. In this issue Dr. E. Weston Hurst and Dr. J. L. Pawan report an epidemic of acute ascending myelitis which occurred in 1929 in the island of Trinidad, and which there is reason to believe was due to the virus of rabies. Seventeen natives, including members both of the East Indian and of the Negro races, were affected. The clinical picture was that of ascending paralysis, with loss of sphincter control, terminating fatally through paralysis of respiration. The pathological changes in the spinal cord were characteristic of rabies, though no Negri bodies were found. The disease proved transmissible to animals which exhibited both the symptoms of rabies and the characteristic pathological changes of this disease, including the presence of Negri bodies. A similar virus has been isolated from cattle in Trinidad. No direct mode of transmission from the cattle to the affected individuals has been discovered, nor was there evidence that they had been bitten by dogs. It is tentatively suggested that the disease has been conveyed from the cattle to man by the blood-sucking vampire bat, indigenous to Trinidad.

Ascending paralysis without mental excitement and pharyngeal spasm has long been recognised as a rare manifestation of human infection with rabies, and is the characteristic form of the disease in some animals, especially the bovidæ. An epidemic of this form of rabies in man has not previously been described, though R. Kobayshi[1] isolated a virus resembling that of rabies from a sufferer in an epidemic of encephalitis in Japan in 1924. There is some doubt, however, as to whether this virus should be held responsible for the epidemic. R. E. Knutti[2] has recently reported a case of myelitis in man, which he proved to be due to the virus of rabies, and in which the mode of infection could not be traced. The possibility of rabies infection must therefore always be considered in obscure cases of ascending myelitis or Landry's paralysis, even when there is no history of contact with a rabid animal.

As in the case of acute disseminated encephalitis complicating the exanthemata, controversy has arisen as to whether the "neuroparalytic accidents" which occur in the course of the prophylactic treatment of rabies should be regarded as due to rabies virus, or to some toxin injected with the vaccine, or to a previously latent neurotropic infection. Hurst and Pawan apparently reject the view that rabies is the cause, for they state that the "cases of paralytic rabies arising during or after antirabic treatment must be sharply differentiated from those of the so-called paralytic accidents in which the lesions, quite different from those of rabies, are identical with those in post-vaccinal encephalitis." It is doubtful, however, whether upon clinical grounds cases of acute ascending paralysis occurring during treatment for rabies can be sharply distinguished from acute transverse myelitis arising in similar circumstances. In both cases the period of incubation is shorter than that of rabies itself. Whether the pathological differences justify the assumption of a difference in ætiology may be doubted, especially as in Knutti's case both the white and the grey matter of the cord were extensively destroyed. P. Bassoe and R. R. Grinker,[3] who have lately compared the pathological changes in human rabies with those in rabies vaccine encephalomyelitis, point out that in many ways the rabies vaccine is analogous to vaccinia. They suggest that in both cases the encephalomyelitis which may follow the vaccination owes its peculiar pathological features to the fact that it is caused by an attenuated virus.

◆

IRREGULARITIES OF THE TEETH AND JAW.

Although Fauchard, in the eighteenth century, wrote about irregularities of the teeth and devised some simple forms of appliance for their treatment, yet the first contribution of importance to orthodontics was the book on oral deformities written by Norman Kingsley in 1879. Eight years later, with the publication of E. H. Angle's famous book on "Malocclusion of the Teeth," the science of modern orthodontics was definitely launched, for Angle provided it with a classification and a technique which, in a modified form, have remained an integral part of its teaching. Up to now the greatest advances in the subject have been along the lines of technique, for a succession of ingenious mechanical appliances of great delicacy have been devised for the purpose of moving misplaced teeth into correct alignment. Our knowledge of ætiology has been relatively scanty, though a mass of literature has been accumulated on the subject.

The latest contribution[4] is a volume by Prof. J. B. Brash, amplified from a series of four lectures delivered under the auspices of the Dental Board. Prof. Brash's previous work on the growth of the jaws, normal and abnormal, details original research. This volume represents a critical stock-taking of the extent of our knowledge of the causation of malocclusion, and shows discernment, as well as breadth of knowledge. We imagine that it will be long before it is superseded.

Many different theories have been propounded on the cause of irregular teeth; for no one theory could explain all forms of malocclusion, and the types of irregularity are numerous and varied. Certain well-recognised forms of irregularity seemed to have an obvious explanation. For example, the crowding of the premolars is attributed to premature loss of the milk molars, the separation of the upper incisors to a persistent frænum or to the presence of a supernumerary tooth, the gap between the upper and lower incisors to thumb-sucking. But these irregularities, though they may lead to impairment of function and facial disfigurement, are of minor importance. The gross forms of malocclusion, in which the whole of the dental arches are involved, are more puzzling. Certain constantly recurring types of malocclusion tend to fall into three groups: (1) generalised crowding, usually affecting both jaws, and characterised by narrow arches, high palate, and prominent incisors; (2) defective development of the mandible, accompanied by a receding chin and a prominence of the upper front teeth, which appears greater than it is because of the retrusion of the lower incisors; and (3) the underhung lower jaw, in which the lower incisors project beyond the upper teeth. These main types of malocclusion, which are serious both æsthetically and functionally, have given rise to much controversy. In the early days of orthodontics, attempts to explain irregularities of the teeth in terms of mechanical factors were common. Even such varieties as superior protrusion and inferior retrusion were attributed to local factors operating in childhood. Gradually it was realised that such explanations were unsound, and that while certain limited and sharply defined types of irregularity might be due to a mechanical factor, some other explanation must be sought for the more serious forms of malocclusion. The next stage in the history of orthodontics was the ascription of malocclusion to exogenous and environmental factors, such as adenoids and mouth-breathing, bottle-feeding, and rickets. For long the association between adenoids and both superior protrusion and mandibular retrusion was accepted by many authorities. Explanation of the genesis of contracted arches was simple and plausible. The pressure of the cheeks in mouth-breathing and the absence of the moulding action of the tongue, which should lie against the palate in nasal respiration, were factors which, according to this view, combined to push up the palate and buckle the nasal septum and so compress the dental arch. Unfortunately, this facile theory was found less acceptable as knowledge increased. M. H. CRYER showed that there was no constant relation between the palate and nasal septum, and that a broad arch could be associated with a deflected septum and vice versa. More recently, Prof. BRASH observed that the level of the palate descends as growth occurs, and that the high palate associated with contracted arches is due to an abnormal growth of the alveolar processes. This observation did much to cast doubt on the validity of the hypothesis that adenoids and mouth-breathing are the most important factors in malocclusion. Prof. BRASH concludes from a review of the evidence that "it has still to be proved that there is any significant correlation between the presence of adenoids and the incidence of deformities of the jaws and palate."

[4] The Ætiology of Irregularity and Malocclusion of the Teeth. By Prof. J. B. Brash, M.A., M.D. London: The Dental Board of the United Kingdom. 1931. 5s.

The more recent developments in orthodontic science have been in the direction of exploring the rôle of exogenous factors in malocclusion, such as heredity and disorders of growth. It is significant that whereas 20 years ago attention was chiefly focused on the permanent teeth, and the possibility of malocclusion in the milk dentition was passed over as both rare and unimportant, now the orthodontist devotes an increasing amount of attention to the milk dentition. A closer study has shown that malocclusion is common in this dentition, and therefore that the factors concerned in irregularities of the teeth must commence in early life. More recently attention has been paid to the possibility that deformities of the jaws are established during fœtal life. B. WEINBURGER, M. SCHWARZ, and others have shown that the condition of mandibular retrusion may be present at birth. The study of the inheritance of jaw forms and malocclusion has become imperative, and it seems likely to shed much light on the ætiology of malocclusion. Sir ARTHUR KEITH has established a strong case for the view that evolutionary tendencies of comparatively recent origin are tending to bring about profound changes in the shapes of the jaws and that some forms of malocclusion represent a disharmony in evolution. Prof. BRASH arrives at the conclusion that while there are "accidental" happenings to the jaws such as habits, mechanical factors, or recognisable pathological conditions, the explanation of malocclusion in general must be sought in inheritance, and that environment, though not negligible, is a complemental factor. The narrow attitude which looked upon irregularities of the teeth as a local condition with a local cause is thus being abandoned in favour of the view that the ætiology of malocclusion is part of a large problem which can only be solved on biological lines.

THE BRITISH ASSOCIATION.

As already announced in our columns, the centenary meeting of the British Association for the Advancement of Science will be held in London from Sept. 23rd to 30th. The installation of Lieut.-General J. C. Smuts, F.R.S., as president will take place next Wednesday at 3 P.M. in the Albert Hall, and at 9 P.M. on the same evening, at the Central Hall, Westminster, he will deliver his presidential address on the Scientific World-Picture of To-day. The meeting coincides with the celebrations commemorating the centenary of Michael Faraday, who, on August 29th, 1831, made the discovery of electro-magnetic induction. Delegates will be received at the Royal Institution in the afternoon of Sept. 21st and a meeting will be held in the same evening at Queen's Hall, when addresses on Faraday's work will be given by the Prime Minister, the duc de Broglie, Marchese Marconi, Prof. Elihu Thomson, Prof. P. Zeeman, Prof. P. Debye, Lord Rutherford, Sir William Bragg, and Lord Eustace Percy. On Sept. 23rd, a Faraday exhibition, organised at the Albert Hall by the Institution of Electrical Engineers, will be opened to the public. Special exhibits will demonstrate the full development of electrical and chemical science and industry which have their origin in Faraday's work.

ANNOTATIONS

DIFFICULTIES IN CERTIFYING MENTAL DEFICIENCY.

Part V. of the Education Act makes it the duty of the parent of a defective child to cause the child to attend a special school where one is available. The local education authority, if satisfied that the parent is not making suitable provision for the child's education, may require the parent to send the child to a suitable school. "If he fails without reasonable excuse to do so," the local authority may apply for a magistrate's order. The first question, of course, is whether the child is defective, not merely "dull or backward," to quote Section 55 of the Act, but "by reason of mental or physical defect incapable of receiving proper benefit from the instruction in the ordinary public elementary schools." A recent case, before the Taunton magistrates, failed because the medical witness could not agree upon the question whether the child was defective or not. The child was a girl of 13. The school medical officer for the borough (Dr. J. Allen) gave evidence that she was at least three years below the usual standard for her age. After an adjournment, apparently arranged in order to obtain further medical evidence, Dr. H. T. Aveline, superintendent of the Mental Hospital at Cotford, gave evidence that the girl read and wrote from dictation quite well, could calculate change satisfactorily, and was able to tell the time. He found her decidedly backward and dull in her answers to certain intelligence tests, and he thought her about a year behind her age; but he did not consider her certifiable as a feeble-minded person. He thought her capable of receiving benefit from the instruction in the ordinary public elementary school. Section 55 of the Act seems to require that such a child should be capable not only of receiving "benefit" but of receiving "proper benefit" in an elementary school. However that may be, the magistrates declined to order her to be sent to the Sandhill Park Institution at Bishop's Lydeard and dismissed the local authority's application with costs.

It is unfortunate when such proceedings are brought unsuccessfully. The refusal of such an application tends to encourage parents of other backward children in their very natural reluctance to send a child from home to a special institution. It is particularly unfortunate when the failure of the proceedings is due to diversity of medical evidence. Whether or not the variance was due to the fact that the superintendent of a mental hospital approaches a case from a slightly different angle from that of a school medical officer, it is a pity that medical standards of mental deficiency should be capable of representation as merely personal. Possibly consultation between medical witnesses would save the local authority from taking fruitless action or alternatively would enable the question of the child's deficiency to be referred to the Board of Education as may be done "in case of doubt" under Section 55 subsection (6) of the Act. Children suitable for special school education are usually certified before the age of 13; but there appear to have been special circumstances in the Taunton case, for it was stated that the girl had originally been certified by the county medical officer. Certification for purely educational purposes may some day be abolished if the recommendations of the Wood Report receive effect. The Taunton case will perhaps bring the day nearer.

STIFF JOINTS.

THE need to distinguish clearly between stiffness and true ankylosis before attempting to improve the mobility of a joint, or assessing disability, is emphasised by Dr. Laquerrière, Dr. Loubier, and Dr. Jaudel in a communication to the May-June issue of the *Revue d'Actinologie et de Physiothérapie.*[1] In true ankylosis the articular ends are united by bone or fibrous tissue, and these cases are outside the scope of physiotherapy. In cases of false ankylosis, or joint stiffness, as the authors prefer to call them, X ray examination shows the absence of bony union and the presence of a joint cavity. The stiffness may be due to a variety of causes, which must be investigated, but even after the condition has been correctly diagnosed the degree of improvement which may be expected to follow on a course of physiotherapy cannot be predicted. The authors' experience, that apparently similar conditions show marked differences in their reaction to physical treatment, accords with that of other observers. When the articular ends of the bones have undergone definite changes in shape, the possibility of effecting some improvement in function must be considered; the presence of a bony mass may frustrate any attempt to improve the usefulness of the joint by physiotherapy. In cases of joint stiffness following injury, when X ray examination is negative, thickening of the tissues surrounding the joint may sometimes be recognised on palpation. This thickening is at first due to œdema and congestion of tissues in the early stages of repair, and later to the development of fibrous tissue. In neglected cases, contraction of joint-capsule and ligaments, adhesions of tendons, atrophy of muscles, and, in old-standing cases, decalcification of the bone and atrophic changes in the cartilage, have destroyed the functional capacity of the joint. In their early stages extra-articular lesions respond favourably to physiotherapy; later, prolonged treatment may give some functional improvement. A pseudo-stiffness due to intra- or extra-articular causes of pain on movement must be recognised. It may be due to an inflammatory process or to the presence of loose bodies and fringes. In cases of stiffness due to cicatricial contractions of soft parts, where destruction of the tissues was not too extensive, the authors have recorded satisfactory results from radiotherapy and ionisation. The use of the constant current is recommended in the treatment of stiff joints because of its properties of allaying pain, improving the blood-supply, and diminishing œdema and vascular stasis. These authors claim for it also a trophic action and a mild fibrolytic action, which they attribute to the liberation of sodium ions in the tissues. Ionisation has given good results in their hands; iodine and salicylic ions are most frequently employed. Local ultra-violet irradiations are recommended for the improvement of tissue nutrition, and infra-red radiations as sedatives. Faradic stimulation and diathermy are also recommended.

Many of the cases reported by Dr. Laquerrière and his colleagues were first seen weeks, or even months, after the primary injury to the joint, at a time when the most profitable stage for physical treatment had passed. This neglect is not altogether unknown in this country, but fortunately most practitioners are beginning to realise that it is in the period immediately following the injury that the functional value of a joint should be safeguarded by adequate treatment. It is becoming more widely known also that the final disability does not depend entirely on the severity of the initial lesion. A momentary, or even an incomplete, separation of the parts of a joint involving tears in the capsule and ligament, and separation or tearing of the cartilage, is no longer regarded as a trivial injury. Rest, under conditions approaching most closely to the physiological requirements of the tissues, and approximation of the lacerated structures during the early stages of repair are now considered essential for the attainment of good functional results. Splinting, massage, active movements, electrotherapy and irradiation, all play their part in the attempt to establish the ideal conditions for repair. Rest, in the early stages of repair, inhibits the formation of excessive fibrous tissue and lessens the risk of the development of bone in the tissues surrounding the injured joint. Electrotherapy is directed in the early stages towards allaying pain, clearing up œdema, assisting the blood-flow, and warming the tissues. Massage, if it is gentle and superficial, relieves spasm. Subsequent treatment involves the maintenance of favourable local conditions of warmth and good blood-supply, and the encouragement of active movements designed gradually to increase the tone of the muscles, until ultimately full resumption of free voluntary movement is attained.

VITAMIN D IN IRRADIATED YEAST.

It is now pretty generally recognised that infants and young children, in temperate latitudes throughout the world, need routine antirachitic treatment at any rate in the winter; the incidence of rickets, even among breast-fed babies, is not negligible. In some ways, as A. F. Hess points out, modern science has provided us with an embarrassing richness of therapeutic materials for the purpose and there is also a very wide choice of means of administering vitamin D to the child. Shall we treat the human mother, or the cow from which the artificially fed baby gets its milk, or shall we treat the baby itself, and when we have decided this point, shall we use ultra-violet irradiation or shall we administer cod-liver oil or its unsaponifiable fraction, or irradiated ergosterol, or irradiated milk or irradiated yeast or any other irradiated material? If it is decided to administer the therapy to the human mother or to the cow, rather than to the infant, the fact must not be lost sight of that the mother herself may require the vitamin, and her body may in that case not pass it on to the child. Such therapy through the mother should not be relied on blindly; the milk should be tested biologically in order that one may be quite sure that the desired supplement really reaches the baby. In choosing the means of providing the vitamin to mother or child a number of points have to be considered, beyond the simple one of the antirachitic potency of the means chosen. There are questions of cheapness, of convenience, of palatability, and of possible toxicity; there is also the problem how best to obtain the mother's coöperation, or how to obviate the need of relying on it. The preparation and testing of an antirachitic material which meets most of the important requirements was described in our last issue by Mr. S. K. Kon, Ph.D. who has prepared dried yeast and rendered it potently antirachitic by irradiation with ultraviolet light. Tested on rats this irradiated yeast was found to cure rickets in a very small daily dose, while it retained its antirachitic potency for many months in a refrigerator or exposed to air at room temperature. It was found to be toxic for rats in an enormous dose, 15,000 times the minimal curative dose. A trial of it was made on rachitic infants in Warsaw[1] when a daily dose of 0·75 g. was found sufficient to cure rickets in babies. Hess[2] made trial of the milk of cows fed with a supplement of irradiated yeast; rickets was both prevented and cured in babies who consumed such milk. The above tests seem to show that irradiated yeast can provide a material which satisfies every requirement. It is cheap and convenient; it is not particularly palatable, but the dose needed is so small that the flavour can easily be disguised. If its use as a supplement to the diet of cows supplying nursery milk were made compulsory there would no longer be any question of the mother's coöperation being needed save in the purchasing of the right milk. Irradiated yeast is, however, at one disadvantage; it does not convey vitamin A together with its vitamin D, and every material which fails in this point must be ranked as inferior dietetically to cod-liver oil.

IRISH HOSPITALS AND TRAFFIC CASUALTIES.

While many provisions of the Irish Free State's proposed Road Traffic Bill resemble the Road Traffic Act passed at Westminster last year, Clause 156 contains interesting variations as to the reimbursement of hospitals. If the proposal becomes law, a hospital in the Free State will have an independent right of action against a negligent motorist to recover the expense of treatment of a victim. If a patient is received into hospital for treatment of injuries "sustained in such circumstances that the injured person is entitled or (if he has died) was during his lifetime entitled to recover from some other person damages for such injuries," then the person liable to pay such damages "shall also be liable to pay to the governing body of such hospital" damages measured according to the expenses incurred by the hospital in such treatment. The damages recoverable by the hospital are to be measured as follows: they are to consist of a reasonable sum for the treatment, subject to the deduction of any sums paid to the hospital by the patient. If the patient has been maintained in the hospital for treatment, the "reasonable sum" for maintenance is not to exceed the lesser of the two following scales—namely, (1) the rate of 9s. a day, or (2) the average daily cost of maintaining a patient in that hospital. The motorist's liability to reimburse the hospital will, it seems, be a risk to be included in the compulsory insurance policy. The cost will therefore fall on the insurance company which will naturally demand a higher premium. This machinery for reimbursing hospitals through the insurance companies has not been adopted in the English enactment, though the Road Traffic Act of 1930 may some day be altered in this respect if the insurance companies decide upon the extra cost of the additional cover, and fix a reasonable increase of premium.

The main point on which lawyers are likely to concentrate is that the proposal enlarges the normal scope of a contract of insurance. A, a motorist, agrees to pay an annual sum to B, an insurance company, in order to obtain protection against third-party risks. But, if the clause becomes law,

---

[1] Kon, S. K., and Mayzner, M.: THE LANCET, 1931, i., 794.

[2] Hess, A. F., Lewis, J. M., and Thomas, B. H.: Jour. Amer. Med. Assoc., 1931, xcvii., 370.

Y, a hospital, will be entitled to sue A for injuries to Z, the victim of a traffic accident. It may be noted that the new clause will only apply to accidents where the motorist's negligence is established. The hospital, therefore, will not only have the trouble of conducting actions against possibly elusive motorists in whatever may be the Free State equivalents of of our county courts and High Court; it will also have the whole expense of the proceedings if the proof of negligence fails; and it will need to keep in touch with its patients who may be wanted as witnesses months after they are discharged from the wards. The contingency of the patient's death from injuries is provided for; is it clear what happens if the motorist dies? The clause will benefit the hospitals by enabling them to sue where otherwise they have no legal remedy. But there are many traffic accidents where negligence either is not, or cannot easily be proved to be, the cause; allegations of negligence—not to mention allegations of contributory negligence—are often strenuously fought. The hospitals therefore may have bought their new remedy at the price of a string of law suits. Meanwhile, the existence of a system of compulsory contribution to a hospital may disincline both motorist and patient to make any direct and voluntary payment.

NERVES IN TUMOURS.

If the diversity of growths which we classify together as tumours can be said to have any one feature in common it is their functional dissociation from the rest of the body. Anatomically this dissociation has commonly been held to be represented by the absence both of coördinated blood-supply and of nerves. In fact, some tumours have been shown to be surrounded and permeated by a newly formed system of capillary vessels, and even if we look on this development as part of the connective tissue reaction aroused by the tumour, the effect is that the tumour does obtain some of the oxygen which it needs. Something of the same kind may also be true of nerves. Awhile ago Prof. Hurst Oertel, of Montreal, urged that in some cases nerves could be demonstrated in tumours ending in such intimate relation with the parenchyma that their essential nature could hardly be doubted. In the *Journal of Pathology and Bacteriology* for September he returns to the subject with fuller technical details and more ample illustrations, mostly from cancers of breast. It is exceedingly difficult to be sure what the appearances seen and pictured really represent. They certainly look like nerves and nerve-endings, but the silver impregnations by which they have been obtained are liable to behave in curious ways, and it is possible that the findings in tumours are not nerves at all. And again, granting that they are nerves, it may be that they are residua of the tissue invaded by the growth or irritative responses in the neighbouring connective tissue, such as have been amply demonstrated in mouse tumours. On the whole, however, we should be inclined to accept the conclusions to which Prof. Oertel's long inquiry into the subject has led him, and agree that he has demonstrated that some tumours have a nerve-supply to or from the tumour cells themselves. This is by no means the same as saying that all tumours have nerves; nor are Prof. Oertel's findings at any real variance with those of, for example, Dr. Ludford, who has searched for nerves and failed to find them. We gather that Prof. Oertel himself has failed much oftener than he has succeeded. This is, in fact, about what we should expect on general grounds; tumours grade almost imperceptibly from normal tissues to the most bizarre and monstrous formations, and they have no general rules to which there are no exceptions. It would be natural for some of them to have nerves and others none, just as some of them probably have blood-supplies of their own, while others do not. Functionally, tumours of the thyroid, anterior pituitary, suprarenal cortex, parathyroids, and islands of Langerhans may be so related to the body that they produce the obvious effects of excesses of their internal secretions; anatomically, certain tumours may well have some simulacrum of the normal arrangements.

LOSS AND GAIN OF HOOKWORMS.

Hookworm infections are happily of limited duration. Those who have had no chance of reinfection for six or seven years rarely pass the eggs of these parasites, and worms are, for the most part, completely absent after this period. These facts have been known since the early days of hookworm investigations, and observers have been concerned chiefly with the rate of the diminution of infection. Egg counts made on prisoners in India by C. F. Fearnside in 1900, and in Burmah by P. K. Tarapore, in 1913, suggested that the diminution was gradual. This, too, was S. T. Darling's opinion on realising how slowly Tamils in Batavia added ancylostomes to the load of necators which they had brought with them from India; his facts were obtained by counts of worms recovered after anthelmintics, and in his conclusion the belief is implicit that in any country the average worm load is fairly constant, and that gain and loss run parallel. But Darling measured only the balance between gain and loss, which is no necessary measure of the rate of either; while in the investigations on prisoners it was assumed that any opportunity for gain must have been absent or nearly absent.

Assuming a fairly constant average worm load among prisoners admitted to a Calcutta jail, A. C. Chandler[1] satisfied himself by egg counts on the stools of men who had been in prison for varying periods that, following their admission, there was a rapid initial and a later gradual fall in the number of eggs passed; and he claimed that his conclusions were supported by the curves obtained by K. S. Mhaskar,[2] who treated men who had been in a Madras jail for varying periods and counted the worms passed. P. A. Maplestone,[3] however, working in the same jail in which Chandler had worked, obtained quite different results. His method was the more satisfactory, comprising monthly egg counts on the same men throughout a year. His average counts showed no fall in egg numbers as imprisonment lengthened. On the contrary, there was a seasonal variation, with a maximum in May and a minimum in October. He pointed out that some prisoners in this jail were employed in extramural work, so that the occurrence of fresh infections could not be excluded. Maplestone's early and late figures were not, however, strictly comparable, for men were leaving the jail steadily and the fraction which remained throughout, and alone furnished the later figures, may not have had the same original average egg count as that given by the total number with which the investigation began.

[2] Hookworm Infection and Sanitation, Ibid., 1920, viii., 398.

[3] Seasonal Variation in Hookworm Infection, Ibid., Oct., 1930.

G. C. and F. K. Payne[4] have since attacked the problem from another angle. They point out: (1) that, accepting Chandler's curves, an infection of 1000 worms must be accompanied by an average loss of 40 worms a week during the first three months after infection ceases to be acquired, with the bulk of the loss concentrated in the early part of the period; (2) that this considerable loss should be easily detected both by recovery of worms from the stools and by a lessened egg content of the stools. In order to investigate this point they took into hospital two persons whose egg counts showed them to be heavily infected, and observed without treating them for 16 and 19 days respectively. During this period scrupulous personal examination of all stools revealed two worms only in one case, and one only in the other, while in neither was there any discernible lessening of the number of eggs passed. Since, after treatments, these persons voided over 3000 and 1350 worms respectively, and even then were not quite free from infection, the number of worms passed in the pre-treatment period was about 1 per cent. of that required if Chandler's curves held in conditions other than those obtaining at the beginning of imprisonment, with whatever this implies of preliminary anxiety, and subsequent alterations in diet and mode of life. Recent experience is, then, against the conclusion that in ordinary conditions hookworms are rapidly lost after infection. Rather is the older conclusion correct, that the loss is slow and gradual, some parasites persisting for six or seven years. Treatment should not, then, be withheld in the expectation that, by natural loss of worms, the load of infection will rapidly be reduced to a figure which a certain phase of opinion holds to be negligible. The rate of gain of hookworms by any man will, of course, vary with the misfortune, or sanitary misbehaviour, which brings his skin into contact with some heavily infected spot.

RURAL AND URBAN DEATH-RATES IN FRANCE.

IN a report communicated by Mr. Marcel Moine, the statistician, to the standing committee of the Office International d'Hygiène Publique, and published in its *Bulletin* for August, some instructive comparisons are made between the death-rates of the country and the town. This study does not include the whole of France, but only certain rural and urban districts, the period under review being the year 1928. It was found that the 114,199 deaths in the urban group were equivalent to a death-rate of 15·3 per 1000, whereas the 42,664 deaths in the rural group were equivalent to a death-rate of 17·8 per 1000. In the same year the death-rate for the whole of France was 16·5 per 1000. Up to the age of 19 the death-rate was considerably higher in the urban than in the rural groups, but between the ages of 20 and 39 the reverse was the case, and in the oldest age-group the death-rate was higher in the rural than in the urban group. Such diseases as those of the heart and kidneys, which do not take a heavy toll of life before the age of 40, were found after this age and for the rest of life to be much more frequent as causes of death in the urban than in the rural group. As for the diseases of the respiratory system other than tuberculosis, the mortality therefrom was definitely higher in the urban group up to the age of 10, and again after the age of 45. Between the ages 25 and 49, the proportion of deaths by violence was higher in the rural group. In the urban group it was the rule for the deaths to be notified by a qualified practitioner, whereas this was the case in only 40 to 76 per cent. of the deaths in the rural areas. There were however two rural areas in which 99 and 90 per cent. respectively of the deaths were notified by a qualified practitioner. It would therefore seem that there should be no insuperable obstacle to this practice becoming general throughout country districts.

OCCUPATIONAL HAZARDS OF CHROMIUM PLATING.

THE discovery of chromium plating has brought with it some new occupational risks. These are explained in a recent article by Dr. A. Langelez.[1] He explains that metal objects to be plated are suspended in a bath of chromic acid, and the large volumes of hydrogen released from the cathode carry with them into the air a brownish fog of the atomised liquid. This vapour may damage the skin, the mucous membranes, and the eyes. The skin lesions vary considerably, sometimes taking the form of erythema, sometimes of superficial burning, and in certain predisposed subjects, especially those who perspire freely, of eczematous dermatitis. The fluid is said to have a caustic action on injured skin, producing a hard and painful ulcer, which may penetrate the bone, and has earned in Belgium the name of *rossignol* or *pigeonnau*. These chromium holes, already familiar among chemical workers in chromium compounds, are now encountered among workmen in chromium plating. The ulcers are particularly frequent in the interdigital spaces, the borders of the nails and the knuckles; they progress slowly, and will not heal while the patient is still in contact with the chromium. Treatment is identical with that of burns. The only method of protection hitherto attempted has consisted of long rubber gloves, but even if these remain intact, the continual perspiration is not good for the skin. A dressing is being tried, composed of one part of lanoline to three of paraffin; this is washed off after work, and the affected parts are bathed in a mixture of commercial alcohol one-quarter, hydrochloric acid one-quarter, and water one-half. Some authorities recommend a wash in 2 per cent. sulphate of iron. The results obtained from these applications have not yet been reported; ancillary measures include the use of indiarubber aprons and suitable footgear.

Chromium dust, as encountered in chemical works, is said to form chromium oxide on the cornea between the eyelids; the deposit appears as a brown discoloration, and ultimately impairs the vision. Vapour will not produce this effect, but if the liquid is accidentally splashed into the eye or rubbed in with a finger it may cause burning and ulceration of the cornea, with irreparable damage. This danger may be averted by properly designed goggles. Chromium seems also to have a peculiar affinity for the nasal mucosa, and characteristic lesions occur among those exposed to the vapour. Besides a chronic coryza, a number of workers suffer from an injury of the septum, the site of election being at the level of Jacobson's organ. According to Dr. Langelez, the mucosa atrophies slowly, grows pale and ulcerates, and the cartilage perforates in a few days to a diameter of ½ cm. to 1 cm. In some cases there is considerable phagedæna. This lesion is painless, and does not interfere with nasal function; some workers do not know that they have been attacked until they are medically examined. If the patient leaves work, the injury scars over in a month or two. Manufacturers are now using aspirating apparatus to draw off the noxious vapour, and the workers are being advised to block the nostrils with cotton-wool soaked in paraffin, tincture of myrrh, or silicic acid. The latter precaution, however, makes mouth-breathing inevitable, and facilitates the absorption of the vapour. A respirator would get over the difficulty, but its prolonged use is tiresome, and workers are not easily induced to submit to it. It is possible to protect the nasal mucosa with a film of zinc oxide or balsam of Peru. If chromium plating has come to stay, this new hazard will demand close attention.

UROSELECTAN AS A RENAL EFFICIENCY TEST.

SINCE the introduction of excretion urography methods for the radiography of the kidneys, the possibilities of this technique as a means of estimating renal efficiency have been widely considered. Uroselectan, which was the dye first introduced for outlining the pelvis of the kidney radiographically, contains 42 per cent. by weight of iodine and is thus opaque to the X rays in quite dilute solution. It has a very high specific gravity and is excreted almost entirely in the urine, though there is probably some slight elimination through the liver as well. Given intravenously it is almost completely non-toxic, though it causes some fall in blood pressure and more serious risks in patients with badly diseased livers. A. V. Lichtenberg, who has been in the main responsible for the introduction of excretion urography, did not anticipate that uroselectan would be of service in the investigation of renal function,[1] but it appears that the excretion of uroselectan shows a relatively close relationship to the excretory powers of the kidney in general. The presence of uroselectan in the urine is shown by an increased specific gravity, which may rise to as high as 1060 some three to four hours after the injection, or by its precipitation with acid, or by the iodine reaction with starch solution. With seriously diseased kidneys for instance the dye is so badly excreted that only a poor shadow or no shadow at all can be seen by the X rays. With healthy kidneys the excretion is rapid and complete and, since the dye is non-toxic and passes unchanged from the body, no harm to the kidneys results.

Drs. L. Villa and P. Introzzi[2] have recently proposed a technique for the use of uroselectan as a renal efficiency test in medical diseases of the kidney. Their method is briefly as follows:

> A catheter is passed in the morning whilst the patient is fasting, and the bladder emptied; the specific gravity of this specimen of urine is noted. The catheter is left in position and the patient then drinks 300 c.cm. of water; in 15 minutes the urine is drawn off and its specific gravity again recorded. A solution of 10 g. of uroselectan in 30 c.cm. of distilled water is then slowly injected intravenously, some two to three minutes being taken in the procedure. After the injection the urine is collected every two to three minutes for about 20 minutes, and then every 15 minutes for a further period of one hour. The catheter is then withdrawn, but all urine passed until the following morning is saved (for the first six to ten hours in two-hourly portions). Ordinary food may be taken during this time. The volume and specific gravity of the urine in the specimens is noted and the presence or absence of free iodine is ascertained by a simple test, using starch as indicator. In normal cases the iodine reaction first appears in the urine excreted between the second and third minute after the injection and reaches a maximum in that excreted during the next six to eight minutes. Excretion of iodine continues for between four to eight hours. The specific gravity of the urine after the patient has drunk the water falls low and after the uroselectan injection rises from 1001–1003 to 1006–1008 in four minutes, 1015–1016 in seven to eight minutes, and 1020–1022 in 12 to 14 minutes. At this height it remains for some 15 to 30 minutes.

The amount of urine excreted is *higher after* uroselectan than after simple water drinking without injection of dye. The test therefore estimates particularly the speed of excretion, as well as the degree of excretion of the dye. The authors consider an initial appearance of the iodine reaction later than five to six minutes after the injection of uroselectan as pathological, and a persistently low specific gravity or a delayed rise as having a similar significance. The total duration of the excretion they view as less important. They believe that this test will detect renal function deficiency whilst other tests are still negative; and it has the further advantage that the total time required is only some two to three hours.

Uroselectan shares, with other dye tests, the theoretical disadvantage of being an abnormal substance for the kidney to excrete, and of giving information only as to the capacity of the kidney to eliminate this substance. It is not proved with certainty that this capacity always runs parallel with capacity to excrete other substances. It is, moreover, not yet certain that the rate of excretion is a factor that is affected earlier in kidney disease than, let us say, the quantity excreted. The fact that large doses of uroselectan as given, for example, for intravenous pyelography may have serious consequences in cases of serious renal insufficiency, and even fatal results in the presence of such a condition as polycystic kidney, need not necessarily condemn the test, since Drs. Valli and Introzzi use smaller doses than is customary for radiological purposes. The multiplicity of renal efficiency tests however, together with the realisation that large portions of kidney tissue may be entirely destroyed before any defect in function is evident, has led to some doubt whether any dye excretion methods have much value. Whether this one is more delicate than its predecessors remains to be established.

A HOSPITAL AMBULANCE.—The Newcastle-on-Tyne West End Charities Committee has presented its ambulance to Newcastle Infirmary, the growth of other facilities having rendered it unnecessary for the committee to continue its own ambulance service.

TUBERCULOSIS POST-GRADUATE COURSE.—The Joint Tuberculosis Council has arranged a course of study to be held in South Lancashire from Monday, Oct. 19th, to Saturday, Oct. 24th. The course will open at 2 P.M. on Monday afternoon at the Tuberculosis Dispensary, Hardman-street, Manchester, when Dr. G. Lissant Cox and Dr. D. P. Sutherland will discuss Central Administration. On Tuesday, at 10 A.M., Dr. G. Jessel will give demonstrations at the Tuberculosis Dispensary and Light Centre, Eccles, and at 2.30 P.M. Dr. H. G. Trayer will deal with pathology and the problems of hospital treatment at the Baguley Sanatorium, Altrincham. On Wednesday, at 10 A.M., at the Manchester Dispensary, the subject of Pneumoconiosis in Stone-masons will be considered by Dr. P. Heffernan, in Miners by Dr. A. Pask, and in Cotton-operatives by Dr. G. Fletcher. At 2.30 P.M. Dr. Jessel, at the Peel Hall Pulmonary Hospital, will cover such matters as Lipiodol, Artificial Pneumothorax, Sanocrysin, and Blood Sedimentation in diagnosis and treatment. On Thursday, at 10 A.M., Dr. P. Edwards, at the Manchester Dispensary, will deal with Artificial Pneumothorax and Allied Therapy. The items will include visits to the East Lancashire Sanatorium, the Village Settlement at Barrowmore Hall, and a round-table conference and discussion on the Saturday morning. Information from Dr. W. Brand, hon. sec. for post-graduate courses, 8, Highway Court, Beaconsfield, Bucks.

SPECIAL ARTICLES

ECONOMY IN THE SOCIAL SERVICES.

REPRESENTATIVE VIEWS.

IN Circular 1222, issued on Sept. 11th by the Ministry of Health, local authorities are asked immediately to subject to careful and detailed scrutiny the whole field of their expenditure, examining for example whether full value is being obtained for money spent, what savings can be made in the administrative machine in all its branches, and whether development of any services cannot safely and properly be slowed down till better times. Notice has been too short for any wide consultation of medical officers to these authorities, but we have obtained the first thoughts of some administrative heads of large medical departments, of which two samples are set out below. For obvious reasons these views, and any others which may reach us from similar sources, are anonymous, and on all sides criticism and discussion will be welcome.

I.

My view is that saving might include a drastic review of all capital expenditure scheduled for this and next financial year. Many authorities were intending to spend large sums of money on institutions transferred from the guardians, and it is difficult for them to resist demands from technical staffs for new wards, laboratories, staff quarters, equipment, apparatus, and so forth. I am certain that most of this expenditure can be postponed without irreparable loss, and in fact with some gain if it implies a review of existing accommodation.

Each service should be reviewed with an eye to adjustments making for more economical working rather than the cutting out of any particular activity. In institutions in particular a good deal of saving should be possible in the aggregate by supervision of such items as (*a*) water, electricity, gas, telephone; with comparison between the various sections. (*b*) Laundry arrangements, where the allowance is too lavish either for wards and staff. (*c*) Food wastage, with control of refuse from kitchens and wards. Staff diet to be not above the standard of an ordinary middle-class household. (*d*) Fuel, its proper use. (*e*) Stores, drugs, appliances, chemicals, dressings; with comparison of wards and methods of checking. (*f*) Routine of duties of each member of staff to be checked individually.

Disinfection of houses after infectious illness might well be reduced substantially in most cases in favour of a thorough spring-cleaning. Drain-testing as a routine after cases of infectious disease, which is still often done, is sheer waste of time and energy.

Economies might be made in the use of hospital beds. (*a*) Far too many mild cases of scarlet fever are admitted to fever hospitals instead of being nursed at home. Scarlatinal serum can be supplied to practitioners to minimise complications. (*b*) A considerable proportion of the cases of diphtheria sent in by practitioners to hospital are not clinically diphtheria. They are often sent out on or about the tenth day, but even this is too long. (*c*) Public assistance institutions for acute or chronic sick, aged or infirm, might be greatly relieved if district medical officers were not so ready to send patients into institutions instead of continuing treatment and supervision at home. An increase in medical and relieving officers to meet their requirements would pay handsomely. Institutions cannot at present refuse to accept patients sent in by the relieving officer, many of whom would prefer to remain at home with a little help. (*d*) Colonies and schools for mental defectives tend to become too elaborate, too luxurious, and too technically staffed, and the same is true of nursery schools. I do not think these should be cut out, but they should be run with a more modest eye.

Much of the work under the Food and Drugs Acts could be cut out if the Ministry of Health would lay down more drastic standards and conditions of food preparation.

At infant welfare centres the machinery should be overhauled to see whether each member of the staff is pulling full weight. The supplying of milk, fresh or dried, through such centres is a grave waste of energy and damages their value as advisory centres. If mothers were referred for foods to the public assistance there would be less temptation to trade on the local authority. Much time is wasted by health visitors or school nurses in calling twice or more on cases of minor infection reported from school; the first visit to detect, the second to release for school. The leaving at the first visit of a slip with date for return entered by the health visitor would save time for more important work; parents helped by attendance officers rise quite well to their responsibilities.

To summarise. The lines of action seem to be: the saving of bricks and mortar; careful review in detail of each service, with pruning everywhere rather than cutting out any one section; particular regard to extravagant administration of institutions; the need for the staff to remember what would be their own standard if they were living on their own income at home.

II.

The proposed cut of £150,000 in the direct cost to the Exchequer of public health work reflects only to a very slight extent the cuts which it is anticipated local authorities will make, in view of the fact that the Local Government Act of 1929 abolished percentage grants for most of the public health services, consolidating these grants in a block grant in which the new budgetary proposals make no alteration. This means, of course, that savings effected by local authorities will not appear as any reduction in Government expenditure. The only services directly administered through health departments which remain on the percentage grants, and cuts in which will therefore appear in the £150,000, are the port sanitary service and the school medical service. Fifty per cent. of any savings in the former cannot amount to much, but school medical inspection and treatment are expensive. If it is proposed to slow up housing schemes this would account for a substantial proportion of the £150,000.

Circular 1222 points out that other local government officers should in equity share in the reductions which the Government have been able to impose upon teachers and the police. Such reductions will, for the reasons given, make little difference to the Exchequer, but will, if they are in anything like the same proportion, effect substantial economies in local administration. A large proportion of the expenditure of public health departments is attributable to salaries, and that must apply to all service which depend mainly on personnel and not so much upon occupation of premises and provision of goods.

As regards the relative value of the different medical services, there will be great variety of opinion. Nearly all of them are of recent establishment, and aim at conserving and improving the health of children and teaching them how to lead healthy lives, so that they may reach adult life fit to enter employment and capable of looking after their own health when they have left our hands. It will take a generation to tell whether these services have done what they set out to do, and even then the picture will be confused, because of the effect upon health of fluctuations in the standard of living. All we can say is that they are doing something to meet a need which has been obvious for many years, not only to the medical profession, but also to every thinking member of the community, and that it can be demonstrated in individual cases that they are doing good. In some areas, perhaps many, measures have been adopted which are not worth the money spent on them.

Special schools for the mentally defective are expensive, and would become a serious item of expenditure if they were sufficiently developed, as they are not in most areas. They are, however, serving not only the purpose of educating defectives, but, more important still, of removing from ordinary school classes children who are a terrible drag on their work. Many people would be surprised to learn the extent to which definitely defective children who have been taught in these special schools are employed and doing good work even at this time of grave unemployment. Indeed, there is something in the methods of teaching adopted in these schools which I hope will convey a lesson applicable to the ordinary school child.

I should rather see a pound or two saved here and there on our services than the crippling of any one of them. It has been my view for many years that too much emphasis has been laid upon housing in relation to ill-health, and that more has been spent on housing than we can afford. In view of the provision which has already been made by local authorities, and the certainty that the population will shortly be on the down grade, I think expenditure on housing should receive careful scrutiny.

I should not be sorry if shortage of money forced us to reconsider some of our well-established practices in relation to the control of acute communicable disease. Disinfection could certainly be cut down without disastrous results, but as an item of expenditure it is comparatively trivial. Child welfare centres for healthy children cost very little, and their work is of the genuinely preventive kind, which I think it would be most unfortunate to discontinue. We spend a great deal too much money on the hospital isolation and treatment of scarlet fever, because the medical profession and the public have come to expect it. In order to deal with epidemic fluctuations of this disease, we retain a number of beds and a considerable staff, which costs money. Moreover, we isolate and treat a very large proportion of all the cases of diphtheria, however mild, which occur in towns, because we cannot risk allowing a disease which has still a considerable percentage fatality to spread among the children in populous areas. Diphtheria immunisation, and possibly also scarlet fever immunisation, although they are not all that America has led us to believe, are of a sufficiently proved prophylactic value to merit their adoption on a much larger scale than they have been practised in this country.

The national maternity scheme will now be definitely suspended, and, I think, without serious hardship. The proposal was merely a consolidation of measures already taken piecemeal. I do not think that midwifery will suffer immediately to any material extent as the result of its postponement. In any case it was bound to be a matter of many years before any such scheme became efficient.

To sum up, I am all out for economy in administration, and strict supervision of every detail of expenditure. It is possible for big public departments to be grossly extravagant in small items, the cumulative effect of which is quite substantial. Some local authorities approach public health administration from a sentimental, rather than a business, point of view, and a medical officer encouraged in this way is not likely to concern himself much about details of costs. If I had to recommend curtailment of expenditure on any one branch of my work, I should be inclined to select the institutional segregation of mental defectives.

A STUDY OF CONTACT INFECTION IN TUBERCULOSIS.

By H. Midgley Turner, M.D., D.P.H. Manch.,
CLINICAL TUBERCULOSIS OFFICER TO THE CITY OF SHEFFIELD; LECTURER IN TUBERCULOSIS, SHEFFIELD UNIVERSITY.

An outline of the investigation upon which this paper is based has been given in a previous communication.[1] That contained the actual results of gross tuberculous infection among 833 contacts of the 185 households of fatal sputum-positive cases of phthisis which were investigated in North Worcestershire. It is my intention here to carry the analysis somewhat further, in an attempt to estimate the part played by various factors in the ætiology of the secondary tuberculosis which occurred in this group of house contacts.

1. SEX OF THE CONTACT.

Table I.—*Contacts of the Age-group 0–5 Years.**

Children 0–5 years.	No.	Death-rate per 1000 ; all causes.	Tuberculosis death-rate per 1000.	Total tuberculosis incidence per 1000.
Male	85	200	94·1	188·2
Female	71	211·3	42·3	183·1

Table I. shows that the sex of the contact seems to have little influence upon either the death-rate from all causes or upon the total tuberculous incidence-rate. The tuberculosis death-rate is, however, significantly heavier among male infants. Female children appear to resist the disease better than male children up to the age of 5 years, but a conclusion is hardly justified on account of the small number of deaths involved.

The results shown in Table II. allow of the following conclusions :—

(1) In the age-groups 5–15, 15–25, and 35–45 years, the phthisis incidence-rates are greater among females in sputum-positive households than among males. (2) Among contacts over the age of 45 in sputum-positive households the phthisis incidence-rate is

---

* In order to avoid a statistical fallacy, the 0–5 years age-group of contacts has been dealt with by a special method. The reasons for this method and the method itself have been outlined in a previous communication.

greater among males than among females. (3) The phthisis death-rate is significantly greater among female contacts up to the age of 25 than among male contacts. Over this age the male death-rate from phthisis is greater than the female death-rate. (4) The greatest death-rate and the greatest incidence-rate from phthisis among female contacts fall in the age-group 15–25. (5) The greatest death-rate from phthisis among male contacts is found in the 15–25 age-group, but the greatest incidence-rate occurs in the age-group 25–35. (6) Among contacts over 5 years old the incidence of phthisis is greater among females than among males in the ratio 100 : 70. The death-rate from phthisis is also greater among female contacts over 5 years than among contacts of the male sex over 5 years, in the ratio 100 : 84.

TABLE II.—*Tuberculosis Morbidity and Mortality Among House Contacts Over 5 Years of Age.*

(Rates per 1000 contacts in each sex age-group.)

Age-groups.	A. MALE CONTACTS.					B. FEMALE CONTACTS.				
	Contacts.	Death-rates.		Incidence-rates.		Contacts.	Death-rates.		Incidence-rates.

N.P.T. = Non-pulmonary tuberculosis. P.T. = Pulmonary tuberculosis.

Thompson[2] said: "If we once grasp the idea that the male has a superior power of resistance to attacks of phthisis than the female, we shall experience no difficulty in understanding the apparent anomalies in family phthisis." It may be suggested that the heavier incidence of phthisis on female contacts is due to their greater domesticity and consequent increased intimacy of contact, and not to any constitutional inferiority in resisting power. This may be a factor, but it is significant that over the age of 45 the phthisis-incidence is greater among men than among women in these sputum-positive households, for women do not become less domesticated after the age of 45 is reached. I suggest that the greater susceptibility of the female to gross contagion in the home during her active sexual life can be explained by application of the theory of allergy.

During menstruation there is a depression of the allergic state (as measured by tuberculin skin reactions); this also obtains during pregnancy and parturition (Baldwin, Petroff, and Gardner[3]). Thus an infected female between the ages of 12 and 45 is continually undergoing cyclical variations in allergy, whereas a male continuously exposed to gross infection has a gradually increasing degree of allergy. At the menstrual period the female can be infected by a smaller dose than the male. *Two weeks later she will now react to tubercle bacilli more vigorously than the male.* Such an alternation is likely sooner or later to produce manifest *disease*.

This application of the theory of allergy would explain the greater susceptibility of the female during active reproductive life. It would also explain why active tuberculosis rarely shows itself until the puerperium. During pregnancy the degree of allergy is lowered, so that the pregnant woman is easier to *superinfect, but is less likely to react vigorously to* superinfections. In the puerperium the rise in the degree of allergy initiates reactions round foci of *tubercle bacilli* which previously did not provoke *reactions, and manifest* disease may result from these reactions.

It must be recognised that this is pure theory, but I feel that it has the merit of allowing some visualisation of the possible processes at work.

2. SEX OF THE PRIMARY SPUTUM-POSITIVE CASE.

Table III. affords the following conclusions:—

(1) Among contacts up to the age of 15 in an infected household the tuberculosis incidence and the death-rate are greater where the source of infection is a female than where the source of infection is a male. (2) Contagion in a household is equally dangerous to contacts between the ages of 15 and 35, whether the infectious case is a male or a female. (3) The evidence is suggestive, but not conclusive, that among contacts over the age of 35 the tuberculosis incidence is greater where the infectious case is a male than where the infectious case is a female.

TABLE III.—*Rates per 1000 in each Age-group.*

Age-group.	Contacts of male infectious cases.			Contacts of female infectious cases.		
	No. in group.	Tb. D.-R.	Tb. I.-R.	No. in group.	Tb. D.-R.	Tb. I.-R.
0–5	94	53·2	106·4	62	96·8	177·4
5–15.. ..	97	10·3	103·1	73	27·4	178·1
15–35.. ..	163	49·1	128·9	147	40·8	142·8
35–up ..	133	7·5	67·7	122	8·2	49·2

Tb. D.-R. = tuberculosis death-rate. I.-R. = incidence-rate.

AGE OF THE PRIMARY SPUTUM-POSITIVE CASE.

The age of 35 was selected as a dividing line; thus the contacts are divided into two groups. The first group, A, is made up of contacts in households where the sputum-positive case was under 35 years of age at death. The second group, B, is made up of contacts in households where the sputum-positive case was aged 35 years or over at death.

TABLE IV.—*Rates per 1000 in each Age-group.*

Age-group.	A. Contacts of cases under age 35.			B. Contacts of cases over age 35.		
	No. in group.	Tb. D.-R.	Tb. I.-R.	No. in group.	Tb. D.-R.	Tb. I.-R.
0–5	90	77·8	166·7	66	60·6	90·9
5–15.. ..	89	22·5	134·8	81	12·3	135·8
15–35.. ..	197	40·6	162·4	113	53·1	88·5
35–up ..	170	11·8	47·1	85	—*	82·4

—* = No deaths.

It will be noticed in Table IV. that contacts under 35 years' old suffer a significantly greater tuberculosis incidence when the infectious case is also under 35 than where this case is over 35. On the other hand, contacts over 35 suffer a heavier tuberculosis incidence when the primary case is also over 35. It also appears that, in the aggregate, sputum-positive cases to have a bona-fide belief that no licence was required, the summons was dismissed under the Probation of Offenders Act on payment of three guineas costs.

The compulsory licensing provision does not apply to establishments carried on by registered medical practitioners who comply with certain prescribed formalities, nor to recognised hospitals and infirmaries; there is also an exception for hairdressers who give face or scalp massage or manicure treatment to female customers. An applicant for a licence must state his or her name, age, nationality, and technical qualifications as well as the nature of the proposed establishment and the business to be carried on. Some years ago scandals in connexion with bogus massage establishments were not unknown. The London County Council Act authorises the licensing authority to make by-laws "for the prevention of immorality" in licensed establishments, and for the keeping and inspection of records showing the persons employed and the general character of the business. Authorised officers of the L.C.C. may enter and inspect premises. An equally important point is that the by-laws may also prescribe the technical qualifications to be possessed by persons administering massage or other curative treatment. The London County Council Act of 1920 was not the first provision of its kind. There had been, for example, similar statutory requirements in Part V. of an earlier Act of 1915. The 1920 Act was closely followed in a Local Act obtained by Manchester in 1924. The Surrey County Council Act which received the Royal Assent at the end of last July contains provisions framed on the same lines but with a slightly wider definition of establishments for special treatment.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

OATS DIET IN DIABETES.

SOME years ago a German author claimed that an exclusive diet of oats has value in severe cases of diabetes mellitus, and now Dr. Oberth, of Brasov, publishes some further observations on this method of treatment. He has treated about 100 cases with varying results. The diet consists of oats given in large quantities, in the form of oat flour or flakes, together with albumin and butter, excluding all other carbohydrates and meat. The usual daily allowance consisted of oats 250 g., albumin (vegetable or from eggs) 100 g., and butter 300 g. This mixture was made into a soup and given every two hours. Wine or light brandy was occasionally allowed, and also strong black coffee. Dr. Oberth details a number of typical cases in which this régime was tried, and says that it seemed to give more favourable results than did other diets recently proposed. He does not, however, advise its adoption without careful preliminary trial in any particular patient, for he has observed cases in which it made the patient worse. The theoretical basis of this diet is under investigation.

BLOOD CHANGE AFTER HÆMORRHAGE.

In a recent lecture to the Medical Society Dr. Niculescu recorded some comparisons of the effect of hæmorrhage upon the composition of the blood in untreated persons, and in those being treated with arsenic and iron. He found that hæmorrhage produces more marked effects in the former. The leucocytes are increased, the change consisting chiefly of an increase of the polymorphonuclears, occasionally of the mononuclear cells. The solids, proteins, and total nitrogen of both blood and serum are affected to more or less the same extent. The qualitative change in the serum proteins consists in a relative increase of serum-albumin. The fibrin is increased and the coagulation-rate shortened. The blood-ash remains practically unchanged. Hæmorrhage during the administration of inorganic iron produces less deterioration in the blood than when the patient is untreated, and the administration of organic iron seems even more efficacious in preventing damage. The administration of arsenic alone has little effect except the number of leucocytes appears to be diminished instead of increased in this group of cases after hæmorrhage. The combined administration of iron and arsenic was found effective in diminishing the effects of hæmorrhage on the composition of the blood.

THE FATE OF GALL-BLADDER CASES.

A questionaire has recently been circulated to patients who have been operated on by certain well-known surgeons for gall-bladder disease, excluding cases of carcinoma. The object was to determine the results and after-effects of the operation. The statistics obtained suggest that the relief is generally permanent and the danger slight. Gall-stones had been deliberately left in one case, since the relation of the biliary ducts was so complex that no radical procedure could be attempted. Most of the other cases remained free from symptoms, and only in one case was a second operation required. Among 35 cases only one mucous and one biliary fistula resulted, and herniæ occurred in only two cases where suppuration had been extensive. Colic, due to adhesions, was reported by three patients; in two of these the appendix was removed, and in one a gastro-enterostomy had been performed. The suggestion is made that renal colic must be excluded before recurrent biliary pain colic is diagnosed, since the conditions have many symptoms in common.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

NEW PROFESSORS.

WITHIN the last year six chairs of the University of Vienna have become vacant—partly through death or illness, and partly through the age-limit. Every professor attaining the age of 70 is required by law to resign his position within the next year. The surgical professors Eiselsberg and Hochenegg resigned owing to age; the gynæcologists, Kermauner and Peham, died within half a year of each other, and both clinics for materia medica are vacant through the illness of Wenckebach and Ortner. After protracted negotiations with various scientists, the two gynæcological clinics have now been given to Prof. Georg Wagner, of Berlin, and Prof. William Weibel, of Prague. Both men were students at Vienna at the famous old school Schauta-Chrobak-Wertheim. Ortner's post has been taken over by Prof. Jagic, well known for his researches on blood and liver function; Wenckebach's is still vacant. One of the surgical clinics has been filled by Prof. Wolfgang Denk, hitherto chief of the surgical clinic of Graz, and a pupil of Eiselsberg. It is expected that the other surgical clinic will be accepted by Prof. Paul Clairmont, at present in Zürich, also a pupil of Eiselsberg. The directorship of the institute of orensic medicine, at present nominally held by

Prof. Habenda, who has long been an invalid, will be taken over by Prof. Karl Meixner, at present in Innsbruck. There will thus be many changes in university circles in the coming session.

THE LATE PROF. KOLMER.

News of the sudden death of Prof. Dr. Walter Kolmer came as a shock to the large number of his students and admirers. At the age of 52 he succumbed to an attack of heart failure while on a climbing holiday in the Alps. Prof. Kolmer was famous for his intimate knowledge of the fine anatomy of the eye, ear, and nose, and was also an authority on special sense physiology and on the morphology and histology of nervous structures. His command of comparative anatomy and histology of both the vertebrate and invertebrate animals made him an ideal director of the Institute of Morphologic Physiology attached to the University of Vienna. His early death is particularly unfortunate in that he had started building up a school of promising young researchers, none of whom is yet experienced enough to take his place.

ALARMING INCREASE OF THE NUMBER OF MEDICAL MEN.

The Municipal Board of Health published, in August, some interesting statistics dealing with the staffs of hospitals and with other medical men in practice in Vienna. It appears from the figures, that in December, 1930, 4732 practitioners and specialists were registered as entitled to practise besides 1823 dental surgeons and dentists; 11 per cent. of the medical practitioners were women, and 9 per cent. of the dentists. In the previous year there were only 4651 practitioners (475 women) and 1770 dental surgeons. The ratio of medical practitioners to population is now 1 : 3800, and that of dentists 1 : 1000. The situation is made more serious by the system of sickness insurance. During 1931 the output of graduate medical men from the University has increased still more and warnings against taking up the study of medicine have been issued by various corporations and boards. It is pointed out that the population of Vienna is slowly but steadily decreasing (from 2,000,000 in 1920 to 1,810,000 at present) and that the supply of medical men in Vienna is more than sufficient.

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

ANTIVENINE BY AIRPLANE.

The mortality from snake-bite has remained stationary in this country during the past 15 years. As a direct result of extensive research into the pathology of snake-bite conducted at the Walter and Eliza Hall Research Institute at Melbourne by C. H. Kellaway and N. Hamilton Fairley, a supply of antivenine specific against tiger snake (*Notechis scutatus*) is now commercially available. Production was effected by coöperation of the Commonwealth Serum Laboratories with the research workers, and the serum is stocked by the depôts of the Commonwealth Department of Health throughout Australia. The problem of distribution is particularly difficult owing to the rural occurrence of the snake-bite. The State of Queensland, for instance, where the highest mortality from snake-bite occurs, has an area of 670,500 square miles, which is served by five serum depôts. The difficulty of distribution is accentuated by the high cost of the serum. The recommended dose of 6000 units costs retail £8 16*s*., and the country pharmaceutical chemist cannot be expected to outlay this amount on stock which might never be used. The solution of the difficulty lies in the use of the aeroplane in providing rapid transport of the serum, and fortunately airway communications in Australia are highly developed. This method has a parallel in the organised effort of the Antivenine Institute of America.

EMPIRE CONSULTATIONS.

A few days ago a medical man in Melbourne, Victoria, was anxious to obtain without loss of time the opinion of a British neurologist on the diagnosis of a particularly difficult nerve case which was in a hospital in Melbourne. With the consent of the relatives, he established telephonic communication with London, the history of the case was given, and a subsequent telephone communication a few hours later resulted in a helpful discussion. In order to facilitate consultations in the future copies of the London Telephone Directory would have to be available at various centres.

TOLL OF THE MOTOR VEHICLE.

With the increase in the motor vehicles in commission and the growth of the population, the greater will be the opportunities for misadventure and the longer will be the roll of victims of motor-car accidents. Statistics, however, show that the three factors concerned—namely, number of motor-cars, growth of population, and number of casualties do not bear uniform relation. Figures issued by the Government statistician of deaths caused by motor accidents in New South Wales last year show an increase of 24·5 per cent. in the number of such deaths, while during the same period the population increased by 1·6 per cent., and the average number of cars registered by 13·4 per cent. In other words, the increase in the fatality-rate far exceeds the increases in the other directions. The great majority of the pedestrians involved in accidents were either under the age of 15 or over the age of 64.

MATERNITY ALLOWANCE REDUCED.

As a result of the financial stringency the Commonwealth Government has announced that, as from July 20th, 1931, the maternity allowance has been reduced from £5 to £4, and will only be paid to parents who have an income less than £260 per year. It has for long been realised that the bonus has failed in its object of increasing the birth-rate and reducing the maternal mortality-rate. The bonus was claimed by large numbers of parents who were really not in financial need of it, and the annual expenditure of £750,000 is one which the country cannot afford.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. D. C. Drake is promoted to the rank of Surg. Lt.-Comdr.

The following appointments are announced: Surg. Comdrs. R. F. Quinton to *Vivid*, for R.N. Barracks, Devonport; and G. F. Syms to *Victory XI.*, for R.N. Hospital, Portland.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. J. B. Oldham to *Victory*, for Haslar Hospital; and R. W. H. Tincker to *Pembroke*, for R.N. Barracks.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. M. D. Ahern, having attained the age for compulsory retirement, is placed on retd. pay.

Maj. (temp. Lt.-Col.) E. M. Middleton to be Lt.-Col.

(Continued at foot of next page.)

offering an attractive diversity of interest and a reasonable prospect of promotion. The evolution of a perfect scheme, the report concludes, is in the interests both of the public and of the members of the service, and although it must be gradual, its importance must never be forgotten.

MENTAL HOSPITALS AS THEY ARE TO-DAY.

ALL who are interested in the welfare of persons afflicted in mind, as well as all those concerned in the administration of our mental hospitals, should read the second part [1] of the report of the Board of Control recently published. It is the supplement of the report which appeared earlier this year, and was reviewed in our issue of July 11th (p. 90). The new volume may be considered as divided into three parts—that devoted to an account of research during the year 1930, a statistical summary of the movement of patients in the mental hospitals of England and Wales, and copies of the reports of visiting commissioners at all these institutions.

RESEARCH AND PATHOLOGICAL INVESTIGATION.

About one-third of the hospitals have sent in reviews of their work, and though these reports do not include by any means all the research that has been undertaken they show evidence that the problems of psychiatry are seriously studied. A summary of this was given by the commissioners in Part I. of their report, and it is abundantly clear from the details now added that in certain hospitals at any rate the clinical work is of a high order. Cases are reported at length, showing an examination of patients conducted with scrupulous care, and that novel as well as routine methods of treatment are tried in a systematic way. In many hospitals there is a strong staff of consultant physicians and surgeons, so that effective treatment is available in all departments of medicine and surgery, and it is heartening to find the extent to which patients in our public mental hospitals have the advantage of the new developments in therapeutics and the readiness of the medical officers to apply them. In original research, apart from the investigation of individual cases, much is being done, and it would be unfair to expect striking results in a single year. Among the subjects under research are the following: Colloid sulphur therapy, investigations of hepatic efficiency, malarial therapy in general paralysis, cerebro-spinal fluid examination, protein shock therapy, *Brucella abortus* infections, acidophilus milk therapy, physical constitution and type of mental disorder, anaerobic and aerobic bacteriology in relation to mental illness, gold-sol problem, nitrogen metabolism, and carbohydrate metabolism. Nevertheless, in reading the reports the thought arises whether the workers in our mental hospitals are not too isolated. The hospitals are often in remote districts, and it is not easy for medical officers to attend scientific meetings, and when the effort is made there may be little to interest the enthusiastic worker. There is reason for a suspicion that some of the work reported would have been more valuable if the pathologist had not been separated from the general stream of scientific thought. It is true that the Board of Control (see Part I., p. 12) are hoping to arrange for greater coördination of research. No doubt the genius in science works largely alone, goes his own way, and spends little time in digging up reports of work by others. But such men are scarce, and the ordinary research worker cannot afford to neglect what is done elsewhere. On the whole, the reports are encouraging in showing that hospital authorities are alive to the importance of research, and that not a few medical officers spend laborious hours in the pursuit of knowledge, for which there is little hope of credit or return.

RECOVERY- AND DEATH-RATES.

The statistical returns give the number of patients, admissions, discharges, and deaths, and the recovery- and death-rates in all the public mental hospitals, in the registered hospitals, and in the London and provincial licensed houses. It appears that nearly 7000 patients were discharged recovered out of an average number resident of about 124,000, and there were admitted during the year 23,000 patients. Bearing in mind the increasing number of aged infirm patients that are sent under care, and the unfavourable nature of so many others, it is satisfactory that about 7 out of every 23 patients admitted recover. In the county and borough mental hospitals in England and Wales, taken by themselves, the recovery-rate on new admissions was 33 per cent.—for males 29·5 per cent., and for females 35·5 per cent. These figures are naturally dependent on the meaning given to the word recovery. Some regard it as a return to the status quo ante, the psychosis having passed off; others as meaning the ability to resume life in the world at large; and others only consider a patient to be recovered when thoroughly sound in mind. Besides these causes of divergence, much depends on the class of patients received and the social pressure which leads to certification. Thus, it is not surprising that the recovery-rate varies greatly in different institutions. The lowest recorded is 14·6 per cent., the highest 57 per cent., whilst there are 15 out of 99 hospitals with a rate below 25 per cent. and 14 above 45 per cent. Whilst it is not safe to draw any conclusions regarding success or failure of treatment in any particular institution, the broad general fact emerges that mental hospital treatment results in an encouraging number of recoveries. We may be reminded that in the bad old days, 150 years ago, the recovery-rate was even higher than at present, but that was clearly due to the nature of admissions. A very much larger proportion of cases of acute mental excitement were admitted in those days, and in those cases the prospects of recovery are much greater than in the ordinary run of admission at the present time.

The proportion of deaths to the average daily number of patients in residence was 6·7 per cent. The highest recorded was 12 per cent., the lowest 3 per cent., and both were from hospitals in the county of York. It is interesting to note the extent to which patients are discharged from certificates although not recovered and considered of sound mind. Last year 4200 patients were so discharged. The reports do not say what became of them; but the great majority will no doubt be to the care of friends, although some may have been transferred not under certificate to public assistance institutions.

THE DAILY ROUND.

The reports of the visiting commissioners necessarily show sameness in phraseology, seeing they are constantly referring to similar matters, and that there are statutory obligations to be fulfilled. In almost all cases they express approval of the way the hospitals are administered. In no case is serious fault found;

---

[1] Lunacy and Mental Deficiency. Seventeenth annual report of the Board of Control for the year 1930. Part II. H.M. Stationery Office. 6s. 6d. Postage extra. This volume does not give any particulars of the mental deficiency institutions which are supervised by the Board.

and in not a single instance did the commissioners find anyone improperly detained. It must be remembered that the management of the public hospitals is vested in the local authority, and the Board of Control can only make recommendations for improvements. These deal frequently with overcrowding, and the urgent need in not a few hospitals for admission and convalescent blocks, so that newly admitted and those who are improving can be effectively cared for apart from the chronic patients. There are two sides to this question, for if almost all the recoverable patients are nursed apart, the remainder of the institution becomes more of an asylum than ever—merely a place of refuge for those unable to hold their own in the world at large. Conduct rather than recoverability must consequently play a large part in classification. Nevertheless the system, frequently mentioned in those reports, which places newly admitted, sensitive patients in close proximity to the noisy and degraded and chronic patients must be bad.

The increasing cultivation of handicrafts and occupations is an encouraging feature. In many hospitals specially staffed occupation centres contribute to the well-being of the patients, and some of these become the organising centre for occupation in all wards. It is pleasant, for instance, to read "in almost every ward we observed with satisfaction that patients, instead of sitting about in idleness, were encouraged, and in many instances engaged, in amusing and occupying themselves in work coming under the category of arts and crafts, the nurses, many of whom have received practical instruction, aiding and assisting them in their work"; and again, "The work done in the wards, under instructions of the ward sisters, at rug-making, fancy needlework, &c., is also worthy of note for the good it does in occupying the patients, but also as the funds obtained from sales of work can be used for amusements and other benefits to the patients." Occupation-therapy is, to an increasing extent, cultivated in our mental hospitals, and this in addition to the various trades and shops established for direct utilitarian purposes.

The commissioners frequently refer to the amount of parole given, and the extent to which leave of absence on trial is permitted. There appears to be a wide divergence of practice in these respects; in some, little freedom is permitted; in others, large sections of the hospital are administered on the open-door principle. One of the most responsible duties of the medical officer in charge is the decision whether a patient is fit for greater liberty, and this can never be shifted on to other shoulders. The impression gained on reading these reports is that the commissioners encourage a large measure of liberty. "Safety first" is a poor maxim in nearly all walks of life; in mental hospitals it can be cruel and deadening to a deplorable degree.

Much effort is directed to providing patients with books, games, entertainments, and much is done to brighten the wards and the gardens. Judging from the frequency to which reference is made to the gardens and exercise grounds used by patients, it would appear that these are often lacking in interest. Seeing that the only view of the outside world certain patients can obtain is limited to the prospect seen in and from the ward gardens, it is important these should be as attractive as possible. In some of the reports the word "airing-court" is used—an expression which suggests a limited court-yard paved with asphalt, with crowds of patients taking an airing, as in a prison-yard. We hope this picture is *unjustified*, for we find in several of the reports *appreciative* references to the ward gardens.

A *great deal of information* describing the conditions of life is given in these reports. We can hardly expect the printed reports to contain all the criticisms *and suggestions* for improvement made by the commissioners, nevertheless the general effect of their *perusal gives* a feeling of satisfaction that the insane are not only receiving skilled care and treatment, but that continuous effort is expended in making the lot of those who fail to recover as useful and as happy as their *conditions permit*.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1930 statistics of one Yorkshire city and two Lancashire county boroughs:—

Name of district and estimated mid-year population.	*Birth-rate.*	*Death-rates per 1000 of the population.* All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	*Heart disease.*	Death-rates per 1000 births. Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Sheffield .. (518,000)*	15·1	11·0	0·86	1·45	1·2	1·8	67/37	28	5·1
Blackburn .. (125,300)*	12·7	12·8	0·98	1·48	2·5	2·2	83/47	39	4·4
Preston .. (126,100)*	15·7	12·2	0·99	1·50	1·6	2·3	73/43	22	6·6

Registered stillbirths per 100 live births: Sheffield, 5·1; Blackburn, 6·8; Preston, 5·7.

* Registrar-General's estimate for 1929. The provisional Census (1931) figures are: Sheffield, 511,742; Blackburn, 122 695; Preston, 118,839.

Sheffield.

Dr. John Rennie is fortunate in the year for his first annual report. The general death-rate was the lowest ever recorded for the city. There was a very low mortality from epidemic disease and the death-rates from tuberculosis, pneumonia, and bronchitis, and the infant mortality-rate were also the lowest on record. The population was over-estimated to the extent of about 6000, but this does not appreciably affect the statistics. Thus the general death-rate of 11·0 will only become after correction 11·1. Sheffield also had a fairly good position among the 18 towns with populations exceeding 200,000. Thus it had the lowest rate of all for respiratory tuberculosis, and was only beaten by Croydon for all tuberculosis. Bradford was the only town with a lower birth-rate; there were three lower for general death-rate and seven lower for infant mortality-rate.

Since 1922 it has been customary to draw the attention of the medical attendant to every unnotified death from pneumonia. The cases notified and treated at home are visited by the Queen's nurses. There were 1568 notifications with 378 deaths. The percentage of cases removed for treatment to the City Fever Hospital and City General Hospital was 31·6. The male deaths from respiratory tuberculosis were 217, and the female deaths 138, whilst the deaths from other forms were 45 male and 41 female. At the end of 1930 the cases on the register numbered 6100. In the case of 1272 of these the sputum had been positive at some period. No case, which at any time has thus been found to be infectious, has so far been cancelled. The number of these positive cases notified from Jan. 1st, 1911, to Dec. 31st, 1922, was

CORRESPONDENCE

ALUMINIUM AND HEALTH.

To the Editor of THE LANCET.

SIR,—Your leading article last week (p. 595) will be welcomed by many readers. I entirely agree with the statements made as to the harmlessness and innocuousness of this modern non-ferrous metal on the human frame. From comparative analyses it would appear that aluminium contains fewer impurities of a possibly deleterious nature than any other metal in domestic use. During the past twenty years I have had many hundreds of workers in aluminium in large factories under my care. During this time I have had no evidence whatever of any industrial disease (such as is to be found in some other metal industries) resulting from the ingredients which are used in the manufacture of aluminium ingots.

The pure bauxite clay and cryolite used in the manufacture of the metal are of the highest purity. The former is carefully calcined and much of the fine alumina dust and hot furnace fumes must be inhaled or swallowed by the workers in the factories. Yet I have never observed the slightest signs of ill-health, temporary or chronic, which could be attributed to the inhalation of alumina. Numerous workers who have spent the greater part of their working lives, some for thirty years, are in excellent health, and show no sign of nervous depression. The health of their dependants resident in the immediate vicinity is exceptionally good. Large families are the rule. For example, one busy aluminium industrial centre has a population of 1400, including 470 thriving children.

In my own household aluminium cooking and infusing utensils are appreciated on account of their lightness, cleanliness, and easy transmission of heat. If cleaning is done by wire abrasion with a trace of soap the same articles can be kept smooth, clean, bright, and spotless for years. With a cooking surface kept perfectly smooth and free from cracks, there is much less chance of particles of organic matter being left to decompose in the pans. Another helpful point in the use of aluminium vessels is that, when bringing certain foods to the boil, they are hardly ever singed.

Alumina in the shape of pure clay has of course been given in considerable quantities in certain diseases without poisonous results. As you say, aluminium appears to be mostly eliminated by the intestinal route, and does not enter the vascular channels.—I am, Sir, yours faithfully,

LACHLAN GRANT.

Bacteriological Laboratory, Ballachulish, Argyllshire,
Sept. 14th, 1931.

DUCK EGG POISONING.

To the Editor of THE LANCET.

SIR,—A case was recently recorded in the press of a man who had died as a result of eating cake made with duck eggs. The man's wife who had also partaken of the cake became seriously ill but recovered. W. M. Scott[1] describes the occurrence of a case of acute gastro-enteritis due to salmonella. In his case the patient ate a portion of cream which had been prepared for a trifle by whipping the white of duck eggs. It has been established that bacterial infection of the egg albumin does occasionally occur, and the infecting organism is often *B. aertrycke* in duck eggs laid in and around infected ponds. The most likely mode of infection according to A. Lecoq who wrote a monograph on the subject published in Paris in 1906 is that the infected material is introduced into the oviduct of the hen or duck during copulation. The infection has been found to occur in the albumin as it is deposited around the yolk. He actually found small seeds, stones, and pieces of sticks embedded in eggs and introduced in this manner. Spencer Low thought that infection of the ovary, oviduct, and egg with salmonella could take place as part of a generalised infection of the blood. It has been found that if eggs are kept dipped in cultures of *B. aertrycke* they may become infected in a few days. As the eggs become staler, the salmonella multiply rapidly, and a portion of a stale egg would represent a truly enormous dose of the infection. Curiously enough such an egg may appear to the sense of smell as no more than slightly stale and not unsuitable for making custards or cream. When the eggs are not thoroughly cooked, or where they are merely whipped, as for a cream or a custard or an ice-cream, the danger is apparent.

In a case under my own observation the preliminary symptoms resembled an attack of migraine. There was some visual disturbance followed by the familiar hemicrania localised to the left frontal region. The hemicrania gave place to a sensation of pins and needles on one side of the body; great muscular weakness supervened, and the patient was quite unable to walk unaided. He had some facial paralysis, and a complete disorientation as to place and time. The patient became apprehensive with a fear of impending death, and he had a rigor. It is difficult to understand why in a meal consumed by many people, the patient was the only sufferer. It may be that the portion of cream allotted to the patient alone contained the specific poison. After he had been put to bed with hot bottles he had violent pains in the head, alternating with bouts of vomiting, for some time. The toxic substance was doubtless eliminated through the vomiting and this natural process suggests that the best treatment of such cases is probably gastric lavage.—I am, Sir, yours faithfully,

London, Sept. 14th, 1931. C. HORWITZ.

MECHANISM OF PULMONARY COLLAPSE.

To the Editor of THE LANCET.

SIR,—I am extremely interested in Sir Charlton Briscoe's theory of the mechanism of massive collapse of the lung. Since, however, neither marked cyanosis nor gross mediastinal shift are normally associated with either simple pulmonary deflation or simple pleurisy, it would be helpful in considering this theory to know how he would explain these concomitants of the condition.

I am, Sir, yours faithfully,

C. O. S. BLYTH BROOKE,
Chief Tuberculosis Medical Officer,
Antrim County Council.

Belfast, Sept. 13th, 1931.

To the Editor of THE LANCET.

SIR,—I yield to no one in my admiration for the enthusiasm of, and the work done by, Sir Charlton Briscoe in relation to the mechanism of lung inflation. I find it difficult, however, to follow his new theory

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

THE FINANCIAL CRISIS.

REASSEMBLY OF PARLIAMENT.

BOTH Houses of Parliament reassembled on Tuesday, Sept. 8th, for a special session to deal with the economic and financial crisis which has arisen since the adjournment for the summer recess on July 31st. The Prime Minister (Mr. Ramsay MacDonald), in the House of Commons, and Lord Reading (Secretary of State for Foreign Affairs), in the House of Lords, explained the reasons for the resignation of the Labour Government and the setting up of a national administration to balance the Budget and to restore confidence in British credit at home and abroad. The new Government was opposed in the Commons by the greater part of the Labour Party, under the new leadership of Mr. Arthur Henderson, but some Labour members decided to defy the General Council of the Trades Union Congress and to support the Prime Minister, Mr. Snowden, and Mr. J. H. Thomas in the line they have taken in joining the new Government and insisting upon a drastic policy of cuts in national expenditure, including certain social and other national services, and relief payments to unemployed persons. After a long debate a division which was taken on Tuesday night in the House of Commons resulted in a vote of confidence for the National Government by 309 votes to 249, a majority of 60.

THE SUPPLEMENTARY BUDGET.

On Thursday, Sept. 10th, the House of Commons went into Committee of Ways and Means, Sir DENNIS HERBERT, chairman of committee, in the chair.

Mr. SNOWDEN (Chancellor of the Exchequer) made his Supplementary Budget statement. He said that he was discharging one of the most disagreeable tasks that had ever fallen to his lot. It was no pleasure to call upon people to make sacrifices or to bear additional burdens, and only a consciousness that those sacrifices and burdens were necessary to avert far greater sacrifices and burdens made his task that day tolerable. It was undoubtedly a fact that nationally we had for some time past been living beyond our means, and living to a considerable extent upon our capital. The trade depression of the past ten years had reduced the yield of taxes, and at the same time had increased expenditure. Seven years ago the Unemployment Fund was paying its way. It was paying off debt. This year it was costing the Exchequer about £100,000,000. He could only meet the present situation by reducing expenditure or by increasing taxation, or by a combination of both. The nation had been under the delusion during the last few years that in these times of unparalleled depression it could maintain the expenditure of more prosperous times. Our total national and local taxation was now very near one-third of the total national income. The Government had decided that borrowing for the Unemployment Fund and the Road Fund must cease, and this decision must apply to the current financial year. There would be a loss of revenue this year from taxes of £29,000,000; from reparations under the Hoover Plan there would be a loss of revenue of £30,300,000, or a total of £59,300,000. There would have to be supplementary estimates of £813,000, and the cessation of borrowing for unemployment and the Road Fund would account for £34.000.000, or a total of just over £94,000,000. They were saving about £13,500,000 in interest on the American debt, and £5,750,000 on the Sinking Fund on that debt. These two figures amounted to £19,300,000. which, deducted from £94,000,000, gave an estimated deficit on this year's Budget of £74,700,000. It was estimated that the deficit on next year's Budget would rise to the appalling figure of £170,000.000.

Nine-tenths of the economies which the present Government proposed to make in national expenditure were approved by the late Government. The saving which these economies would effect on this year's Budget was estimated at £22,000,000 towards the £74,000,000. The charge against revenue for debt redemption was to be reduced by £13,700,000 this year and by £20.000,000 next year. To balance the Budget he would require to impose additional taxation to yield £30,000,000 for the current year, and £80,000,000 for next year. He proposed to raise the standard rate of income-tax by 6*d*., making it 5*s*. in the pound. Concurrently he proposed to revise the various personal and other allowances which determined the scope and graduation of the tax. Personal allowances to single persons would be reduced from £135 to £100, and to married persons from £225 to £150. The children's allowance would be reduced from £60 to £50 for the first child, and from £50 to £40 for each subsequent child. Housekeeper allowance would be reduced to £50. Deduction of tax under Section 40 (2) of the Finance Act, 1927, as amended by Section 10 of the Finance Act, 1930, would be altered to a deduction of tax at half the standard rate on an amount of income not exceeding £175. Sur-tax payable under Section 6 of the Finance Act, 1931, would be increased by 10 per cent. The tax on beer would be raised 1*d*. per pint, and on tobacco 8*d*. per lb. The petrol tax would be raised by 2*d*. per gallon. As from Nov. 9th, the entertainment tax would be raised to 1*d*. in every 6*d*., and extended down to sixpenny admission. The Finance Bill, Mr. Snowden said, would include clauses to facilitate the conversion of the 5 per cent. War Loan to a lower rate of interest. Such conversion would be proceeded with at the first suitable moment.

On resuming his seat Mr. Snowden was loudly cheered by Ministerial supporters. Members, including Mr. Snowden's colleagues in the new Government, rose from their seats and joined in the demonstration. The Opposition remained seated, and hurled taunts and jeers across the floor at Mr. Snowden.

Mr. GRAHAM, who was the President of the Board of Trade in the late Government, was the chief speaker for the Opposition. He said that he thought that there were abundant reasons under existing conditions for abrogating altogether the Sinking Fund for the time being. Even in these difficult times he believed the Budget could be balanced without an attack upon the rates of unemployment benefit, or upon education. The Opposition would fight on that issue in the detailed discussion in Committee. He recognised that vast new burdens were being imposed

(*Continued from opposite page.*)

of the causation of lung collapse for the following practical reasons:

(1) In the case of the average (eight out of ten) female patient, the excursion of the diaphragm in the erect posture is very slight, so limited, indeed, as to make the young radiologist describe the act of inspiration as "mainly thoracic." In the supine posture the same woman will use the diaphragm freely.

(2) After phrenic avulsion there is no lessening in the transillumination of the base of the involved lung.

I look to Sir Charlton to clear up these difficulties, as he has already solved many for myself. For the present I think the theory of temporary blocking of a bronchus, with which we are all familiar, must take pride of place.

I am, Sir, yours faithfully,

STANLEY MELVILLE.

London, W., Sept. 14th, 1931.

upon the community, but the principle of equality of sacrifice which the Prime Minister had laid down was not being carried out.

The debate on the Budget resolutions was adjourned.

THE ECONOMY BILL.

On Friday, Sept. 11th, the Prime Minister moved the second reading of the Economy Bill in the House of Commons. He said that if the economy measures which had to be enforced immediately were to be discussed at length in Parliament their efficacy would be lost. The Government would fail in their duty if they did not act swiftly and stop the cracks through which the nation's resources had been flowing unnecessarily. This Bill, therefore, laid down procedure which was as drastic as the proposals it contained. It was proposed that certain action should be taken by Orders in Council which could be issued by the Government up to one month after the passing of the Bill. The Orders in Council were limited in their operation. In regard to the Ministry of Health there would be proposed a certain re-adjustment of funds, not to diminish the efficiency of the services, but to deal with certain other funds that were going in directions which, in the opinion of the Government, were not very profitable from the point of view of health insurance. Powers would be taken by Orders in Council to transfer those funds. The only fund that appeared to be affected was the Pensions Fund. This Fund had to be revised in 1924, and the effect of the Government's proposal that certain employers' contributions should be transferred from that fund to certain general expenses of the National Health Insurance would mean that the re-examination would be made two years earlier. That was the only substantial change that was proposed in the working of that economy. The Bill would enable increased contributions to be made to the Unemployment Fund, and certain contracts to be readjusted and revised. The Government's scheme worked out as follows: £70,000,000 was to be found by economies, and £80,000,000 by taxation.

OPPOSITION AMENDMENT.

Mr. CLYNES, who was Home Secretary in the late Government, was the chief speaker for the Opposition. He moved:—

> "This House, whilst recognising the necessity for preserving the country's finances on a sound basis, cannot accept proposals which will deprive masses of the people of necessities of life whilst others remain in the enjoyment of luxuries, and will aggravate unemployment by restricting the purchasing power of wage-earners; nor can this House approve the second reading of a Bill abrogating Parliamentary control by authorising the making of Orders in Council designed to supersede existing Acts of Parliament or reverse settled national policy without the previous specific assent of the House of Commons."

He said that in regard to the cuts in the health services the view of the Opposition was that a lower standard of efficiency could not be for the industrial or social well-being of the country. A contract between the Government and monied interests was sacred, but in the lightest and most airy way the Prime Minister would vary or break a contract between the State and its citizens; men in various public services had secured conditions of remuneration and service which were now to be varied by Orders in Council. Many of these men had helped to save the country during the war. They would now be subject to the secret decisions of the smallest Cabinet of modern times. They could not have real economy by reducing the buying power of the people, and very shortly these substantial reductions would be reflected in ever-increasing unemployment, as well as in deepening distress among the more needy section of the public.

After further discussion the debate on the second reading of the Bill was adjourned.

SUMMARY OF PROPOSALS.

The Government's economy proposals include cuts in expenditure on education amounting to £10,300,000; on university grants to £150,000; and on health services to £1,250,000—or £11,700,000 out of the total economies of £70,000,000. The cuts in health services include a reduction in the remuneration of national health insurance doctors of one-ninth on the present rate of 9*s.* per year for each insured person. This reduction will take place from Oct. 1st, 1931. A similar percentage reduction is to be made from the same date from the remuneration paid to national health insurance chemists.

ADJOURNED DEBATE.

On Monday, Sept. 14th, the debate on the second reading of the Economy Bill was resumed in the House of Commons.

Mr. ARTHUR GREENWOOD (who was Minister of Health in the late Government) supported the amendment moved by Mr. Clynes on Friday, Sept. 11th. He said that the real difference between the late Government and the present Government was that the former were prepared to consider all possible proposals, however drastic, if they would achieve true equality of sacrifice. The present Government seemed to have swallowed the May Report holus-bolus, including the cuts in the rate of unemployment benefit, and had not given the country that equality of sacrifice of which some hon. Members were so fond of talking. That really was the breaking-point. He thought that the House ought to know before this Bill was given a second reading what the proposed slowing down would mean. In regard to the cut in education expenditure, was there, for example, to be a restriction of the school medical service? Was it intended to slow down the building of working-class houses, and did the Government intend to adopt that part of the May Report which suggested a reduction in the housing subsidy next April? Further, was the prolongation of the Insurance Act to go by the board before the end of the year? Was the rapidly developing maternity service, which had shown some considerable growth during the past 12 months, to come within the slowing-down process? This Bill might be the price which had to be paid to those who controlled society to-day. Noble efforts were made by hon. gentlemen opposite to do their best in the circumstances, but it appeared inevitable that in those circumstances this Bill was the price that the country had to pay to be rescued from the difficulties of the immediate crisis. But a sense of injustice was growing in the country as a consequence of this being the one method by which they must deal with the situation. While there might have been an immediate victory for existing economic and financial forces, he believed that this Bill, and the subsequent actions of the present Government, would strengthen a movement which would gain enormously in new adherents.

Sir HERBERT SAMUEL (Home Secretary) said that those who represented the Liberal party and Liberal principles and ideals felt a profound regret that their policy of national development, on which their hearts were set, was necessarily subjected to some check. But they were under the hard compulsion of financial and economic necessity, owing to the lack of resources in the nation as a whole, to carry through the measures which were found to be necessary under the circumstances. Of that necessity they were absolutely convinced. It was for that reason that many of them, who for 40 years had taken an active part in the work of social reform, now found themselves compelled, by the action of their own hands, to injure the very causes in which they passionately believed. Just as an army knew that it needed generalship, so democracy knew full well that it needed leadership, and he did not think that anything in recent weeks had met with more complete and popular approval than the formation of a small Cabinet and the swiftness of its action. Nothing would be more profoundly disapproved than the spectacle of Parliament engaging in weeks and months of debate while the financial and economic position of the nation deteriorated week by week and month by month. All successful democracies had been ready in a time of emergency to curtail their own liberties, and even the powers of their representative assemblies. Sir H. Samuel proceeded to give an account, from notes which he had made at the time, of the conferences between the Liberal and Conservative leaders and a subcommittee of the late Government during the crisis in August. He gave details of the figures which were communicated to the party leaders as to the economies which the late Cabinet would be prepared to carry out, and stated that, except in the section relating to unemployment, the items in the White Paper produced by the present Government were, with very small differences, item for item exactly the items that were communicated to them on behalf of the late Government as those regarded by the late Cabinet as proper economies if economies had to be made along those lines. The conclusion which the House must draw was that if the right hon. gentlemen, who now formed part of the Opposition, had remained in office and had had the responsibility for dealing with the situation, and if all their complete proposals had been accepted with regard to unemployment benefit, direct taxation, and so forth, this was the very list of economies which they would have proposed.

After further discussion,

Mr. CHAMBERLAIN (Minister of Health), in winding up the debate on behalf of the Government, said that the amendment asked the House to reject the Bill on two grounds. First, on the ground of the alleged unfairness of its provisions, and, secondly, on the ground of the method of its procedure. The procedure adopted in this Bill was not without precedent. In the opening days of the Great War an Act was passed authorising the making of Orders in Council for public safety and the defence of the realm; this Bill had precisely the same purpose. In spite of the doubts of some members of the Opposition, it could not be seriously contested that a crisis did exist, and a very serious crisis. They found themselves in this position: that to-day instead of the Government being in the dock it was the members of the Labour Party. What had been clearly established was this, first, that the late Government accepted economies amounting to £56,000,000, and, secondly, that those £56,000,000 included every single one of the proposals which were before the House that day, except the 10 per cent. cut in unemployment benefit. What, then, was the use of the Opposition pretending that they did not know what was included in the cut which was to take place? Everyone admitted that these proposals must have an immediate effect on increasing unemployment, but to complete the programme they needed a constructive programme to stimulate the progress of industry and agriculture. The country could not long await that constructive programme. The sooner that Parliament concluded this business the sooner the Government or its successors would be able to begin on the work of building up.

SECOND READING CARRIED.

The Bill was read a second time by 310 to 253—Government majority 57.

HOUSE OF COMMONS.

MONDAY, SEPT. 14TH.

Stamp Duty on Patent Medicines.

Mr. MILLS asked the Chancellor of the Exchequer if he was aware that thermogene, antiphlogistine, and many other patent medicines were now being sent to qualified chemists without revenue stamps of 3*d.* and 6*d.* attached; and whether, as chemists were suffering from this recent policy, he would consider what steps should be taken to protect the revenue.—Mr. SNOWDEN replied: The law provides for exemption from medicine stamp duty in favour of "known, admitted, and approved" remedies when sold under certain conditions by duly qualified chemists or druggists. I am aware that certain manufacturers have taken steps to bring their preparations within the scope of that exemption, but this is not a matter in which I can interfere.

Narcotics Convention.

Lieut.-Colonel FREMANTLE asked the Under Secretary for Foreign Affairs whether British ratification of the 1931 Narcotics Limitation Convention had yet been decided upon; and, if not, when was a decision regarding ratification likely to be made.—Captain EDEN replied: I am informed that legislation amending the Dangerous Drugs Acts in certain respects will be necessary before the Convention for the Limitation of the Manufacture of Narcotic Drugs can be ratified. The matter is under consideration.

Headlights on Motor-cars.

Mr. DAY asked the Minister of Transport when he proposed to make regulations for the purpose of regulating the use of powerful headlights on motor vehicles.—Mr. PYBUS replied: My predecessor circulated draft regulations on this subject to motoring organisations, and to other organisations interested, and also to the press. The comments received in consequence are at present under consideration in my department. I am not yet in a position to make any statement as to the final form of the regulations.

Panel Practitioners' Remuneration.

Mr. RHYS DAVIES asked the Minister of Health if he would show in tabular form, annually in each case, the number of medical practitioners acting as panel doctors under the National Health Insurance scheme since it came into operation; the total amount paid to such panel doctors; the number of doctors receiving payment in this connexion; the number of insured persons; and the capita grant per insured person paid.—Mr. CHAMBERLAIN replied: The figures are as follows:—

Year.	Insurance doctors.	Total payments to insurance doctors.	Number of insured persons.	Capitation fee.
		£		
1913	12,674	3,858,000	11,521,772	7*s.* 6*d.* (on average).
1914	12,868	3,673,000	12,425,421	
1915	12,675	3,470,000	10,116,920	
1916	12,321	3,353,000	10,333,003	
1917	11,984	3,845,000	10,622,562	
1918	11,675	3,611,000	10,679,901	
1919	11,346	4,052,000	11,454,616	
1920	11,620	7,403,000	12,931,763	11*s.* 0*d.*
1921	12,216	7,821,000	13,225,000	
1922	12,531	6,773,000	13,275,000	9*s.* 6*d.*
1923	12,862	6,670,000	13,295,000	
1924	13,211	6,476,000	13,672,000	9*s.* 0*d.*
1925	13,823	6,518,000	13,695,000	
1926	14,432	6,661,000	14,102,000	
1927	14,952	6,831,000	14,363,000	
1928	15,269	7,037,000	14,814,000	
1929	15,563	7,109,000	14,959,000	
1930	15,750	7,300,000	15,398,000	

TUESDAY, SEPT. 15TH.

Ambulances in Irish Free State.

Mr. ROSS asked the Secretary of State for Dominion Affairs whether he was aware that, by a recent enactment of the Irish Free State, fire-engines and ambulances from Northern Ireland were prevented from going to the assistance of persons obliged to live in that Dominion, even where such assistance could not otherwise be provided; and whether he would make representations to the Government of the Dominion as to this situation.—Mr. MALCOLM MACDONALD (Under Secretary of State for Dominion Affairs) replied: The matter in question is entirely one for His Majesty's Government in the Irish Free State. I understand that no restrictions are imposed upon fire-engines and ambulances entering the Irish Free State from Northern Ireland when need arises.

BETHLEM HOSPITAL: ANNUAL REPORT.—The annual statement of accounts shows that the ordinary income for the year exceeded expenditure by nearly £3000. The cost of furniture, &c., for the new hospital at Monks Orchard has been charged to extraordinary expenditure, with the result that there was a debit balance of more than £9000. The accommodation is for 250 patients, and at present 160 have been admitted. Progress has been made in the science and treatment laboratories. Dr. Alastair McGregor has been appointed director of physiotherapy and Dr. William Brown director of the psychological department. The research department, under the direction of Dr. Lovell, the hospital pathologist, is widening its scope, and sister hospitals have been informed of the willingness of the governors to consider applications for affiliation to the hospital for the purpose of research and for the undertaking of analytical work.

MEDICAL NEWS

University of London: Lectures in Pathology.

The following lectures will be given on Tuesdays, at 5.15 P.M., at University College Hospital Medical School, Gower-street, W.C.: Oct. 13th and 20th, Prof. J. C. G. Ledingham, F.R.S., on Resistance to Infection, natural and induced. Oct. 27th and Nov. 3rd, Prof. C. R. Harington, F.R.S., on the Chemistry and Functions of the Thyroid Gland. Nov. 10th and 17th, Miss Harriette Chick, D.Sc., on Vitamins and Disease. Nov. 24th, Dec. 1st and 8th, Dr. R. T. Grant, on the Pathology of Endocarditis. Admission is free to medical students and graduates.

University College Hospital Medical School.

The annual post-graduate demonstrations arranged for the benefit of old students will take place on Oct. 15th and 16th. Among the subjects dealt with will be: Diet in Gastric Ulcer, Perineal Tears, Chronic Chest Ailments in Young Children. Recent Changes in the Treatment of Diabetes, Skiagenic Tuberculosis of the Lungs, and Acute Arsenical Poisoning.

The annual dinner of old students will be held at the Hotel Victoria, London, W.C., at 7.30 P.M. on Oct. 16th, and the annual dinner of past and present women students of University College Hospital will be held at the same time at the Piccadilly Hotel.

St. George's Hospital Medical School.

Lord Ponsonby will present the prizes and deliver the inaugural address at 3 P.M. on Oct. 1st in the Board Room of St. George's Hospital. The annual dinner of the Medical School will take place at the Hyde Park Hotel, Knightsbridge, London, S.W., at 7.45 P.M. on the same day.

As a result of the annual examination, the following *Entrance Scholarships and Exhibitions* have been awarded: J. A. Lewis, the William Brown Senior Exhibition of £120; Morvyn Williams, the William Brown Junior Exhibition of £80; F. R. Berridge and R. D. Holloway, an Anne Selina Fernee Scholarship of £80 each; A. N. F. Critchley and R. A. Binning, an Anne Selina Fernee Exhibition of £60 each; C. E. Elliott, the Devitt-Pendlebury Scholarship of £50, and S. Ginsburg, an Entrance Exhibition of £40.

King's College Hospital Medical School.

The opening of the winter session will take place at the Medical School, Denmark-hill, S.E., on Oct. 1st, at 2.15 P.M. The introductory address will be given by Prof. H. R. Dean, Professor of Pathology in the University of Cambridge. Mr. A. D. Power, vice-chairman of the committee of management of King's College Hospital, will preside. The annual dinner of past and present students will be held the same evening at 7.30 P.M. at the Connaught Rooms, Mr. L. Vernon Cargill presiding.

A series of post-graduate lectures, free to all medical practitioners, will be delivered in the lecture theatre of the Medical School on Thursdays at 9 P.M. from Oct. 8th to Dec. 17th inclusive, and from Jan. 7th to March 17th. The opening lecture will be delivered by Sir StClair Thomson on Cancer of the Larynx. Subsequent lectures will be announced weekly in our Medical Diary.

St. Mary's Hospital Post-graduate Course.

The annual week-end post-graduate course, open to all medical practitioners without fee, will be held from Oct. 2nd to Oct. 4th inclusive in the library of the Medical School. The subjects to be discussed include the treatment of common fractures, rheumatoid arthritis, chronic cough, chronic indigestion, colitis, and slow labour. Other lecturers will deal with diseases of the tongue, prenatal care, surgical operations in old people, toxæmias of pregnancy, common disabilities of the foot, new methods of genito-urinary surgery, fever without signs, the treatment of chronic cough.

National Council for Mental Hygiene.

A series of lecture-discussions will be delivered in the lecture room of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Thursdays, at 5.15 P.M., on Oct. 22nd, 29th, Nov. 12th, 19th, 26th, and Dec. 10th. The subjects will be the Prevention and Treatment of Nervous Breakdown, Sex Education, Crime and Punishment, the Mind of a Child, Marriage and Parenthood, and Psycho-analysis. The lectures will be delivered respectively by Dr. A. Helen Boyle, Dr. Israel Feldman, Dr. Letitia Fairfield, Dr. William Moodie, Dr. Doris M. Odlum, and Dr. Ernest Jones. Further particulars can be obtained from the secretary of the council at 78, Chandos House, Palmer-street, London, S.W. 1.

Surgical Instrument Manufacturers' Association.

The annual dinner of this association will take plac the Holborn Restaurant, London, on Friday, Oct. when Mr. T. P. Dunhill, assistant surgeon to St. Ba lomew's Hospital, and Mr. A. R. Melhuish, President of the Pharmaceutical Society, will be present as guests.

Public Health and the Gas Industry.

A discussion on this subject will be held at 10.15 A.M. on Sept. 29th at the Rougemont Hotel, Exeter, in conne with the conference of the British Commercial Gas Asso tion. The discussion will be opened by Dr. Meredith Dav and will be followed by one on gas as a source of radi energy for treatment of disease, to be opened by Sir Leon Hill, F.R.S.

North Middlesex County Hospital, Edmonton.

The new radiological pavilion will be opened by Mr. George Marlow Reed, chairman of the Middlesex County Council, at 3 P.M. on Sept. 29th, and the nurses' home extension will be opened by Mrs. Marlow Reed at 3.30 P.M.

Reopening of Tenbury Hospital.

This hospital, which was closed two years ago owing to lack of support, has now been reopened. It is to be run in conjunction with the District Nursing Association.

Westbury Cottage Hospital.

This Wiltshire hospital has been rebuilt at a cost of £11,000, and the Duchess of Beaufort formally opened it last week. The cost per bed, including furnishing and equipment, was £550.

Nelson Hospital, Merton.

An extension of this hospital at Merton, Surrey, has recently been opened. It includes maternity and antenatal departments, with accommodation for 21 patients, who will pay according to their means. The extensions, reconstructions, and equipment have cost £45,000.

Maternity Home at Craigmonie.

Lady Bertha Dawkins recently opened new buildings at the Ida Merry Maternity Home at Craigmonie, Inverness, which contains ten beds, with nursery and isolation wards. The original home was established some years ago by the Hon. Mrs. Merry, of Belladrum.

A Debt-free Hospital.

Countess Fitzwilliam recently opened a new out-patients' department at Rotherham Hospital which has cost £22,500. The whole of the money has been provided, and the hospital itself is out of debt. The new building includes departments for massage, casualties, sunlight, dentistry, ear, nose, and throat treatment.

Northampton Isolation Hospital.

At a cost of about £5000 much enlarged provision has been made for the service of this hospital at Kingsthorpe. Many bedrooms and other accommodation for the staff have been provided, and the additions were opened last week by the Mayor of Northampton, Councillor E. Ingman.

York County Hospital.

It has been decided to establish a contributory scheme for the York County Hospital, which has an overdraft of about £18,000. Between Jan. 1st and August 1st the hospital admitted 104 accident cases, the treatment of which cost over £1000, towards which only £179 was received; of this one patient paid £88.

Davos Tuberculosis Meeting.

A meeting organised by the Davos Medical Society will be held from Oct. 5th to 10th, the subjects for discussion being (1) Development and Course of Pulmonary Tuberculosis; (2) Extra-pulmonary Tuberculosis; (3) Collapse Therapy. Lectures will be given at the Palace Hotel, Davos-Platz, in four languages, by specialists from many parts of Europe. Delegates from this country include Dr. H. Batty Shaw, Sir Henry Gauvain, Dr. L. S. T. Burrell, Dr. F. G. Chandler, and Mr. H. Morriston Davies. Prof. L. Brauer, of Hamburg, will give a public lecture on the significance of research institutes for tuberculosis. Accommodation at reduced terms will be available in nine hotels, and Messrs. Thomas Cook and Son are making the travelling arrangements. Further information from the President of the Medical Society, Davos-Platz, Switzerland, to whom names should be sent before Oct. 1st.

Medical Diary

nformation to be included in this column should reach us proper form on Tuesday, and cannot appear if it reaches later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LOWSHIP OF MEDICINE AND POST-GRADUATE EDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 21st, to SATURDAY, Sept. 26th.—INFANTS HOSPITAL, Vincent-square, S.W. Second week of post-graduate course in Diseases of Infants. Every afternoon at 2 P.M. WESTMINSTER HOSPITAL, S.W.—Second week of course in Medicine, Surgery, and the Specialties. Men only. Daily, 10.30 to 5.30. Further particulars from the Fellowship of Medicine.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, London, W.C.

FRIDAY, Sept. 25th.—4 P.M., Mr. W. A. Mill: Ear-ache in the Normal Ear.

MARK'S HOSPITAL, City-road, E.C.

THURSDAY, Sept. 24th.—4.30 P.M., Mr. L. E. C. Norbury: Benign Strictures of the Rectum.

Appointments

Certifying Surgeons under the Factories and Workshops Acts: CAMPBELL, E. G., M.B., Ch.B. Dub. (Ripley, W. Riding); DAVIDSON, J., M.B., Ch.B. Sheffield (Hillsborough, W. Riding); PETCH, H. C., M.B., Ch.B., Leeds (Pateley Bridge, W. Riding); SADLER, C. G. A., M.R.C.S. Eng., L.R.C.P. Lond. (Teddington, Middlesex); MCGIBBON, J. H. (Higham Ferrers, Northampton), and WILSON, W. M. (Littleport, Cambridge).

Vacancies

For further information refer to the Advertisement columns.

Aberdeen Royal Infirmary.—Jun. Asst. Surgeon.

Aberdeen Royal Mental Hospital.—Second Asst. Phys. £100.

Altrincham General Hospital.—Jun. H.S. At rate of £120.

[illegible]bury, Horton General Hospital.—Res. M.O. At rate of £150.

Birmingham City Education Committee.—Two Asst. School M.O.'s. Each £500.

Birmingham General Hospital.—Med. Reg. and Res. M.O. £155.

Birmingham, [illegible] Dept.—Asst. M.O. for Tuberculosis Section. £400.

Birmingham, St. Chad's Hospital.—Res. M.O. £100.

Birmingham, Selly Oak Hospital.—Cas. O. At rate of £200.

Blackburn County Borough.—Asst. School M.O. and Asst. M.O.H. £700.

Bradford City Sanatorium, Grassington.—H.P. £225.

Burnley County Borough.—Asst. M.O.H. and Asst. School M.O. £500.

Cardiff, King Edward VII. Welsh National Memorial Assn.—Two Area Tuberculosis Physicians. Each £750.

Cardiff Royal Infirmary.—Two H.S.'s to Special Departments. Also H.P. and H.S. All at rate of £50.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Assts. for Out-patient Dept.

Cheadle, Cheshire, Barnes Convalescent Hospital.—Res. M.O. £250.

Chester, Royal Infirmary.—H.S. £150.

Chester, Wrenbury Hall Tuberculosis Training Colony.—H.P. £250.

City of London Hospital for Diseases of Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.

Eastern Dispensary, Leman-street, E.—Ophth. Surg.

Exeter, Royal Devon and Exeter Hospital.—Cas. O. and H.S. to Special Depts. Each at rate of £150.

Gateshead Dispensary.—Asst. M.O. £300–£350.

Glasgow, Woodilee Mental Hospital, Lenzie.—Jun. Asst. M.O. £300.

Golden-square Throat, Nose, and Ear Hospital, W.—Hon. Surg.

Great Yarmouth General Hospital.—H.S. £140.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Hammersmith Hospital, Ducane-road, W.—Asst. M.O. £350.

Hertford, Ware Park Sanatorium.—Asst. M.O. £300.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. and H.P. Each at rate of £100. Also Clin. Asst.

Kettering and District General Hospital.—Res. M.O. At rate of £200.

Leicester Royal Infirmary.—Asst. Pathologists. £400. Res. Asst. Anæsthetist. At rate of £250. Also Two Surgical Dressers. 10s. 6d. per week.

Liverpool Eye and Ear Infirmary, Myrtle-street.—H.S. to Ophth. Dept. £120.

Liverpool Heart Hospital.—Hon. Asst. Physician.

Liverpool Royal Southern Hospital.—H.P., M.O. to Spec. Depts., [illegible]s. Anæsthetist. All at rate of £60.

Liverpool, Smithdown-road Hospital.—Res. Asst. M.O. £200.

L.C.C. Mental Hospital Service.—Asst. M.O. £475.

London Female Lock Hospital, Harrow-road, W.—H.S. At rate of £150.

London Homœopathic Hospital, Great Ormond-street, W.C.—Three Res. M.O.'s. All at rate of £100.

Macclesfield General Infirmary.—Second H.S. At rate of £150.

Manchester, Ancoats Hospital.—Res. Surg. O. £200.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester, Royal Infirmary.—Jun. Asst. M.O. for Radiological Dept. £400.

Margate Royal Sea Bathing Hospital for Surgical Tuberculosis.—H.S. At rate of £200.

Maudsley Hospital, Denmark Hill, S.E.—Deputy Med. Supt. £850.

Metropolitan Hospital, Kingsland-road, E.—Sen. and Jun. H.P.'s and H.S.'s. Also Two H.S.'s. All at rate of £100.

Middlesex County Council, County Tuberculosis Sanatorium, South Mimms.—Asst. Res. M.O. £400.

National Hospital, Queen-square, W.C.—Asst. Registrar. £200.

Norwich, Norfolk and Norwich Hospital.—H.S. for Ear, Nose, and Throat. £120.

Nottingham City Education Committee.—Whole-time Jun. Asst. School M.O. £500.

Nottingham General Dispensary, Broad-street.—Res. Surgeon. £250.

Nottingham General Hospital.—H.P. At rate of £150.

Portsmouth Royal Hospital.—H.P. and Cas. O. At rate of £130 and £100 respectively.

Preston and County of Lancaster Royal Infirmary.—H.S. At rate of £150.

Queen's Hospital for Children, Hackney-road, E.—H.P. At rate of £100.

Queen Mary's Hospital for the East End, E.—Surgical and Dental Anæsthetists. 50 guineas and £25 respectively.

Richmond, Surrey, Royal Hospital.—Hon. Surg. to Ear, Nose, and Throat Dept. Also Jun. H.S. At rate of £100.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal London Ophthalmic Hospital, City-road, E.C.—Sen. Res. O. £150.

Royal National Orthopædic Hospital, 234, Gt. Portland-street, W.—Hon. Asst. Surgeon.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. At rate of £200. Also H.S. At rate of £100.

St. Bartholomew's Hospital, E.C.—Dental H.S. £80.

St. Giles' Hospital, Brunswick-square, Camberwell, S.E.—Part-time Radiologist. At rate of £236 5s.

St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C.—Jun. Hon. Med. Reg.

St. Mary's Hospital, W.—2nd Asst. Pathologist. £250. Also Obstetric Registrar. £50.

Salford Royal Hospital.—Res. H.S.'s to Special Depts. Also Cas. H.S. All at rate of £125.

Scarborough Hospital and Dispensary.—Two H.S.'s. Each at rate of £175.

Sheffield, Jessop Hospital for Women.—Sen. Res. M.O. £200. Also Res. M.O. and two Asst. H.S.'s. At rate of £150 and £100 respectively.

Southampton County Borough.—Asst. M.O.H. £500.

South London Hospital for Women, Clapham-road, S.W.—H.P. and two H.S.'s. Each at rate of £100.

Stafford, Staffordshire C.C. County Bacteriological Laboratory.—Asst. Bacteriologist and Pathologist. £700.

Swansea, Infectious Diseases Hospital.—Res. M.O. £350.

Taunton and Somerset Hospital.—Asst. H.S. At rate of £100.

Wells, Somerset, Mental Hospital.—Asst. M.O. £350.

West Riding of Yorkshire County Council.—Temp. Sch. Med. Inspectors. £175.

Wolverhampton Royal Hospital.—H.S. for Orthopædic Dept. At rate of £100.

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Alston (Cumberland).

Births, Marriages, and Deaths

BIRTHS.

BINGHAM.—On Sept. 11th, the wife of Thomas H. Bingham, M.D., of Reigate, of a daughter.

DAVIES.—On September 15th, at 1, Pleydell-avenue, W.6, to Dorothy, the wife of G. I. Davies, M.D., D.P.H.(Lond.)—a son.

GUNN.—On Sept. 11th, the wife of Alistair Gunn, M.D., F.R.C.S., of Lawn-road, Hampstead, of a son.

HOCKING.—On Sept. 15th, the wife of Dr. F. D. M. Hocking, of 140, Harley-street, of a daughter.

REID.—On Sept. 8th, at Welbeck-street, W., the wife of Ronald Reid, M.S., F.R.C.S., of a daughter.

SAMUEL.—On Sept. 9th, at Dowlow Asshe, Vallance-road, Muswell Hill, to Dr. E. Summerskill, wife of Dr. E. Jeffrey Samuel—a daughter (Shirley).

WHITE.—On Sept. 9th, at Nailsea, the wife of Dr. R. F. White, of a daughter.

WOOLRICH.—On Sept. 8th, at Sanderstead, Surrey, the wife of Dr. W. Grant Woolrich, of a daughter.

DEATHS.

CROOKE-LAWLESS.—On Sept. 14th, at Folkestone, Surg. Lt.-Col. Sir Warren Roland Crooke-Lawless, aged 68.

JAMES.—On Sept. 9th, at Warwick-road, Upper Clapton, Charles Alfred James, M.R.C.S., L.R.C.P., D.P.H.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

THE Minister of Health has appointed Captain D. W. Gunston, M.C., M.P., to be his Parliamentary Private Secretary (unpaid).

NOTES, COMMENTS, AND ABSTRACTS

BIOLOGICAL APPROACH TO HEALTH PROBLEMS.

At the annual congress of the Royal Sanitary Association of Scotland, held at Largs, in Fifeshire, Dr. Parlane Kinloch, chief medical officer of the Department of Health, the president, gave an address on the Science of Life. He showed that the administrative health problems of to-day could be safely approached only on a biological basis. He expressed his conviction that the life of members of a modern civilised community must be founded on scientific thinking and living. The health services must draw their sanctions in the last resort from the science of biology. Our gains in biological knowledge in the past 300 years, and, indeed, in the last 30 years, had far exceeded the gains made in the previous 30,000 years. He pleaded for the acceptance of a national biological policy, which would deliberately seek new knowledge and apply it to the end that, as a race, we might grow in health and vigour, resource, and adaptability. In physiology and medicine a reorientation of outlook was needed, so that assessment of fitness and assessment of the degree of incapacity would become of dominant importance. The medical research organisation would push forward the boundaries of biological knowledge, and the central and local authorities would secure the experimental application to the community of the discoveries of medical science. The true basis of administrative measures was a nutritional service. So long as the authorities ignored the achievements of biological research, so long would much of the health services remain a waste of effort. He indicated also the beginning that should be made in mental health service in Scotland by the establishment of four regional psychiatric clinics in the four university cities. At these clinics the early disharmonies leading to mental illness would be defined and controlled, and mental patients sorted out and allocated for appropriate treatment. This would have an immediate effect in reducing the number of certified lunatics as would also a review of certified cases, together with the development of treatment on a voluntary basis. The number of certified lunatics might in this way be reduced by one-third. The address was an inspiring exposition of fundamental principles as applied administratively.

THE DEVELOPMENT OF YOUNG CHILDREN.

Many close observers of the lives of young children have written large and valuable treatises on the thinking and behaviour of the young, but even such classical writers as Wilhelm Stern and J. Piaget, for example, have erred in obtaining much of their information through questions. Mrs. Isaacs records[1] a new and fascinating departure from this method. The data of the lives of the little children in her school are given verbatim in her book. She has taken daily notes of the remarks made and actions performed in what was almost entirely a child world, the grown-ups being largely in the background or joining in only when necessary on the child's level. The result is a curious record of the discovery, reasoning, and thought of children and of their biological interests. Some readers may find this record dull and disconnected, but those who are pursuing child psychology from the educational and from the psycho-pathological point of view will discover much information on the natural pursuits and ideas of the child; many difficulties will be cleared up, and many unacceptable theories more easily understood. In an initial chapter, Mrs. Isaacs shows in what way her methods differ from those of other observers. She promises to make no interpretations while collecting data, nor does she allow herself or her fellow-observers to do more than to describe objectively what the child actually did and said, and the circumstances in which speech and a took place. In this respect she differs from Pi who definitely limits his field of inquiry, and ther the scope of his conclusions, by putting question

Mr. Isaacs has added a considerable chapte children's "Why" questions. This is a cl reasoned classification and analysis of the fau attitude of children towards their environmer their efforts to coördinate their world and to re the disparate elements of perception. This ch is of great value, and in our view the authors' cr attitude to the anthropomorphic views on the cl world put forward by Prof. Piaget is justified.

No workers in the field either of normal (abnormal child psychology can afford to ig a book by Prof. Katharine Bridges on the pre-s child.[2] It is based upon a prolonged study of behaviour of children in contact with one ano and with their elders, and therefore illustrates manner in which the emotional life of the influences, and is influenced by, its social milieu. author starts out with a method which was ded by preliminary experiment with a provisional sch The working out of a social development scale have entailed a great deal of labour. The man observations are at first sight very bewildering, they provide a warning to those who use bro categories that analysis of child behaviour depend upon detailed observations. The therefore of the thesis will depend upon the s of a larger number of cases than are here dealt to make them statistically comparable with number of observations themselves. Workers in same field would be wise if they used the aut scale in order to register their own records. A ch is devoted to the McGill Nursery Scale, and t who are interested in the scientific study of chil rather than in chatty descriptions would do well to this their close attention. The volume is illu by many attractive photographs of children at pl

PRESCRIPTIONS FOR THE DEAF.

In an article on aids to the deaf publishe the *Wireless Magazine* for September, 1931, C. Balbi comments on the fact that while those poor sight seek spectacles, the deaf do not, as a w avail themselves of aids to hearing. In his this is because spectacles are prescribed on scie lines, and the benefits obtained are instantaneous lasting, while aids to the deaf are chosen hapha by the patient himself, and may be found unsui after purchase. Simple magnification does necessarily help the deaf person, since amplif appliances introduce distortion. This distortion he says, be harnessed to supplement the parti range in which the patient's hearing is defec In order to ascertain this range, a standard testing apparatus, known as the audiograph, has devised. When the range is charted, a prescri can be formulated, for example for a bass deaf pe A micro-telephone, with the appropriate character can then be chosen, or an apparatus containi valve amplifier can be used. Such an appa is necessarily more bulky, but it can be adj by means of filter circuits to conform to the spec tion required. Mr. Balbi suggests that while a port micro-telephone will continue to be popular characteristic should be prescribed. He recomm for occasions where portability is not essential, th of an appropriately adjusted amplifier telephone.

After Sept. 21st the address of the offices warehouses of Messrs. Coates and Cooper, (Medical and Pharmaceutical Products), will 94, Clerkenwell-road, London, E.C.1. Telepho Clerkenwell 4100.
